$$\text{Datarate}[\text{samples} / \text{s}] = \frac{f_{\text{DATAIN\_RATE}}}{F_{\text{OSR}} \cdot (I_{\text{OSR}} - 1 + 4) + (2 + 1)} \quad \dots \text{FAST} = 0, \text{FastSinc filter}$$

or

$$\text{Datarate}[\text{samples} / \text{s}] = \frac{f_{\text{DATAIN\_RATE}}}{F_{\text{OSR}} \cdot I_{\text{OSR}}} \quad \dots \text{FAST}=1 \text{ or any filter bypass case } (F_{\text{OSR}} = 1)$$

where:  $f_{\text{DATAIN\_RATE}}$ ...input data rate from ADC or from CPU/DMA

**Note:** Availability of the input from internal ADC is device dependent, see [Table 155: DFSDM1 implementation](#).

The right bit-shift of final data is performed in this module because the final data width is 24-bit and data coming from the processing path can be up to 32 bits. This right bit-shift is configurable in the range 0-31 bits for each selected input channel (see DTRBS[4:0] bits in DFSDM\_CHyCFGR2 register). The right bit-shift is rounding the result to nearest integer value. The sign of shifted result is maintained - to have valid 24-bit signed format of result data.

In the next step, an offset correction of the result is performed. The offset correction value (OFFSET[23:0] stored in register DFSDM\_CHyCFGR2) is subtracted from the output data for a given channel. Data in the OFFSET[23:0] field is set by software by the appropriate calibration routine.

Due to the fact that all operations in digital processing are performed on 32-bit signed registers, the following conditions must be fulfilled not to overflow the result:

$$\begin{aligned} F_{\text{OSR}}^{F_{\text{ORD}}} \cdot I_{\text{OSR}} &\leq 2^{31} \quad \dots \text{for Sinc}^x \text{ filters, } x = 1..5 \\ 2 \cdot F_{\text{OSR}}^2 \cdot I_{\text{OSR}} &\leq 2^{31} \quad \dots \text{for FastSinc filter} \end{aligned}$$

**Note:** In case of filter and integrator bypass ( $I_{\text{OSR}}[7:0]=0$ ,  $F_{\text{OSR}}[9:0]=0$ ), the input data rate ( $f_{\text{DATAIN\_RATE}}$ ) must be limited to be able to read all output data:

$$f_{\text{DATAIN\_RATE}} \leq f_{\text{APB}}$$

where  $f_{\text{APB}}$  is the bus frequency to which the DFSDM peripheral is connected.

#### 24.4.14 Signed data format

Each DFSDM input serial channel can be connected to one external  $\Sigma\Delta$  modulator. An external  $\Sigma\Delta$  modulator can have 2 differential inputs (positive and negative) which can be used for a differential or single-ended signal measurement.

A  $\Sigma\Delta$  modulator output is always assumed in a signed format (a data stream of zeros and ones from a  $\Sigma\Delta$  modulator represents values -1 and +1).

**Signed data format in registers:** Data is in a signed format in registers for final output data, analog watchdog, extremes detector, offset correction. The msb of output data word represents the sign of value (two's complement format).

#### 24.4.15 Launching conversions

**Injected conversions** can be launched using the following methods:

- Software: writing '1' to JSWSTART in the DFSDM\_FLTxCR1 register.
- Trigger: JEXTSEL[2:0] selects the trigger signal while JEXTEN activates the trigger and selects the active edge at the same time (see the DFSDM\_FLTxCR1 register).
- Synchronous with DFSDM\_FLT0 if JSYNC=1: for DFSDM\_FLTx ( $x>0$ ), an injected conversion is automatically launched when in DFSDM\_FLT0; the injected conversion is started by software (JSWSTART=1 in DFSDM\_FLT0CR2 register). Each injected conversion in DFSDM\_FLTx ( $x>0$ ) is always executed according to its local configuration settings (JSCAN, JCHG, etc.).

If the scan conversion is enabled (bit JSCAN=1) then, each time an injected conversion is triggered, all of the selected channels in the injected group (JCHG[7:0] bits in DFSDM\_FLTxJCHGR register) are converted sequentially, starting with the lowest channel (channel 0, if selected).

If the scan conversion is disabled (bit JSCAN=0) then, each time an injected conversion is triggered, only one of the selected channels in the injected group (JCHG[7:0] bits in DFSDM\_FLTxJCHGR register) is converted and the channel selection is then moved to the next selected channel. Writing to the JCHG[7:0] bits when JSCAN=0 sets the channel selection to the lowest selected injected channel.

Only one injected conversion can be ongoing at a given time. Thus, any request to launch an injected conversion is ignored if another request for an injected conversion has already been issued but not yet completed.

**Regular conversions** can be launched using the following methods:

- Software: by writing '1' to RSWSTART in the DFSDM\_FLTxCR1 register.
- Synchronous with DFSDM\_FLT0 if RSYNC=1: for DFSDM\_FLTx ( $x>0$ ), a regular conversion is automatically launched when in DFSDM\_FLT0; a regular conversion is started by software (RSWSTART=1 in DFSDM\_FLT0CR2 register). Each regular conversion in DFSDM\_FLTx ( $x>0$ ) is always executed according to its local configuration settings (RCONT, RCH, etc.).

Only one regular conversion can be pending or ongoing at a given time. Thus, any request to launch a regular conversion is ignored if another request for a regular conversion has already been issued but not yet completed. A regular conversion can be pending if it was interrupted by an injected conversion or if it was started while an injected conversion was in progress. This pending regular conversion is then delayed and is performed when all injected conversion are finished. Any delayed regular conversion is signaled by RPEND bit in DFSDM\_FLTxRDATAR register.

## 24.4.16 Continuous and fast continuous modes

Setting RCONT in the DFSDM\_FLTxCr1 register causes regular conversions to execute in continuous mode. RCONT=1 means that the channel selected by RCH[2:0] is converted repeatedly after '1' is written to RSWSTART.

The regular conversions executing in continuous mode can be stopped by writing '0' to RCONT. After clearing RCONT, the on-going conversion is stopped immediately.

In continuous mode, the data rate can be increased by setting the FAST bit in the DFSDM\_FLTxCr1 register. In this case, the filter does not need to be refilled by new fresh data if converting continuously from one channel because data inside the filter is valid from previously sampled continuous data. The speed increase depends on the chosen filter order. The first conversion in fast mode (FAST=1) after starting a continuous conversion by RSWSTART=1 takes still full time (as when FAST=0), then each subsequent conversion is finished in shorter intervals.

Conversion time in continuous mode:

if FAST = 0 (or first conversion if FAST=1):

for Sinc<sup>x</sup> filters:

$$t = \text{CNVCNT} / f_{\text{DFSDMCLK}} = [F_{\text{OSR}} * (I_{\text{OSR}} - 1 + F_{\text{ORD}}) + F_{\text{ORD}}] / f_{\text{CKIN}}$$

for FastSinc filter:

$$t = \text{CNVCNT} / f_{\text{DFSDMCLK}} = [F_{\text{OSR}} * (I_{\text{OSR}} - 1 + 4) + 2] / f_{\text{CKIN}}$$

if FAST = 1 (except first conversion):

for Sinc<sup>x</sup> and FastSinc filters:

$$t = \text{CNVCNT} / f_{\text{DFSDMCLK}} = [F_{\text{OSR}} * I_{\text{OSR}}] / f_{\text{CKIN}}$$

in case  $F_{\text{OSR}} = \text{FOSR}[9:0] + 1 = 1$  (filter bypassed, only integrator active):

$$t = I_{\text{OSR}} / f_{\text{CKIN}} \text{ (... but CNVCNT=0)}$$

Continuous mode is not available for injected conversions. Injected conversions can be started by timer trigger to emulate the continuous mode with precise timing.

If a regular continuous conversion is in progress (RCONT=1) and if a write access to DFSDM\_FLTxCr1 register requesting regular continuous conversion (RCONT=1) is performed, then regular continuous conversion is restarted from the next conversion cycle (like new regular continuous conversion is applied for new channel selection - even if there is no change in DFSDM\_FLTxCr1 register).

## 24.4.17 Request precedence

An injected conversion has a higher precedence than a regular conversion. A regular conversion which is already in progress is immediately interrupted by the request of an injected conversion; this regular conversion is restarted after the injected conversion finishes.

An injected conversion cannot be launched if another injected conversion is pending or already in progress: any request to launch an injected conversion (either by JSWSTART or by a trigger) is ignored as long as bit JCIP is '1' (in the DFSDM\_FLTxISR register).

Similarly, a regular conversion cannot be launched if another regular conversion is pending or already in progress: any request to launch a regular conversion (using RSWSTART) is ignored as long as bit RCIP is '1' (in the DFSDM\_FLTxISR register).

However, if an injected conversion is requested while a regular conversion is already in progress, the regular conversion is immediately stopped and an injected conversion is launched. The regular conversion is then restarted and this delayed restart is signaled in bit RPEND.

Injected conversions have precedence over regular conversions in that a injected conversion can temporarily interrupt a sequence of continuous regular conversions. When the sequence of injected conversions finishes, the continuous regular conversions start again if RCONT is still set (and RPEND bit will signalize the delayed start on the first regular conversion result).

Precedence also matters when actions are initiated by the same write to DFSDM, or if multiple actions are pending at the end of another action. For example, suppose that, while an injected conversion is in process (JCIP=1), a single write operation to DFSDM\_FLTxCr1 writes '1' to RSWSTART, requesting a regular conversion. When the injected sequence finishes, the precedence dictates that the regular conversion is performed next and its delayed start is signaled in RPEND bit.

#### 24.4.18 Power optimization in run mode

In order to reduce the consumption, the DFSDM filter and integrator are automatically put into idle when not used by conversions (RCIP=0, JCIP=0).

### 24.5 DFSDM interrupts

In order to increase the CPU performance, a set of interrupts related to the CPU event occurrence has been implemented:

- End of injected conversion interrupt:
  - enabled by JEOCIE bit in DFSDM\_FLTxCr2 register
  - indicated in JEOCF bit in DFSDM\_FLTxISR register
  - cleared by reading DFSDM\_FLTxJDATAR register (injected data)
  - indication of which channel end of conversion occurred, reported in JDATACh[2:0] bits in DFSDM\_FLTxJDATAR register
- End of regular conversion interrupt:
  - enabled by REOCIE bit in DFSDM\_FLTxCr2 register
  - indicated in REOCF bit in DFSDM\_FLTxISR register
  - cleared by reading DFSDM\_FLTxRDATAR register (regular data)
  - indication of which channel end of conversion occurred, reported in RDATACh[2:0] bits in DFSDM\_FLTxRDATAR register<sup>(a)</sup>
- Data overrun interrupt for injected conversions:
  - occurred when injected converted data were not read from DFSDM\_FLTxJDATAR register (by CPU or DMA) and were overwritten by a new injected conversion
  - enabled by JOVRIE bit in DFSDM\_FLTxCr2 register
  - indicated in JOVRF bit in DFSDM\_FLTxISR register
  - cleared by writing '1' into CLRJOVRF bit in DFSDM\_FLTxICR register

a. Availability of the input from internal ADC is device dependent, see [Table 155: DFSDM1 implementation](#).

- Data overrun interrupt for regular conversions:
  - occurred when regular converted data were not read from DFSDM\_FLTxRDATAR register (by CPU or DMA) and were overwritten by a new regular conversion
  - enabled by ROVRIE bit in DFSDM\_FLTxCR2 register
  - indicated in ROVRF bit in DFSDM\_FLTxISR register
  - cleared by writing '1' into CLRROVRF bit in DFSDM\_FLTxICR register
- Analog watchdog interrupt:
  - occurred when converted data (output data or data from analog watchdog filter - according to AWFSEL bit setting in DFSDM\_FLTxCR1 register) crosses over/under high/low thresholds in DFSDM\_FLTxAWHTR / DFSDM\_FLTxAWLTR registers
  - enabled by AWDIE bit in DFSDM\_FLTxCR2 register (on selected channels AWDCH[7:0])
  - indicated in AWDF bit in DFSDM\_FLTxISR register
  - separate indication of high or low analog watchdog threshold error by AWHTF[7:0] and AWLTF[7:0] fields in DFSDM\_FLTxAWSR register
  - cleared by writing '1' into corresponding CLRAWHTF[7:0] or CLRAWLTF[7:0] bits in DFSDM\_FLTxAWCFR register
- Short-circuit detector interrupt:
  - occurred when the number of stable data crosses over thresholds in DFSDM\_CHyAWSCDR register
  - enabled by SCDIE bit in DFSDM\_FLTxCR2 register (on channel selected by SCDEN bit in DFSDM\_CHyCFGR1 register)
  - indicated in SCDF[7:0] bits in DFSDM\_FLTxISR register (which also reports the channel on which the short-circuit detector event occurred)
  - cleared by writing '1' into the corresponding CLRSCDF[7:0] bit in DFSDM\_FLTxICR register
- Channel clock absence interrupt:
  - occurred when there is clock absence on CKINy pin (see [Clock absence detection](#) in [Section 24.4.4: Serial channel transceivers](#))
  - enabled by CKABIE bit in DFSDM\_FLTxCR2 register (on channels selected by CKABEN bit in DFSDM\_CHyCFGR1 register)
  - indicated in CKABF[y] bit in DFSDM\_FLTxISR register
  - cleared by writing '1' into CLRCKABF[y] bit in DFSDM\_FLTxICR register

**Table 162. DFSDM interrupt requests**

| Interrupt event            | Event flag | Event/Interrupt clearing method | Interrupt enable control bit |
|----------------------------|------------|---------------------------------|------------------------------|
| End of injected conversion | JEOPF      | reading DFSDM_FLTxJDATAR        | JEOCIE                       |
| End of regular conversion  | REOPF      | reading DFSDM_FLTxRDATAR        | REOCIE                       |
| Injected data overrun      | JOVRF      | writing CLRJOVRF = 1            | JOVRIE                       |
| Regular data overrun       | ROVRF      | writing CLRROVRF = 1            | ROVRIE                       |

Table 162. DFSDM interrupt requests (continued)

| Interrupt event        | Event flag                         | Event/Interrupt clearing method                        | Interrupt enable control bit |
|------------------------|------------------------------------|--------------------------------------------------------|------------------------------|
| Analog watchdog        | AWDF,<br>AWHTF[7:0],<br>AWLTF[7:0] | writing CLRAWHTF[7:0] = 1<br>writing CLRAWLTF[7:0] = 1 | AWDIE,<br>(AWDCH[7:0])       |
| short-circuit detector | SCDF[7:0]                          | writing CLRSCDF[7:0] = 1                               | SCDIE,<br>(SCDEN)            |
| Channel clock absence  | CKABF[7:0]                         | writing CLRCKABF[7:0] = 1                              | CKABIE,<br>(CKABEN)          |

## 24.6 DFSDM DMA transfer

To decrease the CPU intervention, conversions can be transferred into memory using a DMA transfer. A DMA transfer for injected conversions is enabled by setting bit JDMAEN=1 in DFSDM\_FLTxCr1 register. A DMA transfer for regular conversions is enabled by setting bit RDMAEN=1 in DFSDM\_FLTxCr1 register.

*Note:* With a DMA transfer, the interrupt flag is automatically cleared at the end of the injected or regular conversion (JEOCF or REOCF bit in DFSDM\_FLTxISR register) because DMA is reading DFSDM\_FLTxJDATAR or DFSDM\_FLTxRDATAR register.

## 24.7 DFSDM channel y registers (y=0..7)

Word access (32-bit) must be used for registers write access except DFSDM\_CHyDATINR register. Write access to DFSDM\_CHyDATINR register can be either word access (32-bit) or half-word access (16-bit).

### 24.7.1 DFSDM channel y configuration register (DFSDM\_CHyCFGR1)

This register specifies the parameters used by channel y.

Address offset: 0x00 + 0x20 \* y, (y = 0 to 7)

Reset value: 0x0000 0000

|              |              |             |      |      |      |      |             |               |            |       |      |               |    |           |    |
|--------------|--------------|-------------|------|------|------|------|-------------|---------------|------------|-------|------|---------------|----|-----------|----|
| 31           | 30           | 29          | 28   | 27   | 26   | 25   | 24          | 23            | 22         | 21    | 20   | 19            | 18 | 17        | 16 |
| DFSDM<br>EN  | CKOUT<br>SRC | Res.        | Res. | Res. | Res. | Res. | Res.        | CKOUTDIV[7:0] |            |       |      |               |    |           |    |
| rw           | rw           |             |      |      |      |      |             | rw            | rw         | rw    | rw   | rw            | rw | rw        | rw |
| 15           | 14           | 13          | 12   | 11   | 10   | 9    | 8           | 7             | 6          | 5     | 4    | 3             | 2  | 1         | 0  |
| DATPACK[1:0] |              | DATMPX[1:0] |      | Res. | Res. | Res. | CHIN<br>SEL | CHEN          | CKAB<br>EN | SCDEN | Res. | SPICKSEL[1:0] |    | SITP[1:0] |    |
| rw           | rw           | rw          | rw   |      |      |      | rw          | rw            | rw         | rw    |      | rw            | rw | rw        | rw |

Bit 31 **DFSDMEN**: Global enable for DFSDM interface

0: DFSDM interface disabled

1: DFSDM interface enabled

If DFSDM interface is enabled, then it is started to operate according to enabled y channels and enabled x filters settings (CHEN bit in DFSDM\_CHyCFGR1 and DFEN bit in DFSDM\_FLTxCR1).

Data cleared by setting DFSDMEN=0:

–all registers DFSDM\_FLTxISR are set to reset state (x = 0..3)

–all registers DFSDM\_FLTxAWSR are set to reset state (x = 0..3)

*Note: DFSDMEN is present only in DFSDM\_CH0CFGR1 register (channel y=0)*

Bit 30 **CKOUTSRC**: Output serial clock source selection

0: Source for output clock is from system clock

1: Source for output clock is from audio clock

–SAI1 clock selected by SAI1SEL[1:0] field in RCC configuration (see [Section 6.4.28: Peripherals independent clock configuration register \(RCC\\_CCIPR\)](#))

This value can be modified only when DFSDMEN=0 (in DFSDM\_CH0CFGR1 register).

*Note: CKOUTSRC is present only in DFSDM\_CH0CFGR1 register (channel y=0)*

Bits 29:24 Reserved, must be kept at reset value.

Bits 23:16 **CKOUTDIV[7:0]**: Output serial clock divider

0: Output clock generation is disabled (CKOUT signal is set to low state)

1- 255: Defines the division of system clock for the serial clock output for CKOUT signal in range 2 - 256 (Divider = CKOUTDIV+1).

CKOUTDIV also defines the threshold for a clock absence detection.

This value can only be modified when DFSDMEN=0 (in DFSDM\_CH0CFGR1 register).

If DFSDMEN=0 (in DFSDM\_CH0CFGR1 register) then CKOUT signal is set to low state (setting is performed one DFSDM clock cycle after DFSDMEN=0).

*Note: CKOUTDIV is present only in DFSDM\_CH0CFGR1 register (channel y=0)*

Bits 15:14 **DATPACK[1:0]**: Data packing mode in DFSDM\_CHyDATINR register.

0: Standard: input data in DFSDM\_CHyDATINR register are stored only in INDAT0[15:0]. To empty DFSDM\_CHyDATINR register one sample must be read by the DFSDM filter from channel y.

1: Interleaved: input data in DFSDM\_CHyDATINR register are stored as two samples:

–first sample in INDAT0[15:0] (assigned to channel y)

–second sample INDAT1[15:0] (assigned to channel y)

To empty DFSDM\_CHyDATINR register, two samples must be read by the digital filter from channel y (INDAT0[15:0] part is read as first sample and then INDAT1[15:0] part is read as next sample).

2: Dual: input data in DFSDM\_CHyDATINR register are stored as two samples:

–first sample INDAT0[15:0] (assigned to channel y)

–second sample INDAT1[15:0] (assigned to channel y+1)

To empty DFSDM\_CHyDATINR register first sample must be read by the digital filter from channel y and second sample must be read by another digital filter from channel y+1. Dual mode is available only on even channel numbers (y = 0, 2, 4, 6), for odd channel numbers (y = 1, 3, 5, 7) DFSDM\_CHyDATINR is write protected. If an even channel is set to dual mode then the following odd channel must be set into standard mode (DATPACK[1:0]=0) for correct cooperation with even channel.

3: Reserved

This value can be modified only when CHEN=0 (in DFSDM\_CHyCFGR1 register).

Bits 13:12 **DATMPX[1:0]**: Input data multiplexer for channel y

- 0: Data to channel y are taken from external serial inputs as 1-bit values. DFSDM\_CHyDATINR register is write protected.
  - 1: Data to channel y are taken from internal analog to digital converter ADC<sub>y+1</sub> output register update as 16-bit values (if ADC<sub>y+1</sub> is available). Data from ADCs are written into INDAT0[15:0] part of DFSDM\_CHyDATINR register.
  - 2: Data to channel y are taken from internal DFSDM\_CHyDATINR register by direct CPU/DMA write. There can be written one or two 16-bit data samples according DATPACK[1:0] bit field setting.
  - 3: Reserved
- This value can be modified only when CHEN=0 (in DFSDM\_CHyCFGR1 register).

*Note: DATMPX[1:0] = 1 is reserved for STM32L47x/L48x devices.*

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **CHINSEL**: Channel inputs selection

- 0: Channel inputs are taken from pins of the same channel y.
  - 1: Channel inputs are taken from pins of the following channel (channel (y+1) modulo 8).
- This value can be modified only when CHEN=0 (in DFSDM\_CHyCFGR1 register).

Bit 7 **CHEN**: Channel y enable

- 0: Channel y disabled
  - 1: Channel y enabled
- If channel y is enabled, then serial data receiving is started according to the given channel setting.

Bit 6 **CKABEN**: Clock absence detector enable on channel y

- 0: Clock absence detector disabled on channel y
- 1: Clock absence detector enabled on channel y

Bit 5 **SCDEN**: Short-circuit detector enable on channel y

- 0: Input channel y will not be guarded by the short-circuit detector
- 1: Input channel y will be continuously guarded by the short-circuit detector

Bit 4 Reserved, must be kept at reset value.

Bits 3:2 **SPICKSEL[1:0]**: SPI clock select for channel y

- 0: clock coming from external CKINy input - sampling point according SITP[1:0]
- 1: clock coming from internal CKOUT output - sampling point according SITP[1:0]
- 2: clock coming from internal CKOUT - sampling point on each second CKOUT falling edge.  
For connection to external  $\Sigma\Delta$  modulator which divides its clock input (from CKOUT) by 2 to generate its output serial communication clock (and this output clock change is active on each clock input rising edge).
- 3: clock coming from internal CKOUT output - sampling point on each second CKOUT rising edge.  
For connection to external  $\Sigma\Delta$  modulator which divides its clock input (from CKOUT) by 2 to generate its output serial communication clock (and this output clock change is active on each clock input falling edge).

This value can be modified only when CHEN=0 (in DFSDM\_CHyCFGR1 register).

Bits 1:0 **SITP[1:0]**: Serial interface type for channel y

- 00: SPI with rising edge to strobe data
  - 01: SPI with falling edge to strobe data
  - 10: Manchester coded input on DATINy pin: rising edge = logic 0, falling edge = logic 1
  - 11: Manchester coded input on DATINy pin: rising edge = logic 1, falling edge = logic 0
- This value can only be modified when CHEN=0 (in DFSDM\_CHyCFGR1 register).

### 24.7.2 DFSDM channel y configuration register (DFSDM\_CHyCFGR2)

This register specifies the parameters used by channel y.

Address offset:  $0x04 + 0x20 * y$ , ( $y = 0$  to  $7$ )

Reset value:  $0x0000\ 0000$

|              |    |    |    |    |    |    |    |            |    |    |    |      |      |      |    |
|--------------|----|----|----|----|----|----|----|------------|----|----|----|------|------|------|----|
| 31           | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23         | 22 | 21 | 20 | 19   | 18   | 17   | 16 |
| OFFSET[23:8] |    |    |    |    |    |    |    |            |    |    |    |      |      |      |    |
| rW           | rW | rW | rW | rW | rW | rW | rW | rW         | rW | rW | rW | rW   | rW   | rW   | rW |
| 15           | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7          | 6  | 5  | 4  | 3    | 2    | 1    | 0  |
| OFFSET[7:0]  |    |    |    |    |    |    |    | DTRBS[4:0] |    |    |    | Res. | Res. | Res. |    |
| rW           | rW | rW | rW | rW | rW | rW | rW | rW         | rW | rW | rW | rW   |      |      |    |

Bits 31:8 **OFFSET[23:0]**: 24-bit calibration offset for channel y

For channel y, OFFSET is applied to the results of each conversion from this channel.  
This value is set by software.

Bits 7:3 **DTRBS[4:0]**: Data right bit-shift for channel y

0-31: Defines the shift of the data result coming from the integrator - how many bit shifts to the right will be performed to have final results. Bit-shift is performed before offset correction. The data shift is rounding the result to nearest integer value. The sign of shifted result is maintained (to have valid 24-bit signed format of result data).

This value can be modified only when CHEN=0 (in DFSDM\_CHyCFGR1 register).

Bits 2:0 Reserved, must be kept at reset value.

### 24.7.3 DFSDM channel y analog watchdog and short-circuit detector register (DFSDM\_CHyAWSCDR)

Short-circuit detector and analog watchdog settings for channel y.

Address offset:  $0x08 + 0x20 * y$ , ( $y = 0$  to  $7$ )

Reset value:  $0x0000\ 0000$

|            |      |      |      |      |      |      |      |             |    |      |             |    |    |    |    |
|------------|------|------|------|------|------|------|------|-------------|----|------|-------------|----|----|----|----|
| 31         | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23          | 22 | 21   | 20          | 19 | 18 | 17 | 16 |
| Res.       | Res. | Res. | Res. | Res. | Res. | Res. | Res. | AWFORD[1:0] |    | Res. | AWFOSR[4:0] |    |    |    |    |
|            |      |      |      |      |      |      |      | rW          | rW |      | rW          | rW | rW | rW | rW |
| 15         | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7           | 6  | 5    | 4           | 3  | 2  | 1  | 0  |
| BKSCD[3:0] |      |      |      | Res. | Res. | Res. | Res. | SCDT[7:0]   |    |      |             |    |    |    |    |
| rW         | rW   | rW   | rW   |      |      |      |      | rW          | rW | rW   | rW          | rW | rW | rW | rW |

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:22 **AWFORD[1:0]**: Analog watchdog Sinc filter order on channel y

0: FastSinc filter type

1: Sinc<sup>1</sup> filter type

2: Sinc<sup>2</sup> filter type

3: Sinc<sup>3</sup> filter type

Sinc<sup>x</sup> filter type transfer function:

$$H(z) = \left( \frac{1 - z^{-FOSR}}{1 - z^{-1}} \right)^x$$

FastSinc filter type transfer function: 
$$H(z) = \left( \frac{1 - z^{-FOSR}}{1 - z^{-1}} \right)^2 \cdot (1 + z^{-(2 \cdot FOSR)})$$

This bit can be modified only when CHEN=0 (in DFSDM\_CHyCFGR1 register).

Bit 21 Reserved, must be kept at reset value.

Bits 20:16 **AWFOSR[4:0]**: Analog watchdog filter oversampling ratio (decimation rate) on channel y

0 - 31: Defines the length of the Sinc type filter in the range 1 - 32 (AWFOSR + 1). This number is also the decimation ratio of the analog data rate.

This bit can be modified only when CHEN=0 (in DFSDM\_CHyCFGR1 register).

*Note: If AWFOSR = 0 then the filter has no effect (filter bypass).*

Bits 15:12 **BKSCD[3:0]**: Break signal assignment for short-circuit detector on channel y

BKSCD[i] = 0: Break i signal not assigned to short-circuit detector on channel y

BKSCD[i] = 1: Break i signal assigned to short-circuit detector on channel y

Bits 11:8 Reserved, must be kept at reset value.

Bits 7:0 **SCDT[7:0]**: short-circuit detector threshold for channel y

These bits are written by software to define the threshold counter for the short-circuit detector. If this value is reached, then a short-circuit detector event occurs on a given channel.

#### 24.7.4 DFSDM channel y watchdog filter data register (DFSDM\_CHyWDATR)

This register contains the data resulting from the analog watchdog filter associated to the input channel y.

Address offset: 0x0C + 0x20 \* y, (y = 0 to 7)

Reset value: 0x0000 0000

|             |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|-------------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| 31          | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Res.        | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. |
|             |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| 15          | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| WDATA[15:0] |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| r           | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **WDATA[15:0]**: Input channel y watchdog data  
Data converted by the analog watchdog filter for input channel y. This data is continuously converted (no trigger) for this channel, with a limited resolution (OSR=1..32/sinc order = 1..3).

24.7.5 DFSDM channel y data input register (DFSDM\_CHyDATINR)

This register contains 16-bit input data to be processed by DFSDM filter module. Write access can be either word access (32-bit) or half-word access (16-bit).

Address offset: 0x10 + 0x20 \* y, (y = 0 to 7)

Reset value: 0x0000 0000

|              |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|--------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31           | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| INDAT1[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW           | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |
| 15           | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |

|              |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|--------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| INDAT0[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW           | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 31:16 **INDAT1[15:0]**: Input data for channel y or channel y+1

Input parallel channel data to be processed by the digital filter if DATMPX[1:0]=1 or DATMPX[1:0]=2. Data can be written by CPU/DMA (if DATMPX[1:0]=2) or directly by internal ADC<sup>(1)</sup> (if DATMPX[1:0]=1).

If DATPACK[1:0]=0 (standard mode)

INDAT0[15:0] is write protected (not used for input sample).

If DATPACK[1:0]=1 (interleaved mode)

Second channel y data sample is stored into INDAT1[15:0]. First channel y data sample is stored into INDAT0[15:0]. Both samples are read sequentially by DFSDM\_FLTx filter as two channel y data samples.

If DATPACK[1:0]=2 (dual mode).

For even y channels: sample in INDAT1[15:0] is automatically copied into INDAT0[15:0] of channel (y+1).

For odd y channels: INDAT1[15:0] is write protected.

See [Section 24.4.6: Parallel data inputs](#) for more details.

INDAT0[15:1] is in the 16-bit signed format.

Bits 15:0 **INDAT0[15:0]**: Input data for channel y

Input parallel channel data to be processed by the digital filter if DATMPX[1:0]=1 or DATMPX[1:0]=2. Data can be written by CPU/DMA (if DATMPX[1:0]=2) or directly by internal ADC<sup>(1)</sup> (if DATMPX[1:0]=1).

If DATPACK[1:0]=0 (standard mode)

Channel y data sample is stored into INDAT0[15:0].

If DATPACK[1:0]=1 (interleaved mode)

First channel y data sample is stored into INDAT0[15:0]. Second channel y data sample is stored into INDAT1[15:0]. Both samples are read sequentially by DFSDM\_FLTx filter as two channel y data samples.

If DATPACK[1:0]=2 (dual mode).

For even y channels: Channel y data sample is stored into INDAT0[15:0].

For odd y channels: INDAT0[15:0] is write protected.

See [Section 24.4.6: Parallel data inputs](#) for more details.

INDAT0[15:0] is in the 16-bit signed format.

1. Availability of the input from internal ADC is device dependent, see [Table 155: DFSDM1 implementation](#).

## 24.8 DFSDM filter x module registers (x=0..3)

Word access (32-bit) must be used for registers write access except DFSDM\_CHyDATINR register.

### 24.8.1 DFSDM filter x control register 1 (DFSDM\_FLTxCR1)

Address offset:  $0x100 + 0x80 * x$ , ( $x = 0$  to  $3$ )

Reset value: 0x0000 0000

|      |             |      |      |      |              |    |    |      |      |        |       |       |       |          |      |
|------|-------------|------|------|------|--------------|----|----|------|------|--------|-------|-------|-------|----------|------|
| 31   | 30          | 29   | 28   | 27   | 26           | 25 | 24 | 23   | 22   | 21     | 20    | 19    | 18    | 17       | 16   |
| Res. | AWFSEL      | FAST | Res. | Res. | RCH[2:0]     |    |    | Res. | Res. | RDMAEN | Res.  | RSYNC | RCONT | RSWSTART | Res. |
|      | rw          | rw   |      |      | rw           | rw | rw |      |      | rw     |       | rw    | rw    | rt_w1    |      |
| 15   | 14          | 13   | 12   | 11   | 10           | 9  | 8  | 7    | 6    | 5      | 4     | 3     | 2     | 1        | 0    |
| Res. | JEXTEN[1:0] |      | Res. | Res. | JEXTSEL[2:0] |    |    | Res. | Res. | JDMAEN | JSCAN | JSYNC | Res.  | JSWSTART | DFEN |
|      | rw          | rw   |      |      | rw           | rw | rw |      |      | rw     | rw    | rw    |       | rt_w1    | rw   |

Bit 31 Reserved, must be kept at reset value.

Bit 30 **AWFSEL**: Analog watchdog fast mode select

0: Analog watchdog on data output value (after the digital filter). The comparison is done after offset correction and shift

1: Analog watchdog on channel transceivers value (after watchdog filter)

Bit 29 **FAST**: Fast conversion mode selection for regular conversions

0: Fast conversion mode disabled

1: Fast conversion mode enabled

When converting a regular conversion in continuous mode, having enabled the fast mode causes each conversion (except the first) to execute faster than in standard mode. This bit has no effect on conversions which are not continuous.

This bit can be modified only when DFEN=0 (DFSDM\_FLTxCR1).

if FAST=0 (or first conversion in continuous mode if FAST=1):

$$t = [F_{OSR} * (I_{OSR}-1 + F_{ORD}) + F_{ORD}] / f_{CKIN} \dots \text{for Sinc}^x \text{ filters}$$

$$t = [F_{OSR} * (I_{OSR}-1 + 4) + 2] / f_{CKIN} \dots \text{for FastSinc filter}$$

if FAST=1 in continuous mode (except first conversion):

$$t = [F_{OSR} * I_{OSR}] / f_{CKIN}$$

in case if  $F_{OSR} = F_{OSR}[9:0] + 1 = 1$  (filter bypassed, active only integrator):

$$t = I_{OSR} / f_{CKIN} \dots \text{but CNVCNT}=0$$

where:  $f_{CKIN}$  is the channel input clock frequency (on given channel CKINy pin) or input data rate in case of parallel data input.

Bits 28:27 Reserved, must be kept at reset value.

Bits 26:24 **RCH[2:0]**: Regular channel selection

0: Channel 0 is selected as the regular channel

1: Channel 1 is selected as the regular channel

...

7: Channel 7 is selected as the regular channel

Writing these bits when RCIP=1 takes effect when the next regular conversion begins. This is especially useful in continuous mode (when RCONT=1). It also affects regular conversions which are pending (due to ongoing injected conversion).

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **RDMAEN**: DMA channel enabled to read data for the regular conversion

0: The DMA channel is not enabled to read regular data

1: The DMA channel is enabled to read regular data

This bit can be modified only when DFEN=0 (DFSDM\_FLTxCR1).

Bit 20 Reserved, must be kept at reset value.

Bit 19 **RSYNC**: Launch regular conversion synchronously with DFSDM\_FLT0

0: Do not launch a regular conversion synchronously with DFSDM\_FLT0

1: Launch a regular conversion in this DFSDM\_FLTx at the very moment when a regular conversion is launched in DFSDM\_FLT0

This bit can be modified only when DFEN=0 (DFSDM\_FLTxCR1).

Bit 18 **RCONT**: Continuous mode selection for regular conversions

0: The regular channel is converted just once for each conversion request

1: The regular channel is converted repeatedly after each conversion request

Writing '0' to this bit while a continuous regular conversion is already in progress stops the continuous mode immediately.

Bit 17 **RSWSTART**: Software start of a conversion on the regular channel

0: Writing '0' has no effect

1: Writing '1' makes a request to start a conversion on the regular channel and causes RCIP to become '1'. If RCIP=1 already, writing to RSWSTART has no effect. Writing '1' has no effect if RSYNC=1.

This bit is always read as '0'.

Bits 16:15 Reserved, must be kept at reset value.

Bits 14:13 **JEXTEN[1:0]**: Trigger enable and trigger edge selection for injected conversions

00: Trigger detection is disabled

01: Each rising edge on the selected trigger makes a request to launch an injected conversion

10: Each falling edge on the selected trigger makes a request to launch an injected conversion

11: Both rising edges and falling edges on the selected trigger make requests to launch injected conversions

This bit can be modified only when DFEN=0 (DFSDM\_FLTxCR1).

Bits 12:11 Reserved, must be kept at reset value.

Bits 10:8 **JEXTSEL[2:0]**: Trigger signal selection for launching injected conversions

0x0-0x7: Trigger inputs selected by the following table.

This bit can be modified only when DFEN=0 (DFSDM\_FLTxCR1).

|      | DFSDM_FLT0   | DFSDM_FLT1   | DFSDM_FLT2   | DFSDM_FLT3   |
|------|--------------|--------------|--------------|--------------|
| 0x00 | dfsdm_jtrg0  | dfsdm_jtrg0  | dfsdm_jtrg0  | dfsdm_jtrg0  |
| 0x01 | dfsdm_jtrg1  | dfsdm_jtrg1  | dfsdm_jtrg1  | dfsdm_jtrg1  |
| 0x02 | dfsdm_jtrg2  | dfsdm_jtrg2  | dfsdm_jtrg2  | dfsdm_jtrg2  |
| 0x03 | dfsdm_jtrg3  | dfsdm_jtrg3  | dfsdm_jtrg3  | dfsdm_jtrg4  |
| 0x04 | dfsdm_jtrg5  | dfsdm_jtrg5  | dfsdm_jtrg5  | dfsdm_jtrg6  |
| 0x05 | dfsdm_jtrg7  | dfsdm_jtrg7  | dfsdm_jtrg8  | dfsdm_jtrg8  |
| 0x06 | dfsdm_jtrg9  | dfsdm_jtrg9  | dfsdm_jtrg9  | dfsdm_jtrg9  |
| 0x07 | dfsdm_jtrg10 | dfsdm_jtrg10 | dfsdm_jtrg10 | dfsdm_jtrg10 |

Refer to [Table 158: DFSDM triggers connection](#).

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **JDMAEN**: DMA channel enabled to read data for the injected channel group

0: The DMA channel is not enabled to read injected data

1: The DMA channel is enabled to read injected data

This bit can be modified only when DFEN=0 (DFSDM\_FLTxCR1).

Bit 4 **JSCAN**: Scanning conversion mode for injected conversions

0: One channel conversion is performed from the injected channel group and next the selected channel from this group is selected.

1: The series of conversions for the injected group channels is executed, starting over with the lowest selected channel.

This bit can be modified only when DFEN=0 (DFSDM\_FLTxCR1).

Writing JCHG if JSCAN=0 resets the channel selection to the lowest selected channel.

Bit 3 **JSYNC**: Launch an injected conversion synchronously with the DFSDM\_FLT0 JSWSTART trigger

0: Do not launch an injected conversion synchronously with DFSDM\_FLT0

1: Launch an injected conversion in this DFSDM\_FLTx at the very moment when an injected conversion is launched in DFSDM\_FLT0 by its JSWSTART trigger

This bit can be modified only when DFEN=0 (DFSDM\_FLTxCR1).

Bit 2 Reserved, must be kept at reset value.

Bit 1 **JSWSTART**: Start a conversion of the injected group of channels

0: Writing '0' has no effect.

1: Writing '1' makes a request to convert the channels in the injected conversion group, causing JCIP to become '1' at the same time. If JCIP=1 already, then writing to JSWSTART has no effect. Writing '1' has no effect if JSYNC=1.

This bit is always read as '0'.

Bit 0 **DFEN**: DFSDM\_FLTx enable

0: DFSDM\_FLTx is disabled. All conversions of given DFSDM\_FLTx are stopped immediately and all DFSDM\_FLTx functions are stopped.

1: DFSDM\_FLTx is enabled. If DFSDM\_FLTx is enabled, then DFSDM\_FLTx starts operating according to its setting.

Data which are cleared by setting DFEN=0:

–register DFSDM\_FLTxISR is set to the reset state

–register DFSDM\_FLTxAWSR is set to the reset state

## 24.8.2 DFSDM filter x control register 2 (DFSDM\_FLTxCR2)

Address offset:  $0x104 + 0x80 * x$ , ( $x = 0$  to  $3$ )

Reset value: 0x0000 0000

|           |      |      |      |      |      |      |      |            |            |       |       |            |            |            |            |

| 31        | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23         | 22         | 21    | 20    | 19         | 18         | 17         | 16         |
| Res.      | Res. | Res. | Res. | Res. | Res. | Res. | Res. | AWDCH[7:0] |            |       |       |            |            |            |            |
|           |      |      |      |      |      |      |      | r/w        | r/w        | r/w   | r/w   | r/w        | r/w        | r/w        | r/w        |
| 15        | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7          | 6          | 5     | 4     | 3          | 2          | 1          | 0          |
| EXCH[7:0] |      |      |      |      |      |      |      | Res.       | CKAB<br>IE | SCDIE | AWDIE | ROVR<br>IE | JOVRI<br>E | REOC<br>IE | JEOCI<br>E |
| r/w       | r/w  | r/w  | r/w  | r/w  | r/w  | r/w  | r/w  |            | r/w        | r/w   | r/w   | r/w        | r/w        | r/w        | r/w        |

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **AWDCH[7:0]**: Analog watchdog channel selection

These bits select the input channel to be guarded continuously by the analog watchdog.

AWDCH[y] = 0: Analog watchdog is disabled on channel y

AWDCH[y] = 1: Analog watchdog is enabled on channel y

Bits 15:8 **EXCH[7:0]**: Extremes detector channel selection

These bits select the input channels to be taken by the Extremes detector.

EXCH[y] = 0: Extremes detector does not accept data from channel y

EXCH[y] = 1: Extremes detector accepts data from channel y

Bit 7 Reserved, must be kept at reset value.

Bit 6 **CKABIE**: Clock absence interrupt enable

0: Detection of channel input clock absence interrupt is disabled

1: Detection of channel input clock absence interrupt is enabled

Please see the explanation of CKABF[7:0] in DFSDM\_FLTISR.

*Note: CKABIE is present only in DFSDM\_FLT0CR2 register (filter x=0)*

Bit 5 **SCDIE**: Short-circuit detector interrupt enable

0: short-circuit detector interrupt is disabled

1: short-circuit detector interrupt is enabled

Please see the explanation of SCDF[7:0] in DFSDM\_FLTISR.

*Note: SCDIE is present only in DFSDM\_FLT0CR2 register (filter x=0)*

Bit 4 **AWDIE**: Analog watchdog interrupt enable

0: Analog watchdog interrupt is disabled

1: Analog watchdog interrupt is enabled

Please see the explanation of AWDF in DFSDM\_FLTISR.

Bit 3 **ROVRIE**: Regular data overrun interrupt enable

0: Regular data overrun interrupt is disabled

1: Regular data overrun interrupt is enabled

Please see the explanation of ROVRF in DFSDM\_FLTISR.

Bit 2 **JOVRIE**: Injected data overrun interrupt enable

0: Injected data overrun interrupt is disabled

1: Injected data overrun interrupt is enabled

Please see the explanation of JOVRF in DFSDM\_FLTISR.

Bit 1 **REOCIE**: Regular end of conversion interrupt enable

0: Regular end of conversion interrupt is disabled

1: Regular end of conversion interrupt is enabled

Please see the explanation of REOCF in DFSDM\_FLTISR.

Bit 0 **JEOCIE**: Injected end of conversion interrupt enable

0: Injected end of conversion interrupt is disabled

1: Injected end of conversion interrupt is enabled

Please see the explanation of JEOCF in DFSDM\_FLTISR.

### 24.8.3 DFSDM filter x interrupt and status register (DFSDM\_FLTxISR)

Address offset:  $0x108 + 0x80 * x$ , ( $x = 0$  to  $3$ )

Reset value: 0x00FF 0000

|           |      |      |      |      |      |      |      |            |      |      |      |       |       |       |       |
|-----------|------|------|------|------|------|------|------|------------|------|------|------|-------|-------|-------|-------|
| 31        | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23         | 22   | 21   | 20   | 19    | 18    | 17    | 16    |
| SCDF[7:0] |      |      |      |      |      |      |      | CKABF[7:0] |      |      |      |       |       |       |       |
| r         | r    | r    | r    | r    | r    | r    | r    | r          | r    | r    | r    | r     | r     | r     | r     |
| 15        | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7          | 6    | 5    | 4    | 3     | 2     | 1     | 0     |
| Res.      | RCIP | JCIP | Res. | Res. | Res. | Res. | Res. | Res.       | Res. | Res. | AWDF | ROVRF | JOVRF | REOCF | JEOCF |
|           | r    | r    |      |      |      |      |      |            |      |      | r    | r     | r     | r     | r     |

Bits 31:24 **SCDF[7:0]**: short-circuit detector flag

SDCF[y]=0: No short-circuit detector event occurred on channel y

SDCF[y]=1: The short-circuit detector counter reaches, on channel y, the value programmed in the DFSDM\_CHyAWSCDR registers

This bit is set by hardware. It can be cleared by software using the corresponding CLRSCDF[y] bit in the DFSDM\_FLTxICR register. SCDF[y] is cleared also by hardware when CHEN[y] = 0 (given channel is disabled).

*Note: SCDF[7:0] is present only in DFSDM\_FLT0ISR register (filter x=0)*

Bits 23:16 **CKABF[7:0]**: Clock absence flag

CKABF[y]=0: Clock signal on channel y is present.

CKABF[y]=1: Clock signal on channel y is not present.

Given y bit is set by hardware when clock absence is detected on channel y. It is held at CKABF[y]=1 state by hardware when CHEN=0 (see DFSDM\_CHyCFGR1 register). It is held at CKABF[y]=1 state by hardware when the transceiver is not yet synchronized. It can be cleared by software using the corresponding CLRCKABF[y] bit in the DFSDM\_FLTxICR register.

*Note: CKABF[7:0] is present only in DFSDM\_FLT0ISR register (filter x=0)*

Bit 15 Reserved, must be kept at reset value.

Bit 14 **RCIP**: Regular conversion in progress status

0: No request to convert the regular channel has been issued

1: The conversion of the regular channel is in progress or a request for a regular conversion is pending

A request to start a regular conversion is ignored when RCIP=1.

Bit 13 **JCIP**: Injected conversion in progress status

0: No request to convert the injected channel group (neither by software nor by trigger) has been issued

1: The conversion of the injected channel group is in progress or a request for a injected conversion is pending, due either to '1' being written to JSWSTART or to a trigger detection

A request to start an injected conversion is ignored when JCIP=1.

Bits 12:5 Reserved, must be kept at reset value.

Bit 4 **AWDF**: Analog watchdog

0: No Analog watchdog event occurred

1: The analog watchdog block detected voltage which crosses the value programmed in the DFSDM\_FLTxAWLTR or DFSDM\_FLTxAWHTR registers.

This bit is set by hardware. It is cleared by software by clearing all source flag bits AWHTF[7:0] and AWLTF[7:0] in DFSDM\_FLTxAWSR register (by writing '1' into the clear bits in DFSDM\_FLTxAWCFR register).

**Bit 3 ROVRF:** Regular conversion overrun flag

0: No regular conversion overrun has occurred

1: A regular conversion overrun has occurred, which means that a regular conversion finished while REOCF was already '1'. RDATAR is not affected by overruns

This bit is set by hardware. It can be cleared by software using the CLRROVRF bit in the DFSDM\_FLTxICR register.

**Bit 2 JOVRF:** Injected conversion overrun flag

0: No injected conversion overrun has occurred

1: An injected conversion overrun has occurred, which means that an injected conversion finished while JEOCF was already '1'. JDATAR is not affected by overruns

This bit is set by hardware. It can be cleared by software using the CLRJOVRF bit in the DFSDM\_FLTxICR register.

**Bit 1 REOCF:** End of regular conversion flag

0: No regular conversion has completed

1: A regular conversion has completed and its data may be read

This bit is set by hardware. It is cleared when the software or DMA reads DFSDM\_FLTxRDATAR.

**Bit 0 JEOCF:** End of injected conversion flag

0: No injected conversion has completed

1: An injected conversion has completed and its data may be read

This bit is set by hardware. It is cleared when the software or DMA reads DFSDM\_FLTxJDATAR.

**Note:** For each of the flag bits, an interrupt can be enabled by setting the corresponding bit in DFSDM\_FLTxCR2. If an interrupt is called, the flag must be cleared before exiting the interrupt service routine.

All the bits of DFSDM\_FLTxISR are automatically reset when DFEN=0.

**24.8.4 DFSDM filter x interrupt flag clear register (DFSDM\_FLTxICR)**Address offset:  $0x10C + 0x80 * x$ , ( $x = 0$  to  $3$ )

Reset value: 0x0000 0000

| 31           | 30    | 29    | 28    | 27    | 26    | 25    | 24    | 23            | 22    | 21    | 20    | 19       | 18       | 17    | 16    |
|--------------|-------|-------|-------|-------|-------|-------|-------|---------------|-------|-------|-------|----------|----------|-------|-------|
| CLRSCDF[7:0] |       |       |       |       |       |       |       | CLRCKABF[7:0] |       |       |       |          |          |       |       |

| 15           | 14    | 13    | 12    | 11    | 10    | 9     | 8     | 7             | 6     | 5     | 4     | 3        | 2        | 1     | 0     |
| Res.         | Res.  | Res.  | Res.  | Res.  | Res.  | Res.  | Res.  | Res.          | Res.  | Res.  | Res.  | CLRROVRF | CLRJOVRF | Res.  | Res.  |
|              |       |       |       |       |       |       |       |               |       |       |       | rc_w1    | rc_w1    |       |       |

Bits 31:24 **CLRSCDF[7:0]**: Clear the short-circuit detector flag

CLRSCDF[y]=0: Writing '0' has no effect

CLRSCDF[y]=1: Writing '1' to position y clears the corresponding SCDF[y] bit in the DFSDM\_FLTxISR register

*Note: CLRSCDF[7:0] is present only in DFSDM\_FLT0ICR register (filter x=0)*

Bits 23:16 **CLRCKABF[7:0]**: Clear the clock absence flag

CLRCKABF[y]=0: Writing '0' has no effect

CLRCKABF[y]=1: Writing '1' to position y clears the corresponding CKABF[y] bit in the DFSDM\_FLTxISR register. When the transceiver is not yet synchronized, the clock absence flag is set and cannot be cleared by CLRCKABF[y].

*Note: CLRCKABF[7:0] is present only in DFSDM\_FLT0ICR register (filter x=0)*

Bits 15:4 Reserved, must be kept at reset value.

Bit 3 **CLRROVRF**: Clear the regular conversion overrun flag

0: Writing '0' has no effect

1: Writing '1' clears the ROVRF bit in the DFSDM\_FLTxISR register

Bit 2 **CLRJOVRF**: Clear the injected conversion overrun flag

0: Writing '0' has no effect

1: Writing '1' clears the JOVRF bit in the DFSDM\_FLTxISR register

Bits 1:0 Reserved, must be kept at reset value.

*Note: The bits of DFSDM\_FLTxICR are always read as '0'.*

## 24.8.5 DFSDM filter x injected channel group selection register (DFSDM\_FLTxJCHGR)

Address offset:  $0x110 + 0x80 * x$ , ( $x = 0$  to  $3$ )

Reset value: 0x0000 0001

|      |      |      |      |      |      |      |      |           |      |      |      |      |      |      |      |
|------|------|------|------|------|------|------|------|-----------|------|------|------|------|------|------|------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23        | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.      | Res. | Res. | Res. | Res. | Res. | Res. | Res. |
|      |      |      |      |      |      |      |      |           |      |      |      |      |      |      |      |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7         | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | JCHG[7:0] |      |      |      |      |      |      |      |
|      |      |      |      |      |      |      |      | r/w       | r/w  | r/w  | r/w  | r/w  | r/w  | r/w  | r/w  |

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **JCHG[7:0]**: Injected channel group selection

JCHG[y]=0: channel y is not part of the injected group

JCHG[y]=1: channel y is part of the injected group

If JSCAN=1, each of the selected channels is converted, one after another. The lowest channel (channel 0, if selected) is converted first and the sequence ends at the highest selected channel.

If JSCAN=0, then only one channel is converted from the selected channels, and the channel selection is moved to the next channel. Writing JCHG, if JSCAN=0, resets the channel selection to the lowest selected channel.

At least one channel must always be selected for the injected group. Writes causing all JCHG bits to be zero are ignored.

## 24.8.6 DFSDM filter x control register (DFSDM\_FLTxFCR)

Address offset:  $0x114 + 0x80 * x$ , ( $x = 0$  to  $3$ )

Reset value:  $0x0000\ 0000$

|           |      |      |      |      |      |           |      |           |    |    |    |    |    |    |    |
|-----------|------|------|------|------|------|-----------|------|-----------|----|----|----|----|----|----|----|
| 31        | 30   | 29   | 28   | 27   | 26   | 25        | 24   | 23        | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| FORD[2:0] |      |      | Res. | Res. | Res. | FOSR[9:0] |      |           |    |    |    |    |    |    |    |
| rw        | rw   | rw   |      |      |      | rw        | rw   | rw        | rw | rw | rw | rw | rw | rw | rw |
| 15        | 14   | 13   | 12   | 11   | 10   | 9         | 8    | 7         | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| Res.      | Res. | Res. | Res. | Res. | Res. | Res.      | Res. | IOSR[7:0] |    |    |    |    |    |    |    |
|           |      |      |      |      |      |           |      | rw        | rw | rw | rw | rw | rw | rw | rw |

Bits 31:29 **FORD[2:0]**: Sinc filter order

0: FastSinc filter type

1: Sinc<sup>1</sup> filter type

2: Sinc<sup>2</sup> filter type

3: Sinc<sup>3</sup> filter type

4: Sinc<sup>4</sup> filter type

5: Sinc<sup>5</sup> filter type

6-7: Reserved

Sinc<sup>x</sup> filter type transfer function:

$$H(z) = \left( \frac{1 - z^{-FOSR}}{1 - z^{-1}} \right)^x$$

FastSinc filter type transfer function:  $H(z) = \left( \frac{1 - z^{-FOSR}}{1 - z^{-1}} \right)^2 \cdot (1 + z^{-(2 \cdot FOSR)})$

This bit can only be modified when DFEN=0 (DFSDM\_FLTxCR1).

Bits 28:26 Reserved, must be kept at reset value.

Bits 25:16 **FOSR[9:0]**: Sinc filter oversampling ratio (decimation rate)

0 - 1023: Defines the length of the Sinc type filter in the range 1 - 1024 ( $F_{OSR} = FOSR[9:0] + 1$ ). This number is also the decimation ratio of the output data rate from filter.

This bit can only be modified when DFEN=0 (DFSDM\_FLTxCR1)

*Note: If FOSR = 0, then the filter has no effect (filter bypass).*

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **IOSR[7:0]**: Integrator oversampling ratio (averaging length)

0 - 255: The length of the Integrator in the range 1 - 256 ( $IOSR + 1$ ). Defines how many samples from Sinc filter will be summed into one output data sample from the integrator. The output data rate from the integrator will be decreased by this number (additional data decimation ratio).

This bit can only be modified when DFEN=0 (DFSDM\_FLTxCR1)

*Note: If IOSR = 0, then the Integrator has no effect (Integrator bypass).*

### 24.8.7 DFSDM filter x data register for injected group (DFSDM\_FLTxJDATAR)

Address offset:  $0x118 + 0x80 * x$ , ( $x = 0$  to  $3$ )

Reset value:  $0x0000\ 0000$

|             |    |    |    |    |    |    |    |      |      |      |      |      |            |    |    |
|-------------|----|----|----|----|----|----|----|------|------|------|------|------|------------|----|----|
| 31          | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23   | 22   | 21   | 20   | 19   | 18         | 17 | 16 |
| JDATA[23:8] |    |    |    |    |    |    |    |      |      |      |      |      |            |    |    |
| r           | r  | r  | r  | r  | r  | r  | r  | r    | r    | r    | r    | r    | r          | r  | r  |
| 15          | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7    | 6    | 5    | 4    | 3    | 2          | 1  | 0  |
| JDATA[7:0]  |    |    |    |    |    |    |    | Res. | Res. | Res. | Res. | Res. | JDATA[2:0] |    |    |
| r           | r  | r  | r  | r  | r  | r  | r  |      |      |      |      |      | r          | r  | r  |

Bits 31:8 **JDATA[23:0]**: Injected group conversion data

When each conversion of a channel in the injected group finishes, its resulting data is stored in this field. The data is valid when JEOCF=1. Reading this register clears the corresponding JEOCF.

Bits 7:3 Reserved, must be kept at reset value.

Bits 2:0 **JDATA[2:0]**: Injected channel most recently converted

When each conversion of a channel in the injected group finishes, JDATA[2:0] is updated to indicate which channel was converted. Thus, JDATA[23:0] holds the data that corresponds to the channel indicated by JDATA[2:0].

**Note:** DMA may be used to read the data from this register. Half-word accesses may be used to read only the MSBs of conversion data.

Reading this register also clears JEOCF in DFSDM\_FLTxISR. Thus, the firmware must not read this register if DMA is activated to read data from this register.

### 24.8.8 DFSDM filter x data register for the regular channel (DFSDM\_FLTxRDATAR)

Address offset:  $0x11C + 0x80 * x$ , ( $x = 0$  to  $3$ )

Reset value:  $0x0000\ 0000$

|             |    |    |    |    |    |    |    |      |      |      |       |      |                           |    |    |
|-------------|----|----|----|----|----|----|----|------|------|------|-------|------|---------------------------|----|----|
| 31          | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23   | 22   | 21   | 20    | 19   | 18                        | 17 | 16 |
| RDATA[23:8] |    |    |    |    |    |    |    |      |      |      |       |      |                           |    |    |
| r           | r  | r  | r  | r  | r  | r  | r  | r    | r    | r    | r     | r    | r                         | r  | r  |
| 15          | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7    | 6    | 5    | 4     | 3    | 2                         | 1  | 0  |
| RDATA[7:0]  |    |    |    |    |    |    |    | Res. | Res. | Res. | RPEND | Res. | RDATA[2:0] <sup>(1)</sup> |    |    |
| r           | r  | r  | r  | r  | r  | r  | r  |      |      |      | r     |      | r                         | r  | r  |

1. Availability of the input from internal ADC is device dependent, see [Table 155: DFSDM1 implementation](#).

Bits 31:8 **RDATA[23:0]**: Regular channel conversion data

When each regular conversion finishes, its data is stored in this register. The data is valid when REOCF=1. Reading this register clears the corresponding REOCF.

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **RPEND**: Regular channel pending data

Regular data in RDATA[23:0] was delayed due to an injected channel trigger during the conversion

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **RDATA[2:0]**<sup>(1)</sup>: Regular channel most recently converted

When each regular conversion finishes, RDATA[2:0] is updated to indicate which channel was converted (because regular channel selection RCH[2:0] in DFSDM\_FLTxCr1 register can be updated during regular conversion). Thus RDATA[23:0] holds the data that corresponds to the channel indicated by RDATA[2:0].

1. Availability of the input from internal ADC is device dependent, see [Table 155: DFSDM1 implementation](#).

**Note:** *Half-word accesses may be used to read only the MSBs of conversion data.*

*Reading this register also clears REOCF in DFSDM\_FLTxISR.*

### 24.8.9 DFSDM filter x analog watchdog high threshold register (DFSDM\_FLTxAWHTR)

Address offset:  $0x120 + 0x80 * x$ , ( $x = 0$  to  $3$ )

Reset value: 0x0000 0000

|            |    |    |    |    |    |    |    |      |      |      |      |            |    |    |    |
|------------|----|----|----|----|----|----|----|------|------|------|------|------------|----|----|----|
| 31         | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23   | 22   | 21   | 20   | 19         | 18 | 17 | 16 |
| AWHT[23:8] |    |    |    |    |    |    |    |      |      |      |      |            |    |    |    |

Bits 31:8 **AWHT[23:0]**: Analog watchdog high threshold

These bits are written by software to define the high threshold for the analog watchdog.

**Note:** *In case channel transceivers monitor (AWFSEL=1), the higher 16 bits (AWHT[23:8]) define the 16-bit threshold as compared with the analog watchdog filter output (because data coming from the analog watchdog filter are up to a 16-bit resolution). Bits AWHT[7:0] are not taken into comparison in this case.*

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 **BKAWH[3:0]**: Break signal assignment to analog watchdog high threshold event

BKAWH[i] = 0: Break i signal is not assigned to an analog watchdog high threshold event

BKAWH[i] = 1: Break i signal is assigned to an analog watchdog high threshold event

### 24.8.10 DFSDM filter x analog watchdog low threshold register (DFSDM\_FLTxAWLTR)

Address offset:  $0x124 + 0x80 * x$ , ( $x = 0$  to  $3$ )

Reset value:  $0x0000\ 0000$

|            |    |    |    |    |    |    |    |      |      |      |      |            |    |    |    |
|------------|----|----|----|----|----|----|----|------|------|------|------|------------|----|----|----|
| 31         | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23   | 22   | 21   | 20   | 19         | 18 | 17 | 16 |
| AWLT[23:8] |    |    |    |    |    |    |    |      |      |      |      |            |    |    |    |

| AWLT[7:0]  |    |    |    |    |    |    |    | Res. | Res. | Res. | Res. | BKAWL[3:0] |    |    |    |
| rW         | rW | rW | rW | rW | rW | rW | rW |      |      |      |      | rW         | rW | rW | rW |

Bits 31:8 **AWLT[23:0]**: Analog watchdog low threshold

These bits are written by software to define the low threshold for the analog watchdog.

*Note: In case channel transceivers monitor (AWFSEL=1), only the higher 16 bits (AWLT[23:8]) define the 16-bit threshold as compared with the analog watchdog filter output (because data coming from the analog watchdog filter are up to a 16-bit resolution). Bits AWLT[7:0] are not taken into comparison in this case.*

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 **BKAWL[3:0]**: Break signal assignment to analog watchdog low threshold event

BKAWL[i] = 0: Break i signal is not assigned to an analog watchdog low threshold event

BKAWL[i] = 1: Break i signal is assigned to an analog watchdog low threshold event

### 24.8.11 DFSDM filter x analog watchdog status register (DFSDM\_FLTxAWSR)

Address offset:  $0x128 + 0x80 * x$ , ( $x = 0$  to  $3$ )

Reset value:  $0x0000\ 0000$

|            |      |      |      |      |      |      |      |            |      |      |      |      |      |      |      |
|------------|------|------|------|------|------|------|------|------------|------|------|------|------|------|------|------|
| 31         | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23         | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Res.       | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.       | Res. | Res. | Res. | Res. | Res. | Res. | Res. |
|            |      |      |      |      |      |      |      |            |      |      |      |      |      |      |      |
| 15         | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7          | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| AWHTF[7:0] |      |      |      |      |      |      |      | AWLTF[7:0] |      |      |      |      |      |      |      |
| r          | r    | r    | r    | r    | r    | r    | r    | r          | r    | r    | r    | r    | r    | r    | r    |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:8 **AWHTF[7:0]**: Analog watchdog high threshold flag

AWHTF[y]=1 indicates a high threshold error on channel y. It is set by hardware. It can be cleared by software using the corresponding CLRAWHTF[y] bit in the DFSDM\_FLTxAWCFR register.

Bits 7:0 **AWLTF[7:0]**: Analog watchdog low threshold flag

AWLTF[y]=1 indicates a low threshold error on channel y. It is set by hardware. It can be cleared by software using the corresponding CLRAWLTF[y] bit in the DFSDM\_FLTxAWCFR register.

*Note: All the bits of DFSDM\_FLTxAWSR are automatically reset when DFEN=0.*

### 24.8.12 DFSDM filter x analog watchdog clear flag register (DFSDM\_FLTxAWCFR)

Address offset:  $0x12C + 0x80 * x$ , ( $x = 0$  to  $3$ )

Reset value:  $0x0000\ 0000$

|              |       |       |       |       |       |       |       |               |       |       |       |       |       |       |       |

| 15           | 14    | 13    | 12    | 11    | 10    | 9     | 8     | 7             | 6     | 5     | 4     | 3     | 2     | 1     | 0     |
| CLRWHTF[7:0] |       |       |       |       |       |       |       | CLRAWLTF[7:0] |       |       |       |       |       |       |       |
| rc_w1        | rc_w1 | rc_w1 | rc_w1 | rc_w1 | rc_w1 | rc_w1 | rc_w1 | rc_w1         | rc_w1 | rc_w1 | rc_w1 | rc_w1 | rc_w1 | rc_w1 | rc_w1 |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:8 **CLRWHTF[7:0]**: Clear the analog watchdog high threshold flag

CLRWHTF[y]=0: Writing '0' has no effect

CLRWHTF[y]=1: Writing '1' to position y clears the corresponding AWHTF[y] bit in the DFSDM\_FLTxAWSR register

Bits 7:0 **CLRAWLTF[7:0]**: Clear the analog watchdog low threshold flag

CLRAWLTF[y]=0: Writing '0' has no effect

CLRAWLTF[y]=1: Writing '1' to position y clears the corresponding AWLTF[y] bit in the DFSDM\_FLTxAWSR register

### 24.8.13 DFSDM filter x extremes detector maximum register (DFSDM\_FLTxEVMAX)

Address offset:  $0x130 + 0x80 * x$ , ( $x = 0$  to  $3$ )

Reset value:  $0x8000\ 0000$

|             |      |      |      |      |      |      |      |      |      |      |      |      |              |      |      |
|-------------|------|------|------|------|------|------|------|------|------|------|------|------|--------------|------|------|
| 31          | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18           | 17   | 16   |
| EXMAX[23:8] |      |      |      |      |      |      |      |      |      |      |      |      |              |      |      |
| rs_r        | rc_r | rc_r | rc_r | rc_r | rc_r | rc_r | rc_r | rc_r | rc_r | rc_r | rc_r | rc_r | rc_r         | rc_r | rc_r |
| 15          | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2            | 1    | 0    |
| EXMAX[7:0]  |      |      |      |      |      |      |      | Res. | Res. | Res. | Res. | Res. | EXMAXCH[2:0] |      |      |
| rc_r        | rc_r | rc_r | rc_r | rc_r | rc_r | rc_r | rc_r |      |      |      |      |      | r            | r    | r    |

Bits 31:8 **EXMAX[23:0]**: Extremes detector maximum value

These bits are set by hardware and indicate the highest value converted by DFSDM\_FLTx.

EXMAX[23:0] bits are reset to value (0x800000) by reading of this register.

Bits 7:3 Reserved, must be kept at reset value.

Bits 2:0 **EXMAXCH[2:0]**: Extremes detector maximum data channel.

These bits contains information about the channel on which the data is stored into EXMAX[23:0].

Bits are cleared by reading of this register.

### 24.8.14 DFSDM filter x extremes detector minimum register (DFSDM\_FLTxEXMIN)

Address offset:  $0x134 + 0x80 * x$ , ( $x = 0$  to  $3$ )

Reset value:  $0x7FFF\ FF00$

|             |      |      |      |      |      |      |      |      |      |      |      |      |              |      |      |
|-------------|------|------|------|------|------|------|------|------|------|------|------|------|--------------|------|------|
| 31          | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18           | 17   | 16   |
| EXMIN[23:8] |      |      |      |      |      |      |      |      |      |      |      |      |              |      |      |
| rs_r        | rs_r | rs_r | rs_r | rs_r | rs_r | rs_r | rs_r | rs_r | rs_r | rs_r | rs_r | rs_r | rs_r         | rs_r | rs_r |
| 15          | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2            | 1    | 0    |
| EXMIN[7:0]  |      |      |      |      |      |      |      | Res. | Res. | Res. | Res. | Res. | EXMINCH[2:0] |      |      |
| rs_r        | rs_r | rs_r | rs_r | rs_r | rs_r | rs_r | rs_r |      |      |      |      |      | r            | r    | r    |

Bits 31:8 **EXMIN[23:0]**: Extremes detector minimum value

These bits are set by hardware and indicate the lowest value converted by DFSDM\_FLTx.

EXMIN[23:0] bits are reset to value ( $0x7FFFFFFF$ ) by reading of this register.

Bits 7:3 Reserved, must be kept at reset value.

Bits 2:0 **EXMINCH[2:0]**: Extremes detector minimum data channel

These bits contain information about the channel on which the data is stored into EXMIN[23:0]. Bits are cleared by reading of this register.

### 24.8.15 DFSDM filter x conversion timer register (DFSDM\_FLTxCNVTIMR)

Address offset:  $0x138 + 0x80 * x$ , ( $x = 0$  to  $3$ )

Reset value:  $0x0000\ 0000$

|               |    |    |    |    |    |    |    |    |    |    |    |      |      |      |      |
|---------------|----|----|----|----|----|----|----|----|----|----|----|------|------|------|------|
| 31            | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19   | 18   | 17   | 16   |
| CNVCNT[27:12] |    |    |    |    |    |    |    |    |    |    |    |      |      |      |      |
| r             | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r    | r    | r    | r    |
| 15            | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3    | 2    | 1    | 0    |
| CNVCNT[11:0]  |    |    |    |    |    |    |    |    |    |    |    | Res. | Res. | Res. | Res. |
| r             | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  |      |      |      |      |

Bits 31:4 **CNVCNT[27:0]**: 28-bit timer counting conversion time  $t = \text{CNVCNT}[27:0] / f_{\text{DFSDMCLK}}$

The timer has an input clock from DFSDM clock (system clock  $f_{\text{DFSDMCLK}}$ ). Conversion time measurement is started on each conversion start and stopped when conversion finishes (interval between first and last serial sample). Only in case of filter bypass ( $\text{FOSR}[9:0] = 0$ ) is the conversion time measurement stopped and  $\text{CNVCNT}[27:0] = 0$ . The counted time is:

if  $\text{FAST}=0$  (or first conversion in continuous mode if  $\text{FAST}=1$ ):

$$t = [\text{F}_{\text{OSR}} * (\text{I}_{\text{OSR}} - 1 + \text{F}_{\text{ORD}}) + \text{F}_{\text{ORD}}] / f_{\text{CKIN}} \dots \text{for Sinc}^x \text{ filters}$$

$$t = [\text{F}_{\text{OSR}} * (\text{I}_{\text{OSR}} - 1 + 4) + 2] / f_{\text{CKIN}} \dots \text{for FastSinc filter}$$

if  $\text{FAST}=1$  in continuous mode (except first conversion):

$$t = [\text{F}_{\text{OSR}} * \text{I}_{\text{OSR}}] / f_{\text{CKIN}}$$

in case if  $\text{F}_{\text{OSR}} = \text{FOSR}[9:0] + 1 = 1$  (filter bypassed, active only integrator):

$$\text{CNVCNT} = 0 \text{ (counting is stopped, conversion time: } t = \text{I}_{\text{OSR}} / f_{\text{CKIN}})$$

where:  $f_{\text{CKIN}}$  is the channel input clock frequency (on given channel CKINy pin) or input data rate in case of parallel data input (from internal ADC<sup>(1)</sup> or from CPU/DMA write)

*Note: When conversion is interrupted (e.g. by disable/enable selected channel) the timer counts also this interruption time.*

Bits 3:0 Reserved, must be kept at reset value.

1. Availability of the input from internal ADC is device dependent, see [Table 155: DFSDM1 implementation](#).

## 24.8.16 DFSDM register map

The following table summarizes the DFSDM registers.

**Table 163. DFSDM register map and reset values**

| Offset      | Register name   | 31           | 30       | 29   | 28   | 27   | 26   | 25   | 24   | 23            | 22   | 21          | 20   | 19   | 18   | 17         | 16           | 15           | 14          | 13          | 12   | 11   | 10        | 9    | 8          | 7    | 6      | 5     | 4    | 3              | 2    | 1         | 0 |

1. Availability of the input from internal ADC is device dependent, see [Table 155: DFSDM1 implementation](#).

Refer to [Section 2.2 on page 75](#) for the register boundary addresses.

## 25 Liquid crystal display controller (LCD)

This section applies to STM32L4x6 devices only.

### 25.1 LCD introduction

The LCD controller is a digital controller/driver for monochrome passive liquid crystal display (LCD) with up to eight common terminals, and up to 44 segment terminals to drive 176 (44x4) or 320 (40x8) LCD picture elements (pixels). The exact number of terminals depends on the device pinout as described in the datasheet.

The LCD is made up of several segments (pixels or complete symbols) that can be turned visible or invisible. Each segment consists of a layer of liquid crystal molecules aligned between two electrodes. When a voltage greater than a threshold voltage is applied across the liquid crystal, the segment becomes visible. The segment voltage must be alternated to avoid an electrophoresis effect in the liquid crystal (which degrades the display). The waveform across a segment must then be generated, so to avoid having a direct current (DC).

#### Glossary

**Bias:** number of voltage levels used when driving an LCD

It is defined as  $1 / (\text{number of voltage levels used to drive an LCD display} - 1)$ .

**Boost circuit:** contrast controller circuit

**Common:** electrical connection terminal connected to several segments (44 segments)

**Duty ratio:** number defined as  $1 / (\text{number of common terminals on a given LCD display})$

**Frame:** one period of the waveform written to a segment

**Frame rate:** number of frames per second (number of times the LCD segments are energized per second)

**LCD** (liquid crystal display): passive display panel with terminals leading directly to a segment

**Segment:** smallest viewing element (a single bar or dot that is used to help create a character on an LCD display)

### 25.2 LCD main features

- Highly flexible frame rate control
- Static, 1/2, 1/3, 1/4, and 1/8 duty supported
- Static, 1/2, 1/3, and 1/4 bias supported
- Double-buffered memory allowing data in LCD\_RAM registers to be updated at any time by the application firmware without affecting the integrity of the data displayed
  - LCD data RAM of up to 16 x 32-bit registers which contain pixel information (active/inactive)
- Software selectable LCD output voltage (contrast) from  $V_{\text{LCDmin}}$  to  $V_{\text{LCDmax}}$

- No need for external analog components:
  - stepup converter embedded to generate an internal  $V_{LCD}$  voltage higher than  $V_{DD}$
  - software selection between external and internal  $V_{LCD}$  voltage source. In case of an external source, the internal boost circuit is disabled to reduce power consumption.
  - resistive network embedded to generate intermediate  $V_{LCD}$  voltages
  - structure of the resistive network configurable by software to adapt the power consumption to match the capacitive charge required by the LCD panel
  - Integrated voltage output buffers for higher LCD driving capability.
- Contrast that can be adjusted using two different methods:
  - When using the internal step-up converter, the software can adjust  $V_{LCD}$  between  $V_{LCDmin}$  and  $V_{LCDmax}$ .
  - Programmable dead time (up to eight phase periods) between frames
- Full support of low-power modes: The LCD controller can be displayed in Sleep, Low-power run, Low-power sleep, and Stop modes, or can be fully disabled to reduce power consumption.
- Built-in phase inversion for reduced power consumption and EMI (electromagnetic interference)
- Start-of-frame interrupt to synchronize the software when updating the LCD data RAM
- Blink capability:
  - Up to 1, 2, 3, 4, 8, or all pixels which can be programmed to blink at a configurable frequency
  - Software adjustable blink frequency to achieve around 0.5 Hz, 1 Hz, 2 Hz, or 4 Hz
- Used LCD segment and common pins must be configured as GPIO alternate functions, and unused segment and common pins can be used for GPIO or for another peripheral alternate function.

**Note:** *When the LCD relies on the internal stepup converter, the VLCD pin must be connected to  $V_{SS}$  with a capacitor. Its typical value is 1  $\mu F$  (see  $C_{EXT}$  value in the datasheet for details).*

## 25.3 LCD functional description

### 25.3.1 General description

The LCD controller has five main blocks (see [Figure 171](#)):

Figure 171. LCD controller block diagram

**Note:** *LCDCLK is the same as RTCCLK. Refer to the RTC/LCD clock description in the RCC section of the reference manual.*

The frequency generator allows the user to achieve various LCD frame rates starting from an LCD input clock frequency (LCDCLK) which can vary from 32 kHz up to 1 MHz.

Three different clock sources can be used to provide the LCD clock (LCDCLK/RTCCLK):

- 32 kHz low-speed external RC (LSE)
- 32 kHz low-speed internal RC (LSI)
- high-speed external (HSE) divided by 32

### 25.3.2 Frequency generator

This clock source must be stable in order to obtain accurate LCD timing, and hence to minimize DC voltage offset across LCD segments. The input clock LCDCLK can be divided by any value from 1 to  $2^{15} \times 31$  (see [Section 25.6.2](#)). The frequency generator consists of a prescaler (16-bit ripple counter), and a 16 to 31 clock divider.

PS[3:0] in LCD\_FCR selects LCDCLK divided by  $2^{PS[3:0]}$ . If a finer resolution rate is required, DIV[3:0] in LCD\_FCR can be used to divide the clock further by 16 to 31.

In this way, the user can roughly scale the frequency, and then fine-tune it by linearly scaling the clock with the counter. The output of the frequency generator block is  $f_{ck\_div}$ , which constitutes the time base for the entire LCD controller. The  $ck\_div$  frequency is equivalent to the LCD phase frequency, rather than the frame frequency (they are equal only in case of static duty). The frame frequency ( $f_{frame}$ ) is obtained from  $f_{ck\_div}$  by dividing it by the number of active common terminals (or by multiplying it for the duty). Thus the relation between the input clock frequency ( $f_{LCDCLK}$ ) of the frequency generator and its output clock frequency  $f_{ck\_div}$  is:

$$f_{ckdiv} = \frac{f_{LCDCLK}}{2^{PS} \times (16 + DIV)}$$

$$f_{frame} = f_{ckdiv} \times \text{duty}$$

This makes the frequency generator very flexible. An example of frame rate calculation is shown in the table below.

**Table 164. Example of frame rate calculation**

| LCDCLK     | PS[3:0] | DIV[3:0] | Ratio | Duty   | $f_{frame}$ |
|------------|---------|----------|-------|--------|-------------|
| 32.768 kHz | 3       | 1        | 136   | 1/8    | 30.12 Hz    |
| 32.768 kHz | 4       | 1        | 272   | 1/4    | 30.12 Hz    |
| 32.768 kHz | 4       | 6        | 352   | 1/3    | 31.03 Hz    |
| 32.768 kHz | 5       | 1        | 544   | 1/2    | 30.12 Hz    |
| 32.768 kHz | 6       | 1        | 1088  | static | 30.12 Hz    |
| 32.768 kHz | 1       | 4        | 40    | 1/8    | 102.40 Hz   |
| 32.768 kHz | 2       | 4        | 80    | 1/4    | 102.40 Hz   |
| 32.768 kHz | 2       | 11       | 108   | 1/3    | 101.14 Hz   |
| 32.768 kHz | 3       | 4        | 160   | 1/2    | 102.40 Hz   |
| 32.768 kHz | 4       | 4        | 320   | static | 102.40 Hz   |
| 1.00 MHz   | 6       | 3        | 1216  | 1/8    | 102.80 Hz   |
| 1.00 MHz   | 7       | 3        | 2432  | 1/4    | 102.80 Hz   |
| 1.00 MHz   | 7       | 10       | 3328  | 1/3    | 100.16 Hz   |
| 1.00 MHz   | 8       | 3        | 4864  | 1/2    | 102.80 Hz   |
| 1.00 MHz   | 9       | 3        | 9728  | static | 102.80 Hz   |

The frame frequency must be selected to be within a range of around ~30 Hz to ~100 Hz. It is a compromise between power consumption and the acceptable refresh rate. In addition, a dedicated blink prescaler selects the blink frequency. This frequency is defined as:

$$f_{\text{BLINK}} = f_{\text{ck\_div}} / 2^{(\text{BLINKF} + 3)},$$

with  $\text{BLINKF}[2:0] = 0, 1, 2, \dots, 7$

The blink frequency achieved is in the range of 0.5 Hz, 1 Hz, 2 Hz, or 4 Hz.

### 25.3.3 Common driver

Common signals are generated by the common driver block (see [Figure 171](#)).

#### COM signal bias

Each COM signal has identical waveforms, but different phases. It has its max amplitude  $V_{\text{LCD}}$  or  $V_{\text{SS}}$  only in the corresponding phase of a frame cycle, while during the other phases, the signal amplitude is:

- $1/4 V_{\text{LCD}}$  or  $3/4 V_{\text{LCD}}$  in case of  $1/4$  bias
- $1/3 V_{\text{LCD}}$  or  $2/3 V_{\text{LCD}}$  in case of  $1/3$  bias
- $1/2 V_{\text{LCD}}$  in case of  $1/2$  bias

The selection between  $1/2$ ,  $1/3$ , and  $1/4$  bias mode can be done through  $\text{BIAS}[1:0]$  in  $\text{LCD\_CR}$ .

A pixel is activated when both of its corresponding common and segment lines are active during the same phase: when the voltage difference between common and segment is maximum during this phase. Common signals are phase inverted in order to reduce EMI.

As shown in the figure below, with phase inversion, there is a mean voltage of  $1/2 V_{\text{LCD}}$  at the end of every odd cycle.

Figure 172.  $1/3$  bias,  $1/4$  duty

In case of  $1/2$  bias ( $\text{BIAS} = 01$ ), the  $V_{\text{LCD}}$  pin generates an intermediate voltage equal to  $1/2 V_{\text{LCD}}$  on node b for odd and even frames (see [Figure 175](#)).

### COM signal duty

Depending on DUTY[2:0] in LCD\_CR, the COM signals are generated with static duty (see [Figure 174](#)), 1/2 duty (see [Figure 175](#)), 1/3 duty (see [Figure 176](#)), 1/4 duty (see [Figure 177](#)), or 1/8 duty (see [Figure 178](#)).

COM[ $n$ ]  $n[0$  to 7] is active during phase  $n$  in the odd frame, so the COM pin is driven to  $V_{LCD}$ .

During phase  $n$  of the even frame, the COM pin is driven to  $V_{SS}$ .

In the case of 1/3 or 1/4 bias, COM[ $n$ ] is inactive during phases other than  $n$ , so the COM pin is driven to 1/3 (1/4)  $V_{LCD}$  during odd frames, and to 2/3 (3/4)  $V_{LCD}$  during even frames.

In the case of 1/2 bias, if COM[ $n$ ] is inactive during phases other than  $n$ , the COM pin is always driven (odd and even frame) to 1/2  $V_{LCD}$ .

When static duty is selected, the segment lines are not multiplexed, which means that each segment output corresponds to one pixel. In this way, only up to 44 pixels can be driven. COM[0] is always active while COM[7:1] are not used and are driven to  $V_{SS}$ .

When LCDEN in LCD\_CR is reset, all common lines are pulled down to  $V_{SS}$ , and the ENS flag in LCD\_SR becomes 0. Static duty means that COM[0] is always active, and only two voltage levels are used for segment and common lines:  $V_{LCD}$  and  $V_{SS}$ . A pixel is active if the corresponding SEG line has a voltage opposite to that of the COM, and inactive when the voltages are equal. In this way the LCD has maximum contrast (see [Figure 173](#), [Figure 174](#)).

In the figure below, pixel 0 is active while pixel 1 is inactive.

**Figure 173. Static duty case 1**

In each frame, there is only one phase, this is why  $f_{frame}$  is equal to  $f_{LCD}$ . If 1/4 duty is selected there are four phases in a frame in which COM[0] is active during phase 0, COM[1] is active during phase 1, COM[2] is active during phase 2, and COM[3] is active during phase 3.

Figure 174. Static duty case 2

In this mode, the segment terminals are multiplexed, and each of them control four pixels. A pixel is activated only when both of its corresponding SEG and COM lines are active in the same phase. In case of 1/4 duty, to deactivate pixel 0 connected to COM[0], SEG[0] needs to be inactive during the phase 0 when COM[0] is active. To activate pixel 0 connected to COM[1], SEG[0] needs to be active during phase 1 when COM[1] is active (see [Figure 177](#)). To activate pixels from 0 to 43 connected to COM[0], SEG[0:43] needs to be active during phase 0 when COM[0] is active. These considerations can be extended to the other pixels.

### Eight-to-one mux

When COM[0] is active the common driver block, it also drives the eight-to-one mux shown in [Figure 171](#) in order to select the content of first two RAM register locations. When COM[7] is active, the output of the eight-to-one mux is the content of the last two RAM locations.

Figure 175. 1/2 duty, 1/2 bias

### 25.3.4 Segment driver

The segment driver block controls the SEG lines according to the pixel data coming from the eight-to-one mux driven in each phase by the common driver block.

#### In the case of 1/4 or 1/8 duty

When COM[0] is active, the pixel information (active/inactive) related to the pixel connected to COM[0] (content of the first two LCD\_RAM locations) goes through the eight-to-one mux.

The SEG[n] pin  $n$  [0 to 43] is driven to  $V_{SS}$  (indicating pixel  $n$  is active when COM[0] is active) in phase 0 of the odd frame.

The SEG[n] pin is driven to  $V_{LCD}$  in phase 0 of the even frame. If pixel  $n$  is inactive then the SEG[n] pin is driven to  $2/3$  ( $2/4$ )  $V_{LCD}$  in the odd frame or  $1/3$  ( $2/4$ )  $V_{LCD}$  in the even frame (current inversion in  $V_{LCD}$  pad) (see [Figure 172](#)).

In case of 1/2 bias, if the pixel is inactive the SEG[n] pin is driven to  $V_{LCD}$  in the odd and to  $V_{SS}$  in the even frame.

When the LCD controller is disabled (LCDEN cleared in LCD\_CR), then the SEG lines are pulled down to  $V_{SS}$ .

Figure 176. 1/3 duty, 1/3 bias

Figure 177. 1/4 duty, 1/3 bias

**Figure 178. 1/8 duty, 1/4 bias**

## Blink

The segment driver also implements a programmable blink feature to allow some pixels to continuously switch on at a specific frequency. The blink mode can be configured by BLINK[1:0] in LCD\_FCR, making possible to blink up to 1, 2, 4, 8, or all pixels (see [Section 25.6.2](#)). The blink frequency can be selected from eight different values using BLINKF[2:0] in LCD\_FCR.

The table below gives examples of different blink frequencies (as a function of ck\_div frequency).

**Table 165. Blink frequency**

| BLINKF[2:0] |   |   | ck_div frequency (with LCDCLK frequency of 32.768 kHz) |         |         |         |
|-------------|---|---|--------------------------------------------------------|---------|---------|---------|
|             |   |   | 32 Hz                                                  | 64 Hz   | 128 Hz  | 256 Hz  |
| 0           | 0 | 0 | 4.0 Hz                                                 | N/A     | N/A     | N/A     |
| 0           | 0 | 1 | 2.0 Hz                                                 | 4.0 Hz  | N/A     | N/A     |
| 0           | 1 | 0 | 1.0 Hz                                                 | 2.0 Hz  | 4.0 Hz  | N/A     |
| 0           | 1 | 1 | 0.5 Hz                                                 | 1.0 Hz  | 2.0 Hz  | 4.0 Hz  |
| 1           | 0 | 0 | 0.25 Hz                                                | 0.5 Hz  | 1.0 Hz  | 2.0 Hz  |
| 1           | 0 | 1 | N/A                                                    | 0.25 Hz | 0.5 Hz  | 1.0 Hz  |
| 1           | 1 | 0 | N/A                                                    | N/A     | 0.25 Hz | 0.5 Hz  |
| 1           | 1 | 1 | N/A                                                    | N/A     | N/A     | 0.25 Hz |

## 25.3.5 Voltage generator and contrast control

### LCD supply source

The LCD power supply source comes from either the internal stepup converter, or from an external voltage applied on the VLCD pin. The internal or external voltage source can be selected using VSEL in LCD\_CR. In case of external source selected, the internal boost circuit (stepup converter) is disabled to reduce power consumption.

When the stepup converter is selected as  $V_{LCD}$  source, the  $V_{LCD}$  value can be chosen among a wide set of values from  $V_{LCDmin}$  to  $V_{LCDmax}$  by means of CC[2:0] (contrast control) in LCD\_FCR (see [Section 25.6.2](#)). New values of  $V_{LCD}$  takes effect every beginning of a new frame.

When external power source is selected as  $V_{LCD}$  source, the  $V_{LCD}$  voltage must be chosen in the range of  $V_{LCDmin}$  to  $V_{LCDmax}$  (see datasheets). The contrast can then be controlled by programming a dead time between frames (see [Deadtime](#)).

A specific software sequence must be performed to configure the LCD depending on the LCD power supply source to be used. The LCD controller is considered as disabled prior to the configuration sequence.

In case the internal stepup converter is used (capacitor  $C_{EXT}$  on VLCD pin is required):

- Configure the VLCD pin as alternate function LCD in the GPIO\_AFR register.
- Wait for the external capacitor  $C_{EXT}$  to be charged ( $C_{EXT}$  connected to the VLCD pin, approximately 2 ms for  $C_{EXT} = 1 \mu F$ )

- Set voltage source to internal source by resetting VSEL in LCD\_CR.
- Enable the LCD controller by setting LCDEN in LCD\_CR.

In case of LCD external power source is used:

- Set voltage source to external source by setting VSEL in LCD\_CR.
- Configure the VLCD pin as alternate function LCD in GPIO\_AFR.
- Enable the LCD controller by setting LCDEN in LCD\_CR.

### LCD intermediate voltages

The LCD intermediate voltage levels are generated through an internal resistor divider network as shown in [Figure 179](#).

The LCD voltage generator issues intermediate voltage levels between  $V_{SS}$  and  $V_{LCD}$ :

- $1/3 V_{LCD}$  and  $2/3 V_{LCD}$  in case of 1/3 bias
- $1/4 V_{LCD}$ ,  $2/4 V_{LCD}$  and  $3/4 V_{LCD}$  in case of 1/4 bias
- only  $1/2 V_{LCD}$  in case of 1/2 bias.

### LCD drive selection

Two resistive networks, one with low-value resistors ( $R_L$ ), and one with high-value resistors ( $R_H$ ) are respectively used to increase the current during transitions, and to reduce power consumption in static state.

The EN switch follows the rules described below (see [Figure 179](#)):

- If LCDEN is set in LCD\_CR, the EN switch is closed.
- When clearing LCDEN in LCD\_CR, the EN switch is open at the end of the even frame in order to avoid a medium voltage level different from 0 considering the entire frame odd plus even.

PON[2:0] (pulse on duration) in LCD\_FCR configures the time during which  $R_L$  is enabled through the HD (high drive) switch when the levels of the common and segment lines change (see [Figure 179](#)). A short drive time leads to lower power consumption, but displays with high internal resistance may need a longer drive time to achieve satisfactory contrast.

Figure 179. LCD voltage control

1.  $R_{LN}$  and  $R_{HN}$  are the low value resistance network and the high value resistance network, respectively.

The  $R_{LN}$  divider can be always switched on using HD in LCD\_FCR (see [Section 25.6.2](#)).

The HD switch follows the rules described below:

- If HD and PON[2:0] are reset in LCD\_FCR, the HD switch is open.
- If HD is reset in LCD\_FCR, and PON[2:0] in LCD\_FCR are different from 00, the HD switch is closed during the number of pulses defined in PON[2:0].
- If HD = 1 in LCD\_FCR, then HD switch is always closed.

After LCDEN is activated, RDY is set in LCD\_SR to indicate that voltage levels are stable and the LCD controller can start to work.

### Buffered mode

When voltage output buffers are enabled by setting BUFEN in LCD\_CR, the LCD driving capability is improved as buffers prevent the LCD capacitive loads from loading the resistor bridge unacceptably and interfering with its voltage generation. As a result, intermediate voltage levels are more stable, which improves RMS voltage applied to the LCD pixels.

In buffer mode, intermediate voltages are generated by the high value resistor bridge  $R_{HN}$  to reduce power consumption. The low value resistor bridge  $R_{LN}$  is automatically disabled whatever HD or PON[2:0] configuration.

Buffers can be used independently of the  $V_{LCD}$  supply source (internal or external), but they can only be enabled or disabled when the LCD controller is not activated.

### Deadtime

In addition to using CC[2:0], the contrast can be controlled by programming a dead time between each frame. During the dead time, the COM and SEG values are put to  $V_{SS}$ . DEAD[2:0] in LCD\_FCR can be used to program a time of up to eight phase periods. This dead time reduces the contrast without modifying the frame rate.

Figure 180. Deadtime

### 25.3.6 Double-buffer memory

Using its double-buffer memory, the LCD controller ensures the coherency of the displayed information without having to use interrupts to control the LCD\_RAM modification.

The application software can access the first buffer level (LCD\_RAM) through the APB interface. Once it has modified the LCD\_RAM, it sets UDR in LCD\_SR. This UDR flag (update display request) requests the updated information to be moved into the second buffer level (LCD\_DISPLAY).

This operation is done synchronously with the frame (at the beginning of the next frame). Until the update is completed, the LCD\_RAM is write protected, and the UDR flag stays high. Once the update is completed, another flag (UDD, update display done) is set and generates an interrupt if UDDIE is set in LCD\_FCR.

The time it takes to update LCD\_DISPLAY is, in the worst case, one odd and one even frame.

The update does not occur (UDR = 1 and UDD = 0) until the display is enabled (LCDEN = 1)

### 25.3.7 COM and SEG multiplexing

#### Output pins versus duty modes

The output pins consists of:

- SEG[43:0]
- COM[3:0]

Depending on the duty configuration, the COM and SEG output pins can have different functions:

- In static, 1/2, 1/3, and 1/4 duty modes, there are up to 44 SEG pins and respectively 1, 2, 3, and 4 COM pins
- In 1/8 duty mode (DUTY[2:0] = 100), COM[7:4] outputs are available on SEG[43:40] pins, reducing to the number of available segments to 40.

### Remapping capability for small packages

Additionally, it is possible to remap four segments by setting MUX\_SEG in LCD\_CR. This is particularly useful when using smaller device types with fewer external pins.

When MUX\_SEG is set, output pins SEG[43:40] have the same function as SEG[31:28].

This feature is available only if the mode 1/8 duty is not selected.

Check the availability of this feature by referring to the pinout section of the datasheet.

For the considered package, check the availability of the SEG/COM multiplexing pin as follow (n = number of segment for the considered package):

- LCD\_SEG[n-1]/LCD\_COM7/LCD\_SEG[31]
- LCD\_SEG[n-2]/LCD\_COM6/LCD\_SEG[30]
- LCD\_SEG[n-3]/LCD\_COM5/LCD\_SEG[29]
- LCD\_SEG[n-4]/LCD\_COM4/LCD\_SEG[28]

### Summary of COM and SEG functions versus duty and remap

All the possible ways of multiplexing the COM and SEG functions are described in the table below.

**Table 166. Remapping capability**

| Configuration bits |         | SEG x COM         |                                | Output pin                     | Function  |
|--------------------|---------|-------------------|--------------------------------|--------------------------------|-----------|
| DUTY               | MUX_SEG | WLCSP72<br>LQFP64 | LQFP144<br>UFBGA132<br>LQFP100 |                                |           |
| 1/8                | 0/1     | -                 | 40x8                           | SEG[43:40]/SEG[31:28]/COM[7:4] | COM[7:4]  |
|                    |         |                   |                                | COM[3:0]                       | COM[3:0]  |
|                    |         |                   |                                | SEG[39:0]                      | SEG[39:0] |
|                    | 0/1     | 28x8              | -                              | SEG[43:40]/SEG[31:28]/COM[7:4] | COM[7:4]  |
|                    |         |                   |                                | COM[3:0]                       | COM[3:0]  |
|                    |         |                   |                                | SEG[27:0]                      | SEG[27:0] |

Table 166. Remapping capability (continued)

| Configuration bits |           | SEG x COM         |                                | Output pin                     | Function                       |            |
|--------------------|-----------|-------------------|--------------------------------|--------------------------------|--------------------------------|------------|
| DUTY               | MUX_SEG   | WLCSP72<br>LQFP64 | LQFP144<br>UFBGA132<br>LQFP100 |                                |                                |            |
| 1/4                | 0         | -                 | 44x4                           | COM[3:0]                       | COM[3:0]                       |            |

|                                |         |                   |                                | SEG[43:40]/SEG[31:28]/COM[7:4] | SEG[31:28] |
|                                |         |                   |                                | SEG[39:32]                     | SEG[39:32] |
|                                |         | SEG[31:28]        |                                | not used                       |            |
|                                |         | SEG[27:0]         |                                | SEG[27:0]                      |            |
|                                | 0       | 28x1              | -                              | COM[3:1]                       | not used   |
|                                |         |                   |                                | COM0                           | COM0       |
|                                |         |                   |                                | SEG[43:40]/SEG[31:28]/COM[7:4] | not used   |
|                                |         |                   |                                | SEG[27:0]                      | SEG[27:0]  |
|                                | 1       | 32x1              |                                | COM[3:1]                       | not used   |
|                                |         |                   |                                | COM0                           | COM0       |
| SEG[43:40]/SEG[31:28]/COM[7:4] |         |                   |                                | SEG[31:28]                     |            |
| SEG[27:0]                      |         |                   |                                | SEG[27:0]                      |            |

The figure below gives examples showing the signal connections to the external pins.

Figure 181. SEG/COM mux feature example

## 25.3.8 Flowchart

Figure 182. Flowchart example

## 25.4 LCD low-power modes

The LCD controller can be displayed in Stop mode, or can be fully disabled to reduce power consumption.

**Table 167. LCD behavior in low-power modes**

| Mode            | Description                                                                               |
|-----------------|-------------------------------------------------------------------------------------------|
| Sleep           | No effect. LCD interrupt causes the device to exit Sleep mode.                            |
| Low-power Run   | No effect                                                                                 |
| Low-power Sleep | No effect. LCD interrupt causes the device to exit Low-power Sleep mode.                  |
| Stop 0          | No effect. LCD interrupt causes the device to exit Stop mode.                             |
| Stop 1          |                                                                                           |
| Stop 2          |                                                                                           |
| Standby         | The LCD is powered down and must be reinitialized after exiting Standby or Shutdown mode. |
| Shutdown        |                                                                                           |

## 25.5 LCD interrupts

The table below gives the list of LCD interrupt requests.

**Table 168. LCD interrupt requests**

| Interrupt event           | Event flag | Event flag<br>Interrupt clearing method | Interrupt enable<br>control bit |
|---------------------------|------------|-----------------------------------------|---------------------------------|
| Start of frame (SOF)      | SOF        | Write SOFC = 1                          | SOFIE                           |
| Update display done (UDD) | UDD        | Write UDDC = 1                          | UDDIE                           |

### Start of frame (SOF)

The LCD start of frame interrupt is executed if SOFIE (start of frame interrupt enable) is set in LCD\_FCR. SOF is cleared by writing SOFC to 1 in LCD\_CLR when executing the corresponding interrupt handling vector.

### Update display done (UDD)

The LCD update display interrupt is executed if UDDIE (update display done interrupt enable) is set in LCD\_FCR. UDD is cleared by writing th UDDC to 1 in LCD\_CLR when executing the corresponding interrupt handling vector.

Depending on the product implementation, all these interrupts events can either share the same interrupt vector (LCD global interrupt), or be grouped into two interrupt vectors (LCD SOF interrupt and LCD UDD interrupt). Refer to the [Table 58: STM32L47x/L48x/L49x/L4Ax vector table](#) for details.

To enable the LCD interrupts, the following sequence is required:

1. Configure and enable the LCD IRQ channel in the NVIC.
2. Configure the LCD to generate interrupts.

## 25.6 LCD registers

These registers are accessed by words (32-bit).

### 25.6.1 LCD control register (LCD\_CR)

Address offset: 0x00

Reset value: 0x0000 0000

VSEL, MUX\_SEG, BIAS, DUTY, and BUFEN bitfields are write-protected when the LCD is enabled (ENS =1 in LCD\_SR).

|      |      |      |      |      |      |      |       |         |           |      |           |      |      |      |       |
|------|------|------|------|------|------|------|-------|---------|-----------|------|-----------|------|------|------|-------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24    | 23      | 22        | 21   | 20        | 19   | 18   | 17   | 16    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.  | Res.    | Res.      | Res. | Res.      | Res. | Res. | Res. | Res.  |
|      |      |      |      |      |      |      |       |         |           |      |           |      |      |      |       |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8     | 7       | 6         | 5    | 4         | 3    | 2    | 1    | 0     |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | BUFEN | MUX_SEG | BIAS[1:0] |      | DUTY[2:0] |      |      | VSEL | LCDEN |
|      |      |      |      |      |      |      | rw    | rw      | rw        | rw   | rw        | rw   | rw   | rw   | rw    |

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **BUFEN**: Voltage output buffer enable

This bit is used to enable/disable the voltage output buffer for higher driving capability.

0: Output buffer disabled

1: Output buffer enabled

Bit 7 **MUX\_SEG**: Mux segment enable

This bit is used to enable SEG pin remapping. Four SEG pins can be multiplexed with SEG[31:28]. See [Section 25.3.7](#).

0: SEG pin multiplexing disabled

1: SEG[31:28] multiplexed with SEG[43:40]

Bits 6:5 **BIAS[1:0]**: Bias selector

These bits determine the bias used. Value 11 is forbidden.

00: Bias 1/4

01: Bias 1/2

10: Bias 1/3

11: Reserved

Bits 4:2 **DUTY[2:0]**: Duty selection

These bits determine the duty cycle. Values 101, 110 and 111 are forbidden.

000: Static duty

001: 1/2 duty

010: 1/3 duty

011: 1/4 duty

100: 1/8 duty

Others: Reserved

Bit 1 **VSEL**: Voltage source selection

This bit determines the voltage source for the LCD.

0: Internal source (voltage stepup converter)

1: External source (VLCD pin)

Bit 0 **LCDEN**: LCD controller enable

This bit is set by software to enable the LCD controller/driver. It is cleared by software to turn off the LCD at the beginning of the next frame. When the LCD is disabled, all COM and SEG pins are driven to  $V_{SS}$ .

0: LCD controller disabled

1: LCD controller enabled

## 25.6.2 LCD frame control register (LCD\_FCR)

Address offset: 0x04

Reset value: 0x0000 0000

This register can be updated any time, but the new values are applied only at the beginning of the next frame (except for UDDIE, SOFIE that affect the device behavior immediately). The new value of CC[2:0] is also applied immediately, but its effect on the device is delayed at the beginning of the next frame by the voltage generator.

Reading this register gives the last value written in the register, and not the configuration used to display the current frame.

When BUFEN is set in LCD\_CR, the low resistor divider network is automatically disabled whatever HD or PON[2:0] configuration.

|             |      |      |         |      |      |           |    |    |          |          |    |       |      |            |    |
|-------------|------|------|---------|------|------|-----------|----|----|----------|----------|----|-------|------|------------|----|
| 31          | 30   | 29   | 28      | 27   | 26   | 25        | 24 | 23 | 22       | 21       | 20 | 19    | 18   | 17         | 16 |

|             |      |      |         |      |      | rw        | rw | rw | rw       | rw       | rw | rw    | rw   | rw         | rw |
| 15          | 14   | 13   | 12      | 11   | 10   | 9         | 8  | 7  | 6        | 5        | 4  | 3     | 2    | 1          | 0  |
| BLINKF[2:0] |      |      | CC[2:0] |      |      | DEAD[2:0] |    |    | PON[2:0] |          |    | UDDIE | Res. | SOFIE      | HD |
| rw          | rw   | rw   | rw      | rw   | rw   | rw        | rw | rw | rw       | rw       | rw | rw    |      | rw         | rw |

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:22 **PS[3:0]**: PS 16-bit prescaler

These bits are written by software to define the division factor of the PS 16-bit prescaler.  
 $ck\_ps = LCDCLK / (2^{PS[3:0]})$ . See [Section 25.3.2](#).

0000:  $ck\_ps = LCDCLK$

0001:  $ck\_ps = LCDCLK/2$

0002:  $ck\_ps = LCDCLK/4$

...

1111:  $ck\_ps = LCDCLK/32768$

Bits 21:18 **DIV[3:0]**: DIV clock divider

These bits are written by software to define the division factor of the DIV divider (see [Section 25.3.2](#).)

0000:  $ck\_div = ck\_ps/16$

0001:  $ck\_div = ck\_ps/17$

0002:  $ck\_div = ck\_ps/18$

...

1111:  $ck\_div = ck\_ps/31$

Bits 17:16 **BLINK[1:0]**: Blink mode selection

- 00: Blink disabled
- 01: Blink enabled on SEG[0], COM[0] (1 pixel)
- 10: Blink enabled on SEG[0], all COMs (up to 8 pixels depending on the programmed duty)
- 11: Blink enabled on all SEGs and all COMs (all pixels)

Bits 15:13 **BLINKF[2:0]**: Blink frequency selection

- 000:  $f_{LCD}/8$
- 001:  $f_{LCD}/16$
- 010:  $f_{LCD}/32$
- 011:  $f_{LCD}/64$
- 100:  $f_{LCD}/128$
- 101:  $f_{LCD}/256$
- 110:  $f_{LCD}/512$
- 111:  $f_{LCD}/1024$

Bits 12:10 **CC[2:0]**: Contrast control

These bits specify one of the  $V_{LCD}$  maximum voltages (independent of  $V_{DD}$ ). It ranges from 2.60 V to 3.51V.

- 000:  $V_{LCD0}$
- 001:  $V_{LCD1}$
- 010:  $V_{LCD2}$
- 011:  $V_{LCD3}$
- 100:  $V_{LCD4}$
- 101:  $V_{LCD5}$
- 110:  $V_{LCD6}$
- 111:  $V_{LCD7}$

*Note: Refer to the datasheet for the  $V_{LCDx}$  values.*

Bits 9:7 **DEAD[2:0]**: Dead time duration

These bits are written by software to configure the length of the dead time between frames. During the dead time the COM and SEG voltage levels are held at 0 V to reduce the contrast without modifying the frame rate.

- 000: No dead time
- 001: 1 phase period dead time
- 010: 2 phase period dead time
- .....
- 111: 7 phase period dead time

Bits 6:4 **PON[2:0]**: Pulse ON duration

These bits are written by software to define the pulse duration in terms of ck\_ps pulses. A short pulse leads to lower power consumption, but displays with high internal resistance may need a longer pulse to achieve satisfactory contrast.

Note that the pulse is never longer than one half prescaled LCD clock period.

000: 0

001: 1/ck\_ps

010: 2/ck\_ps

011: 3/ck\_ps

100: 4/ck\_ps

101: 5/ck\_ps

110: 6/ck\_ps

111: 7/ck\_ps

PON duration example with LCDCLK = 32.768 kHz and PS=0x03:

000: 0  $\mu$ s

001: 244  $\mu$ s

010: 488  $\mu$ s

011: 782  $\mu$ s

100: 976  $\mu$ s

101: 1.22 ms

110: 1.46 ms

111: 1.71 ms

Bit 3 **UDDIE**: Update display done interrupt enable

This bit is set and cleared by software.

0: LCD update display done interrupt disabled

1: LCD update display done interrupt enabled

## Bit 2 Reserved, must be kept at reset value.

Bit 1 **SOFIE**: Start of frame interrupt enable

This bit is set and cleared by software.

0: LCD start-of-frame interrupt disabled

1: LCD start-of-frame interrupt enabled

Bit 0 **HD**: High drive enable

This bit is written by software to enable a low resistance divider. Displays with high internal resistance may need a longer drive time to achieve satisfactory contrast. This bit is useful in this case if some additional power consumption can be tolerated.

0: Permanent high drive disabled

1: Permanent high drive enabled. When HD = 1, PON[2:0] must be programmed to 001.

### 25.6.3 LCD status register (LCD\_SR)

Address offset: 0x08

Reset value: 0x0000 0020

| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21    | 20   | 19   | 18   | 17   | 16   |
|------|------|------|------|------|------|------|------|------|------|-------|------|------|------|------|------|
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.  | Res. | Res. | Res. | Res. | Res. |
|      |      |      |      |      |      |      |      |      |      |       |      |      |      |      |      |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5     | 4    | 3    | 2    | 1    | 0    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | FCRSF | RDY  | UDD  | UDR  | SOF  | ENS  |
|      |      |      |      |      |      |      |      |      |      | r     | r    | r    | rs   | r    | r    |

Bits 31:6 Reserved, must be kept at reset value.

Bit 5 **FCRSF**: LCD frame control register synchronization flag

This bit is set by hardware each time the LCD\_FCR register is updated in the LCDCLK domain. It is cleared by hardware when writing to the LCD\_FCR register.

- 0: LCD frame control register not yet synchronized
- 1: LCD frame control register synchronized

Bit 4 **RDY**: Ready flag

This bit is set and cleared by hardware. It indicates the status of the stepup converter.

- 0: Not ready
- 1: Stepup converter enabled and ready to provide the correct voltage

Bit 3 **UDD**: Update display done

This bit is set by hardware. It is cleared by writing 1 to UDDC in LCD\_CLR. The bit set has priority over the clear.

- 0: No event
- 1: Update display request done. A UDD interrupt is generated if UDDIE = 1 in LCD\_FCR.

*Note: If the device is in Stop mode (PCLK not provided), UDD does not generate an interrupt even if UDDIE = 1. If the display is not enabled, the UDD interrupt never occurs.*

Bit 2 **UDR**: Update display request

Each time software modifies the LCD\_RAM, it must set this bit to transfer the updated data to the second level buffer. This bit stays set until the end of the update. During this time, the LCD\_RAM is write protected.

- 0: No effect
- 1: Update display request

*Note: When the display is disabled, the update is performed for all LCD\_DISPLAY locations. When the display is enabled, the update is performed only for locations for which commons are active (depending on DUTY). For example if DUTY = 1/2, only the LCD\_DISPLAY of COM0 and COM1 are updated. Writing 0 on this bit or writing 1 when it is already 1 has no effect. This bit can be cleared by hardware only. It can be cleared only when LCDEN = 1*

Bit 1 **SOF**: Start-of-frame flag

This bit is set by hardware at the beginning of a new frame, at the same time as the display data is updated. It is cleared by writing a 1 to SOFC in LCD\_CLR. The bit clear has priority over the set.

- 0: No event
- 1: Start-of-frame event occurred. An LCD SOF interrupt is generated if SOFIE is set.

Bit 0 **ENS**: LCD enabled status

This bit is set and cleared by hardware. It indicates the LCD controller status.

- 0: LCD controller disabled
- 1: LCD controller enabled

*Note: This bit is set immediately when LCDEN in LCD\_CR goes from 0 to 1. On deactivation, it reflects the real LCD status. It becomes 0 at the end of the last displayed frame.*

## 25.6.4 LCD clear register (LCD\_CLR)

Address offset: 0x0C

Reset value: 0x0000 0000

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **UDDC**: Update display done clear

This bit is written by software to clear UDD in LCD\_SR.

0: No effect

1: Clear UDD flag.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **SOFC**: Start-of-frame flag clear

This bit is written by software to clear SOF in LCD\_SR.

0: No effect

1: Clear SOF flag.

Bit 0 Reserved, must be kept at reset value.

## 25.6.5 LCD display memory (LCD\_RAMx)

Address offset: 0x14 + 0x4 \* x, (x = 0, 2, 4, 6, 8, 10, 12, 14)

Reset value: 0x0000 0000

Refer to [Section 2.2](#) for the register boundary addresses table.

## 26 Touch sensing controller (TSC)

### 26.1 Introduction

The touch sensing controller provides a simple solution for adding capacitive sensing functionality to any application. Capacitive sensing technology is able to detect finger presence near an electrode that is protected from direct touch by a dielectric (for example glass, plastic). The capacitive variation introduced by the finger (or any conductive object) is measured using a proven implementation based on a surface charge transfer acquisition principle.

The touch sensing controller is fully supported by the STMTouch touch sensing firmware library, which is free to use and allows touch sensing functionality to be implemented reliably in the end application.

### 26.2 TSC main features

The touch sensing controller has the following main features:

- Proven and robust surface charge transfer acquisition principle
- Supports up to 24 capacitive sensing channels
- Up to 8 capacitive sensing channels can be acquired in parallel offering a very good response time
- Spread spectrum feature to improve system robustness in noisy environments
- Full hardware management of the charge transfer acquisition sequence
- Programmable charge transfer frequency
- Programmable sampling capacitor I/O pin
- Programmable channel I/O pin
- Programmable max count value to avoid long acquisition when a channel is faulty
- Dedicated end of acquisition and max count error flags with interrupt capability
- One sampling capacitor for up to 3 capacitive sensing channels to reduce the system components
- Compatible with proximity, touchkey, linear and rotary touch sensor implementation
- Designed to operate with STMTouch touch sensing firmware library

*Note:* The number of capacitive sensing channels is dependent on the size of the packages and subject to IO availability.

## 26.3 TSC functional description

### 26.3.1 TSC block diagram

The block diagram of the touch sensing controller is shown in [Figure 183](#).

Figure 183. TSC block diagram

### 26.3.2 Surface charge transfer acquisition overview

The surface charge transfer acquisition is a proven, robust and efficient way to measure a capacitance. It uses a minimum number of external components to operate with a single ended electrode type. This acquisition is designed around an analog I/O group composed of up to four GPIOs (see [Figure 184](#)). Several analog I/O groups are available to allow the acquisition of several capacitive sensing channels simultaneously and to support a larger number of capacitive sensing channels. Within a same analog I/O group, the acquisition of the capacitive sensing channels is sequential.

One of the GPIOs is dedicated to the sampling capacitor  $C_S$ . Only one sampling capacitor I/O per analog I/O group must be enabled at a time.

The remaining GPIOs are dedicated to the electrodes and are commonly called channels. For some specific needs (such as proximity detection), it is possible to simultaneously enable more than one channel per analog I/O group.

Figure 184. Surface charge transfer analog I/O group structure

MSv30930V3

**Note:**  $Gx\_IOy$  where  $x$  is the analog I/O group number and  $y$  the GPIO number within the selected group.

The surface charge transfer acquisition principle consists of charging an electrode capacitance ( $C_X$ ) and transferring a part of the accumulated charge into a sampling capacitor ( $C_S$ ). This sequence is repeated until the voltage across  $C_S$  reaches a given threshold ( $V_{IH}$  in our case). The number of charge transfers required to reach the threshold is a direct representation of the size of the electrode capacitance.

[Table 170](#) details the charge transfer acquisition sequence of the capacitive sensing channel 1. States 3 to 7 are repeated until the voltage across  $C_S$  reaches the given threshold. The same sequence applies to the acquisition of the other channels. The electrode serial resistor  $R_S$  improves the ESD immunity of the solution.

Table 170. Acquisition sequence summary

| State | Gx_IO1<br>(channel)                            | Gx_IO2<br>(sampling)                                      | Gx_IO3<br>(channel)                         | Gx_IO4<br>(channel) | State description                                         |
|-------|------------------------------------------------|-----------------------------------------------------------|---------------------------------------------|---------------------|-----------------------------------------------------------|
| #1    | Input floating<br>with analog<br>switch closed | Output open-<br>drain low with<br>analog switch<br>closed | Input floating with analog switch<br>closed |                     | Discharge all C <sub>X</sub> and<br>C <sub>S</sub>        |

| #3    | Output push-<br>pull high                      | Input floating                                            |                                             |                     | Charge C <sub>X1</sub>                                    |
| #4    | Input floating                                 |                                                           |                                             |                     | Dead time                                                 |
| #5    | Input floating with analog switch<br>closed    |                                                           | Input floating                              |                     | Charge transfer from<br>C <sub>X1</sub> to C <sub>S</sub> |
| #6    | Input floating                                 |                                                           |                                             |                     | Dead time                                                 |
| #7    | Input floating                                 |                                                           |                                             |                     | Measure C <sub>S</sub> voltage                            |

Note:  $Gx\_IOy$  where  $x$  is the analog I/O group number and  $y$  the GPIO number within the selected group.

The voltage variation over the time on the sampling capacitor  $C_S$  is detailed below (refer to [Figure 184](#) for  $V_{\text{SENSOR}}$  and  $V_{\text{CS}}$  definition):

Figure 185. Sampling capacitor voltage variation

### 26.3.3 Reset and clocks

The TSC clock source is the AHB clock (HCLK). Two programmable prescalers are used to generate the pulse generator and the spread spectrum internal clocks:

- The pulse generator clock (PGCLK) is defined using the PGPSC[2:0] bits of the TSC\_CR register
- The spread spectrum clock (SSCLK) is defined using the SSPSC bit of the TSC\_CR register

The reset and clock controller (RCC) provides dedicated bits to enable the touch sensing controller clock and to reset this peripheral. For more information, refer to [Section 6: Reset and clock control \(RCC\)](#).

### 26.3.4 Charge transfer acquisition sequence

An example of a charge transfer acquisition sequence is detailed in [Figure 186](#).

**Figure 186. Charge transfer acquisition sequence**

For higher flexibility, the charge transfer frequency is fully configurable. Both the pulse high state (charge of C<sub>x</sub>) and the pulse low state (transfer of charge from C<sub>x</sub> to C<sub>s</sub>) duration can be defined using the CTPH[3:0] and CTPL[3:0] bits in the TSC\_CR register. The standard range for the pulse high and low states duration is 500 ns to 2 μs. To ensure a correct measurement of the electrode capacitance, the pulse high state duration must be set to ensure that C<sub>x</sub> is always fully charged.

A dead time where both the sampling capacitor I/O and the channel I/O are in input floating state is inserted between the pulse high and low states to ensure an optimum charge transfer acquisition sequence. This state duration is 1 period of HCLK.

At the end of the pulse high state and if the spread spectrum feature is enabled, a variable number of periods of the SSCLK clock are added.

The reading of the sampling capacitor I/O, to determine if the voltage across  $C_S$  has reached the given threshold, is performed at the end of the pulse low state.

*Note: The following TSC control register configurations are forbidden:*

- *bits PGPSC are set to '000' and bits CTPL are set to '0001'*
- *bits PGPSC are set to '001' and bits CTPL are set to '0000'*

### 26.3.7 Sampling capacitor I/O and channel I/O mode selection

To allow the GPIOs to be controlled by the touch sensing controller, the corresponding alternate function must be enabled through the standard GPIO registers and the GPIOxAFR registers.

The GPIOs modes controlled by the TSC are defined using the TSC\_IOSCR and TSC\_IOCCR register.

When there is no ongoing acquisition, all the I/Os controlled by the touch sensing controller are in default state. While an acquisition is ongoing, only unused I/Os (neither defined as sampling capacitor I/O nor as channel I/O) are in default state. The IODEF bit in the TSC\_CR register defines the configuration of the I/Os which are in default state. The table below summarizes the configuration of the I/O depending on its mode.

**Table 172. I/O state depending on its mode and IODEF bit value**

| IODEF bit                   | Acquisition status | Unused I/O mode      | Channel I/O mode     | Sampling capacitor I/O mode |
|-----------------------------|--------------------|----------------------|----------------------|-----------------------------|
| 0<br>(output push-pull low) | No                 | Output push-pull low | Output push-pull low | Output push-pull low        |
| 0<br>(output push-pull low) | Ongoing            | Output push-pull low | -                    | -                           |
| 1<br>(input floating)       | No                 | Input floating       | Input floating       | Input floating              |
| 1<br>(input floating)       | Ongoing            | Input floating       | -                    | -                           |

#### Unused I/O mode

An unused I/O corresponds to a GPIO controlled by the TSC peripheral but not defined as an electrode I/O nor as a sampling capacitor I/O.

#### Sampling capacitor I/O mode

To allow the control of the sampling capacitor I/O by the TSC peripheral, the corresponding GPIO must be first set to alternate output open drain mode and then the corresponding Gx\_IOy bit in the TSC\_IOSCR register must be set.

Only one sampling capacitor per analog I/O group must be enabled at a time.

#### Channel I/O mode

To allow the control of the channel I/O by the TSC peripheral, the corresponding GPIO must be first set to alternate output push-pull mode and the corresponding Gx\_IOy bit in the TSC\_IOCCR register must be set.

For proximity detection where a higher equivalent electrode surface is required or to speed-up the acquisition process, it is possible to enable and simultaneously acquire several channels belonging to the same analog I/O group.

**Note:** *During the acquisition phase and even if the TSC peripheral alternate function is not enabled, as soon as the TSC\_IOSCR or TSC\_IOCCR bit is set, the corresponding GPIO analog switch is automatically controlled by the touch sensing controller.*

### 26.3.8 Acquisition mode

The touch sensing controller offers two acquisition modes:

- Normal acquisition mode: the acquisition starts as soon as the START bit in the TSC\_CR register is set.
- Synchronized acquisition mode: the acquisition is enabled by setting the START bit in the TSC\_CR register but only starts upon the detection of a falling edge or a rising edge and high level on the SYNC input pin. This mode is useful for synchronizing the capacitive sensing channels acquisition with an external signal without additional CPU load.

The GxE bits in the TSC\_I OGCSR registers specify which analog I/O groups are enabled (corresponding counter is counting). The  $C_S$  voltage of a disabled analog I/O group is not monitored and this group does not participate in the triggering of the end of acquisition flag. However, if the disabled analog I/O group contains some channels, they are pulsed.

When the  $C_S$  voltage of an enabled analog I/O group reaches the given threshold, the corresponding GxS bit of the TSC\_I OGCSR register is set. When the acquisition of all enabled analog I/O groups is complete (all GxS bits of all enabled analog I/O groups are set), the EOAF flag in the TSC\_ISR register is set. An interrupt request is generated if the EOAI E bit in the TSC\_I ER register is set.

In the case that a max count error is detected, the ongoing acquisition is stopped and both the EOAF and MCEF flags in the TSC\_ISR register are set. Interrupt requests can be generated for both events if the corresponding bits (EOAI E and MCEI E bits of the TSCI ER register) are set. Note that when the max count error is detected the remaining GxS bits in the enabled analog I/O groups are not set.

To clear the interrupt flags, the corresponding EOAI C and MCEI C bits in the TSC\_I CR register must be set.

The analog I/O group counters are cleared when a new acquisition is started. They are updated with the number of charge transfer cycles generated on the corresponding channel(s) upon the completion of the acquisition.

### 26.3.9 I/O hysteresis and analog switch control

In order to offer a higher flexibility, the touch sensing controller is able to take the control of the Schmitt trigger hysteresis and analog switch of each Gx\_I Oy. This control is available whatever the I/O control mode is (controlled by standard GPIO registers or other peripherals) assuming that the touch sensing controller is enabled. This may be useful to perform a different acquisition sequence or for other purposes.

In order to improve the system immunity, the Schmitt trigger hysteresis of the GPIOs controlled by the TSC must be disabled by resetting the corresponding Gx\_I Oy bit in the TSC\_I OHCR register.

## 26.4 TSC low-power modes

Table 173. Effect of low-power modes on TSC

| Mode            | Description                                                                                |
|-----------------|--------------------------------------------------------------------------------------------|
| Sleep           | No effect. Peripheral interrupts cause the device to exit Sleep mode.                      |
| Low power run   | No effect.                                                                                 |
| Low power sleep | No effect. Peripheral interrupts cause the device to exit Low-power sleep mode.            |
| Stop 0 / Stop 1 | Peripheral registers content is kept.                                                      |
| Stop 2          |                                                                                            |
| Standby         | Powered-down. The peripheral must be reinitialized after exiting Standby or Shutdown mode. |
| Shutdown        |                                                                                            |

## 26.5 TSC interrupts

Table 174. Interrupt control bits

| Interrupt event    | Enable control bit | Event flag | Clear flag bit | Exit the Sleep mode | Exit the Stop mode | Exit the Standby mode |
|--------------------|--------------------|------------|----------------|---------------------|--------------------|-----------------------|
| End of acquisition | EOAIE              | EOAIF      | EOAIC          | Yes                 | No                 | No                    |
| Max count error    | MCEIE              | MCEIF      | MCEIC          | Yes                 | No                 | No                    |

## 26.6 TSC registers

Refer to [Section 1.2 on page 69](#) of the reference manual for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by words (32-bit).

### 26.6.1 TSC control register (TSC\_CR)

Address offset: 0x00

Reset value: 0x0000 0000

|           |            |    |    |           |      |      |      |          |    |    |       |          |    |       |      |

Bits 31:28 **CTPH[3:0]**: Charge transfer pulse high

These bits are set and cleared by software. They define the duration of the high state of the charge transfer pulse (charge of  $C_X$ ).

0000:  $1 \times t_{PGCLK}$

0001:  $2 \times t_{PGCLK}$

...

1111:  $16 \times t_{PGCLK}$

*Note: These bits must not be modified when an acquisition is ongoing.*

Bits 27:24 **CTPL[3:0]**: Charge transfer pulse low

These bits are set and cleared by software. They define the duration of the low state of the charge transfer pulse (transfer of charge from  $C_X$  to  $C_S$ ).

0000:  $1 \times t_{PGCLK}$

0001:  $2 \times t_{PGCLK}$

...

1111:  $16 \times t_{PGCLK}$

*Note: These bits must not be modified when an acquisition is ongoing.*

*Note: Some configurations are forbidden. Refer to the [Section 26.3.4: Charge transfer acquisition sequence](#) for details.*

Bits 23:17 **SSD[6:0]**: Spread spectrum deviation

These bits are set and cleared by software. They define the spread spectrum deviation which consists in adding a variable number of periods of the SSCLK clock to the charge transfer pulse high state.

0000000:  $1 \times t_{SSCLK}$

0000001:  $2 \times t_{SSCLK}$

...

1111111:  $128 \times t_{SSCLK}$

*Note: These bits must not be modified when an acquisition is ongoing.*

Bit 16 **SSE**: Spread spectrum enable

This bit is set and cleared by software to enable/disable the spread spectrum feature.

0: Spread spectrum disabled

1: Spread spectrum enabled

*Note: This bit must not be modified when an acquisition is ongoing.*

Bit 15 **SSPSC**: Spread spectrum prescaler

This bit is set and cleared by software. It selects the AHB clock divider used to generate the spread spectrum clock (SSCLK).

0:  $f_{HCLK}$

1:  $f_{HCLK} / 2$

*Note: This bit must not be modified when an acquisition is ongoing.*

Bits 14:12 **PGPSC[2:0]**: Pulse generator prescaler

These bits are set and cleared by software. They select the AHB clock divider used to generate the pulse generator clock (PGCLK).

000:  $f_{HCLK}$   
 001:  $f_{HCLK} / 2$   
 010:  $f_{HCLK} / 4$   
 011:  $f_{HCLK} / 8$   
 100:  $f_{HCLK} / 16$   
 101:  $f_{HCLK} / 32$   
 110:  $f_{HCLK} / 64$   
 111:  $f_{HCLK} / 128$

*Note:* These bits must not be modified when an acquisition is ongoing.

*Note:* Some configurations are forbidden. Refer to the [Section 26.3.4: Charge transfer acquisition sequence](#) for details.

Bits 11:8 Reserved, must be kept at reset value.

Bits 7:5 **MCV[2:0]**: Max count value

These bits are set and cleared by software. They define the maximum number of charge transfer pulses that can be generated before a max count error is generated.

000: 255  
 001: 511  
 010: 1023  
 011: 2047  
 100: 4095  
 101: 8191  
 110: 16383  
 111: reserved

*Note:* These bits must not be modified when an acquisition is ongoing.

Bit 4 **IODEF**: I/O Default mode

This bit is set and cleared by software. It defines the configuration of all the TSC I/Os when there is no ongoing acquisition. When there is an ongoing acquisition, it defines the configuration of all unused I/Os (not defined as sampling capacitor I/O or as channel I/O).

0: I/Os are forced to output push-pull low  
 1: I/Os are in input floating

*Note:* This bit must not be modified when an acquisition is ongoing.

Bit 3 **SYNCPOL**: Synchronization pin polarity

This bit is set and cleared by software to select the polarity of the synchronization input pin.

0: Falling edge only  
 1: Rising edge and high level

Bit 2 **AM**: Acquisition mode

This bit is set and cleared by software to select the acquisition mode.

0: Normal acquisition mode (acquisition starts as soon as START bit is set)

1: Synchronized acquisition mode (acquisition starts if START bit is set and when the selected signal is detected on the SYNC input pin)

*Note: This bit must not be modified when an acquisition is ongoing.*

Bit 1 **START**: Start a new acquisition

This bit is set by software to start a new acquisition. It is cleared by hardware as soon as the acquisition is complete or by software to cancel the ongoing acquisition.

0: Acquisition not started

1: Start a new acquisition

Bit 0 **TSCE**: Touch sensing controller enable

This bit is set and cleared by software to enable/disable the touch sensing controller.

0: Touch sensing controller disabled

1: Touch sensing controller enabled

*Note: When the touch sensing controller is disabled, TSC registers settings have no effect.*

## 26.6.2 TSC interrupt enable register (TSC\_IER)

Address offset: 0x04

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |      |      |      |      |      |       |       |

|      |      |      |      |      |      |      |      |      |      |      |      |      |      | rw    | rw    |

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **MCEIE**: Max count error interrupt enable

This bit is set and cleared by software to enable/disable the max count error interrupt.

0: Max count error interrupt disabled

1: Max count error interrupt enabled

Bit 0 **EOAIE**: End of acquisition interrupt enable

This bit is set and cleared by software to enable/disable the end of acquisition interrupt.

0: End of acquisition interrupt disabled

1: End of acquisition interrupt enabled

### 26.6.3 TSC interrupt clear register (TSC\_ICR)

Address offset: 0x08

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |      |      |      |      |      |       |       |
|------|------|------|------|------|------|------|------|------|------|------|------|------|------|-------|-------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17    | 16    |

|      |      |      |      |      |      |      |      |      |      |      |      |      |      |       |       |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1     | 0     |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | MCEIC | EOAIC |
|      |      |      |      |      |      |      |      |      |      |      |      |      |      | rw    | rw    |

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **MCEIC**: Max count error interrupt clear

This bit is set by software to clear the max count error flag and it is cleared by hardware when the flag is reset. Writing a '0' has no effect.

0: No effect

1: Clears the corresponding MCEF of the TSC\_ISR register

Bit 0 **EOAIC**: End of acquisition interrupt clear

This bit is set by software to clear the end of acquisition flag and it is cleared by hardware when the flag is reset. Writing a '0' has no effect.

0: No effect

1: Clears the corresponding EOAF of the TSC\_ISR register

### 26.6.4 TSC interrupt status register (TSC\_ISR)

Address offset: 0x0C

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |

|      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | MCEF | EOAF |
|      |      |      |      |      |      |      |      |      |      |      |      |      |      | r    | r    |

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **MCEF**: Max count error flag

This bit is set by hardware as soon as an analog I/O group counter reaches the max count value specified. It is cleared by software writing 1 to the bit MCEIC of the TSC\_ICR register.

0: No max count error (MCE) detected

1: Max count error (MCE) detected

Bit 0 **EOAF**: End of acquisition flag

This bit is set by hardware when the acquisition of all enabled group is complete (all GxS bits of all enabled analog I/O groups are set or when a max count error is detected). It is cleared by software writing 1 to the bit EOAIC of the TSC\_ICR register.

0: Acquisition is ongoing or not started

1: Acquisition is complete

## 26.6.5 TSC I/O hysteresis control register (TSC\_IOHCR)

Address offset: 0x10

Reset value: 0xFFFF FFFF

|        |        |        |        |        |        |        |        |        |        |        |        |        |        |        |        |
|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|
| 31     | 30     | 29     | 28     | 27     | 26     | 25     | 24     | 23     | 22     | 21     | 20     | 19     | 18     | 17     | 16     |
| G8_IO4 | G8_IO3 | G8_IO2 | G8_IO1 | G7_IO4 | G7_IO3 | G7_IO2 | G7_IO1 | G6_IO4 | G6_IO3 | G6_IO2 | G6_IO1 | G5_IO4 | G5_IO3 | G5_IO2 | G5_IO1 |
| rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     |
| 15     | 14     | 13     | 12     | 11     | 10     | 9      | 8      | 7      | 6      | 5      | 4      | 3      | 2      | 1      | 0      |
| G4_IO4 | G4_IO3 | G4_IO2 | G4_IO1 | G3_IO4 | G3_IO3 | G3_IO2 | G3_IO1 | G2_IO4 | G2_IO3 | G2_IO2 | G2_IO1 | G1_IO4 | G1_IO3 | G1_IO2 | G1_IO1 |
| rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     |

Bits 31:0 **Gx\_IOy**: Gx\_IOy Schmitt trigger hysteresis mode

These bits are set and cleared by software to enable/disable the Gx\_IOy Schmitt trigger hysteresis.

0: Gx\_IOy Schmitt trigger hysteresis disabled

1: Gx\_IOy Schmitt trigger hysteresis enabled

*Note: These bits control the I/O Schmitt trigger hysteresis whatever the I/O control mode is (even if controlled by standard GPIO registers).*

## 26.6.6 TSC I/O analog switch control register (TSC\_IOASCR)

Address offset: 0x18

Reset value: 0x0000 0000

|        |        |        |        |        |        |        |        |        |        |        |        |        |        |        |        |
|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|
| 31     | 30     | 29     | 28     | 27     | 26     | 25     | 24     | 23     | 22     | 21     | 20     | 19     | 18     | 17     | 16     |
| G8_IO4 | G8_IO3 | G8_IO2 | G8_IO1 | G7_IO4 | G7_IO3 | G7_IO2 | G7_IO1 | G6_IO4 | G6_IO3 | G6_IO2 | G6_IO1 | G5_IO4 | G5_IO3 | G5_IO2 | G5_IO1 |
| rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     |
| 15     | 14     | 13     | 12     | 11     | 10     | 9      | 8      | 7      | 6      | 5      | 4      | 3      | 2      | 1      | 0      |
| G4_IO4 | G4_IO3 | G4_IO2 | G4_IO1 | G3_IO4 | G3_IO3 | G3_IO2 | G3_IO1 | G2_IO4 | G2_IO3 | G2_IO2 | G2_IO1 | G1_IO4 | G1_IO3 | G1_IO2 | G1_IO1 |
| rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     |

Bits 31:0 **Gx\_IOy**: Gx\_IOy analog switch enable

These bits are set and cleared by software to enable/disable the Gx\_IOy analog switch.

0: Gx\_IOy analog switch disabled (opened)

1: Gx\_IOy analog switch enabled (closed)

*Note: These bits control the I/O analog switch whatever the I/O control mode is (even if controlled by standard GPIO registers).*

## 26.6.7 TSC I/O sampling control register (TSC\_IOSCR)

Address offset: 0x20

Reset value: 0x0000 0000

|        |        |        |        |        |        |        |        |        |        |        |        |        |        |        |        |
|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|
| 31     | 30     | 29     | 28     | 27     | 26     | 25     | 24     | 23     | 22     | 21     | 20     | 19     | 18     | 17     | 16     |
| G8_IO4 | G8_IO3 | G8_IO2 | G8_IO1 | G7_IO4 | G7_IO3 | G7_IO2 | G7_IO1 | G6_IO4 | G6_IO3 | G6_IO2 | G6_IO1 | G5_IO4 | G5_IO3 | G5_IO2 | G5_IO1 |
| rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     |
| 15     | 14     | 13     | 12     | 11     | 10     | 9      | 8      | 7      | 6      | 5      | 4      | 3      | 2      | 1      | 0      |
| G4_IO4 | G4_IO3 | G4_IO2 | G4_IO1 | G3_IO4 | G3_IO3 | G3_IO2 | G3_IO1 | G2_IO4 | G2_IO3 | G2_IO2 | G2_IO1 | G1_IO4 | G1_IO3 | G1_IO2 | G1_IO1 |
| rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     |

Bits 31:0 **Gx\_IOy**: Gx\_IOy sampling mode

These bits are set and cleared by software to configure the Gx\_IOy as a sampling capacitor I/O. Only one I/O per analog I/O group must be defined as sampling capacitor.

0: Gx\_IOy unused

1: Gx\_IOy used as sampling capacitor

*Note: These bits must not be modified when an acquisition is ongoing.*

*During the acquisition phase and even if the TSC peripheral alternate function is not enabled, as soon as the TSC\_IOSCR bit is set, the corresponding GPIO analog switch is automatically controlled by the touch sensing controller.*

## 26.6.8 TSC I/O channel control register (TSC\_IOCOCR)

Address offset: 0x28

Reset value: 0x0000 0000

|        |        |        |        |        |        |        |        |        |        |        |        |        |        |        |        |
|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|
| 31     | 30     | 29     | 28     | 27     | 26     | 25     | 24     | 23     | 22     | 21     | 20     | 19     | 18     | 17     | 16     |

Bits 31:0 **Gx\_IOy**: Gx\_IOy channel mode

These bits are set and cleared by software to configure the Gx\_IOy as a channel I/O.

0: Gx\_IOy unused

1: Gx\_IOy used as channel

*Note: These bits must not be modified when an acquisition is ongoing.*

*During the acquisition phase and even if the TSC peripheral alternate function is not enabled, as soon as the TSC\_IOCOCR bit is set, the corresponding GPIO analog switch is automatically controlled by the touch sensing controller.*

## 26.6.9 TSC I/O group control status register (TSC\_I OGCSR)

Address offset: 0x30

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |     |     |     |     |     |     |     |     |

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **GxS**: Analog I/O group x status

These bits are set by hardware when the acquisition on the corresponding enabled analog I/O group x is complete. They are cleared by hardware when a new acquisition is started.

0: Acquisition on analog I/O group x is ongoing or not started

1: Acquisition on analog I/O group x is complete

*Note: When a max count error is detected the remaining GxS bits of the enabled analog I/O groups are not set.*

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **GxE**: Analog I/O group x enable

These bits are set and cleared by software to enable/disable the acquisition (counter is counting) on the corresponding analog I/O group x.

0: Acquisition on analog I/O group x disabled

1: Acquisition on analog I/O group x enabled

## 26.6.10 TSC I/O group x counter register (TSC\_I OGxCR)

x represents the analog I/O group number.

Address offset: 0x30 + 0x04 \* x, (x = 1 to 8)

Reset value: 0x0000 0000

Bits 31:14 Reserved, must be kept at reset value.

Bits 13:0 **CNT[13:0]**: Counter value

These bits represent the number of charge transfer cycles generated on the analog I/O group x to complete its acquisition (voltage across  $C_S$  has reached the threshold).

## 26.6.11 TSC register map

Table 175. TSC register map and reset values

| Offset | Register    | 31        | 30     | 29     | 28     | 27        | 26     | 25     | 24     | 23       | 22     | 21     | 20     | 19     | 18     | 17     | 16     | 15     | 14     | 13        | 12         | 11     | 10     | 9      | 8      | 7      | 6         | 5      | 4      | 3      | 2       | 1      | 0      |      |

Refer to [Section 2.2 on page 75](#) for the register boundary addresses.

## 27 True random number generator (RNG)

### 27.1 Introduction

The RNG is a true random number generator that continuously provides 32-bit entropy samples, based on an analog noise source. It can be used by the application as a live entropy source to build a NIST compliant deterministic random bit generator (DRBG).

The RNG true random number generator has been tested using NIST statistical test suite SP800-22 rev1a (April 2010).

### 27.2 RNG main features

- The RNG delivers 32-bit true random numbers, produced by an analog entropy source post-processed with linear-feedback shift registers (LFSR).
- In the NIST configuration, it produces one 32-bit random samples every 42 RNG clock cycles(dedicated clock).
- It allows embedded continuous basic health tests with associated error management
  - Includes too low sampling clock detection and repetition count tests.
- It can be disabled to reduce power consumption.
- It has an AMBA AHB slave peripheral, accessible through 32-bit word single accesses only (else an AHB bus error is generated). Warning! any write not equal to 32 bits might corrupt the register content.

## 27.3 RNG functional description

### 27.3.1 RNG block diagram

Figure 188 shows the RNG block diagram.

Figure 188. RNG block diagram

### 27.3.2 RNG internal signals

Table 176 describes a list of useful-to-know internal signals available at the RNG level, not at the STM32 product level (on pads).

Table 176. RNG internal input/output signals

| Signal name | Signal type    | Description                                   |
|-------------|----------------|-----------------------------------------------|
| rng_it      | Digital output | RNG global interrupt request                  |
| rng_hclk    | Digital input  | AHB clock                                     |
| rng_clk     | Digital input  | RNG dedicated clock, asynchronous to rng_hclk |

### 27.3.3 Random number generation

The true random number generator (RNG) delivers truly random data through its AHB interface at deterministic intervals. Within its boundary the RNG implements the entropy source model pictured on [Figure 189](#), and provides three main functions to the application:

- Collects the bitstring output of the entropy source box
- Obtains samples of the noise source for validation purpose
- Collects error messages from continuous health tests

**Figure 189. Entropy source model**

The main components of the RNG are:

- A source of physical randomness (analog noise source)
- A digitization stage for this analog noise source
- A stage delivering post-processed noise source (raw data)
- An output buffer for the raw data. If further cryptographic conditioning is required by the application it needs to be performed by software.
- An optional output for the digitized noise source (unbuffered, on digital pads)
- Basic health tests on the digitized noise source

The components pictured above are detailed hereafter.

### Noise source

The noise source is the component that contains the non-deterministic, entropy-providing activity that is ultimately responsible for the uncertainty associated with the bitstring output by the entropy source. It is composed of:

- Two analog noise sources, each based on three XORed free-running ring oscillator outputs. It is possible to disable those analog oscillators to save power, as described in [Section 27.3.8: RNG low-power use](#).
- A sampling stage of these outputs clocked by a dedicated clock input (rng\_clk), delivering a 2-bit raw data output.

This noise source sampling is independent to the AHB interface clock frequency (rng\_hclk).

*Note:* In [Section 27.6: RNG entropy source validation](#) the recommended RNG clock frequencies are given.

### Post processing

The sample values obtained from a true random noise source consist of 2-bit bitstrings. Because this noise source output is biased, the RNG implements a post-processing component that reduces that bias to a tolerable level.

The RNG post-processing consists of two stages, applied to each noise source bits:

- The RNG takes half of the bits from the sampled noise source, and half of the bits from inverted sampled noise source. Thus, if the source generates more '1' than '0' (or the opposite), it is filtered
- A linear feedback shift register (LFSR) performs a whitening process, producing 8-bit strings.

This component is clocked by the RNG clock.

The times required between two random number generations, and between the RNG initialization and availability of first sample are described in [Section 27.5: RNG processing time](#).

### Output buffer

The RNG\_DR data output register can store up to two 16-bit words, which have been output from the post-processing component (LFSR). In order to read back 32-bit random samples, it is required to wait 42 RNG clock cycles.

Whenever a random number is available through the RNG\_DR register, the DRDY flag changes from 0 to 1. This flag remains high until the output buffer becomes empty after reading one word from the RNG\_DR register.

*Note:* When interrupts are enabled an interrupt is generated when this data ready flag transitions from 0 to 1. Interrupt is then cleared automatically by the RNG as explained above.

### Health checks

This component ensures that the entire entropy source (with its noise source) starts then operates as expected, obtaining assurance that failures are caught quickly and with a high probability and reliability.

The RNG implements the following health check features.

1. Continuous health tests, running indefinitely on the output of the noise source
  - Repetition count test, flagging an error when:
    - a) One of the noise source has provided more than 64 consecutive bits at a constant value ("0" or "1")
    - b) One of the noise sources has delivered more than 32 consecutive occurrence of two bits patterns ("01" or "10")
2. Vendor specific continuous test
  - Real-time "too slow" sampling clock detector, flagging an error when one RNG clock cycle is smaller than AHB clock cycle divided by 16.

The CECS and SECS status bits in the RNG\_SR register indicate when an error condition is detected, as detailed in [Section 27.3.7: Error management](#).

*Note:* An interrupt can be generated when an error is detected.

### 27.3.4 RNG initialization

When a hardware reset occurs the following chain of events occurs:

1. The analog noise source is enabled, and the logic starts sampling the analog output after four RNG clock cycles, filling LFSR shift register and associated 16-bit post-processing shift register.
2. The output buffer is refilled automatically according to the RNG usage.

The associated initialization time can be found in [Section 27.5: RNG processing time](#).

### 27.3.5 RNG operation

#### Normal operations

To run the RNG using interrupts, the following steps are recommended:

1. Enable the interrupts by setting the IE bit in the RNG\_CR register. At the same time, enable the RNG by setting the bit RNGEN=1.
2. An interrupt is now generated when a random number is ready or when an error occurs. Therefore, at each interrupt, check that:
  - No error occurred. The SEIS and CEIS bits must be set to 0 in the RNG\_SR register.
  - A random number is ready. The DRDY bit must be set to 1 in the RNG\_SR register.
  - If the above two conditions are true the content of the RNG\_DR register can be read.

To run the RNG in polling mode following steps are recommended:

1. Enable the random number generation by setting the RNGEN bit to “1” in the RNG\_CR register.
2. Read the RNG\_SR register and check that:
  - No error occurred (the SEIS and CEIS bits must be set to 0)
  - A random number is ready (the DRDY bit must be set to 1)
3. If above conditions are true read the content of the RNG\_DR register.

**Note:** *When data is not ready (DRDY = 0) RNG\_DR returns zero. It is recommended to always verify that RNG\_DR is different from zero. Because when it is the case a seed error occurred between RNG\_SR polling and RNG\_DR output reading (rare event).*

### Low-power operations

If the power consumption is a concern to the application, low-power strategies can be used, as described in [Section 27.3.8: RNG low-power use](#).

### Software post-processing

If a NIST approved DRBG with 128 bits of security strength is required an approved random generator software must be built around the RNG true random number generator.

## 27.3.6 RNG clocking

The RNG runs on two different clocks: the AHB bus clock and a dedicated RNG clock.

The AHB clock is used to clock the AHB banked registers and the post-processing component. The RNG clock is used for noise source sampling. Recommended clock configurations are detailed in [Section 27.6: RNG entropy source validation](#).

**Note:** *When the CED bit in the RNG\_CR register is set to 0, the RNG clock frequency the **must be higher** than the AHB clock frequency divided by 16, otherwise the clock checker always flags a clock error (CECS = 1 in the RNG\_SR register).*

See [Section 27.3.1: RNG block diagram](#) for details (AHB and RNG clock domains).

## 27.3.7 Error management

In parallel to random number generation a health check block verifies the correct noise source behavior and the frequency of the RNG source clock as detailed in this section. Associated error state is also described.

### Clock error detection

When the clock error detection is enabled (CED = 0) and if the RNG clock frequency is too low, the RNG sets to 1 both the CEIS and CECS bits to indicate that a clock error occurred. In this case, the application must check that the RNG clock is configured correctly (see [Section 27.3.6: RNG clocking](#)) and then it must clear the CEIS bit interrupt flag. The CECS bit is automatically cleared when the clocking condition is normal.

**Note:** *The clock error has no impact on generated random numbers that is the application can still read the RNG\_DR register.*

*CEIS is set only when CECS is set to 1 by RNG.*

### Noise source error detection

When a noise source (or seed) error occurs, the RNG stops generating random numbers and sets to 1 both SEIS and SECS bits to indicate that a seed error occurred. If a value is available in the RNG\_DR register, it must not be used as it may not have enough entropy.

In order to fully recover from a seed error application must clear the SEIS bit by writing it to “0”, then clear and set the RNGEN bit to reinitialize and restart the RNG.

### 27.3.8 RNG low-power use

If power consumption is a concern, the RNG can be disabled as soon as the DRDY bit is set to “1” by setting the RNGEN bit to “0” in the RNG\_CR register. The 32-bit random value stored in the RNG\_DR register is still available. If a new random is needed the application needs to re-enable the RNG and wait for 42+4 RNG clock cycles.

When disabling the RNG the user deactivates all the analog seed generators, whose power consumption is given in the datasheet electrical characteristics section.

## 27.4 RNG interrupts

In the RNG an interrupt can be produced on the following events:

- Data ready flag
- Seed error, see [Section 27.3.7: Error management](#)
- Clock error, see [Section 27.3.7: Error management](#)

Dedicated interrupt enable control bits are available as shown in [Table 177](#).

**Table 177. RNG interrupt requests**

| Interrupt acronym | Interrupt event  | Event flag | Enable control bit | Interrupt clear method |
|-------------------|------------------|------------|--------------------|------------------------|
| RNG               | Data ready flag  | DRDY       | IE                 | None (automatic)       |
|                   | Seed error flag  | SEIS       | IE                 | Write 0 to SEIS        |
|                   | Clock error flag | CEIS       | IE                 | Write 0 to CEIS        |

The user can enable or disable the above interrupt sources individually by changing the mask bits or the general interrupt control bit IE in the RNG\_CR register. The status of the individual interrupt sources can be read from the RNG\_SR register.

*Note:* Interrupts are generated only when RNG is enabled.

### 27.5 RNG processing time

The RNG can produce one 32-bit random numbers every 42 RNG clock cycles.

After enabling or re-enabling the RNG using the RNGEN bit, it takes 46 RNG clock cycles before random data are available.

## 27.6 RNG entropy source validation

### 27.6.1 Introduction

In order to assess the amount of entropy available from the RNG, STMicroelectronics has tested the peripheral using NIST SP800-22 rev1a statistical tests. The results can be provided on demand or the customer can reproduce the tests.

For more information on running this NIST statistical test suite, refer to *STM32 microcontrollers random number generation validation using NIST statistical test suite* application note (AN4230), available on STMicroelectronics website.

### 27.6.2 Validation conditions

STMicroelectronics has tested the RNG true random number generator in the following conditions:

- RNG clock rng\_clk= 48 MHz (CED bit = '0' in RNG\_CR register) and rng\_clk = 400 kHz (CED bit = '1' in RNG\_CR register).

### 27.6.3 Data collection

In order to run statistical tests, it is required to collect samples from the entropy source at the raw data level as well as at the output of the entropy source. Contact STMicroelectronics if the above samples need to be retrieved for the product.

## 27.7 RNG registers

The RNG is associated with a control register, a data register and a status register.

### 27.7.1 RNG control register (RNG\_CR)

|      |      |      |      |      |      |      |      |      |      | rw   |      | rw   | rw    |      |      |

Bits 31:6 Reserved, must be kept at reset value.

Bit 5 **CED**: Clock error detection

0: Clock error detection enabled

1: Clock error detection is disabled

The clock error detection cannot be enabled nor disabled on-the-fly when the RNG is enabled, that is to enable or disable CED, the RNG must be disabled.

Bit 4 Reserved, must be kept at reset value.

Bit 3 **IE**: Interrupt enable

0: RNG interrupt is disabled

1: RNG interrupt is enabled. An interrupt is pending as soon as the DRDY, SEIS, or CEIS is set in the RNG\_SR register.

Bit 2 **RNGEN**: True random number generator enable

0: True random number generator is disabled. Analog noise sources are powered off and logic clocked by the RNG clock is gated.

1: True random number generator is enabled.

Bits 1:0 Reserved, must be kept at reset value.

## 27.7.2 RNG status register (RNG\_SR)

Address offset: 0x004

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |       |       |      |      |      |      |      |
|------|------|------|------|------|------|------|------|------|-------|-------|------|------|------|------|------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22    | 21    | 20   | 19   | 18   | 17   | 16   |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.  | Res.  | Res. | Res. | Res. | Res. | Res. |
|      |      |      |      |      |      |      |      |      |       |       |      |      |      |      |      |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6     | 5     | 4    | 3    | 2    | 1    | 0    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | SEIS  | CEIS  | Res. | Res. | SECS | CECS | DRDY |
|      |      |      |      |      |      |      |      |      | rc_w0 | rc_w0 |      |      | r    | r    | r    |

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **SEIS**: Seed error interrupt status

This bit is set at the same time as SECS. It is cleared by writing 0. Writing 1 has no effect.

0: No faulty sequence detected

1: At least one faulty sequence is detected. See SECS bit description for details.

An interrupt is pending if IE = 1 in the RNG\_CR register.

Bit 5 **CEIS**: Clock error interrupt status

This bit is set at the same time as CECS. It is cleared by writing 0. Writing 1 has no effect.

0: The RNG clock is correct ( $f_{\text{RNGCLK}} > f_{\text{HCLK}}/16$ )

1: The RNG is detected too slow ( $f_{\text{RNGCLK}} < f_{\text{HCLK}}/16$ )

An interrupt is pending if IE = 1 in the RNG\_CR register.

Bits 4:3 Reserved, must be kept at reset value.

Bit 2 **SECS**: Seed error current status

0: No faulty sequence has currently been detected. If the SEIS bit is set, this means that a faulty sequence was detected and the situation has been recovered.

1: One of the noise sources has provided more than 64 consecutive bits at a constant value ("0" or "1"), or more than 32 consecutive occurrence of two bits patterns ("01" or "10")

Bit 1 **CECS**: Clock error current status

0: The RNG clock is correct ( $f_{\text{RNGCLK}} > f_{\text{HCLK}}/16$ ). If the CEIS bit is set, this means that a slow clock was detected and the situation has been recovered.

1: The RNG clock is too slow ( $f_{\text{RNGCLK}} < f_{\text{HCLK}}/16$ ).

*Note: CECS bit is valid only if the CED bit in the RNG\_CR register is set to 0.*

Bit 0 **DRDY**: Data ready

0: The RNG\_DR register is not yet valid, no random data is available.

1: The RNG\_DR register contains valid random data.

Once the RNG\_DR register has been read, this bit returns to 0 until a new random value is generated.

If IE=1 in the RNG\_CR register, an interrupt is generated when DRDY = 1.

### 27.7.3 RNG data register (RNG\_DR)

Address offset: 0x008

Reset value: 0x0000 0000

The RNG\_DR register is a read-only register that delivers a 32-bit random value when read. After being read, this register delivers a new random value after 42 periods of RNG clock if the output FIFO is empty.

The content of this register is valid when the DRDY = 1 and the value is not 0x0, even if RNGEN = 0.

|               |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|---------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31            | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| RNDATA[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| r             | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  |
| 15            | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| RNDATA[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| r             | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  |

Bits 31:0 **RNDATA[31:0]**: Random data

32-bit random data, which are valid when DRDY = 1. When DRDY = 0, the RNDATA value is zero.

When DRDY is set, it is recommended to always verify that RNG\_DR is different from zero. The zero value means that a seed error occurred between RNG\_SR polling and RND\_DR output reading (a rare event).

### 27.7.4 RNG register map

Table 178. RNG register map and reset map

| Offset | Register name | 31           | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   | 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |

|        | Reset value   |              |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| 0x008  | RNG_DR        | RNDATA[31:0] |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|        | Reset value   | 0            | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    |

Refer to [Section 2.2: Memory organization](#) for the register boundary addresses.

## 28 AES hardware accelerator (AES)

This section applies to STM32L486/L4A6 devices only.

### 28.1 Introduction

The AES hardware accelerator (AES) encrypts or decrypts data, using an algorithm and implementation fully compliant with the advanced encryption standard (AES) defined in Federal information processing standards (FIPS) publication 197.

Multiple chaining modes are supported (ECB, CBC, CTR, GCM, GMAC, CCM), for key sizes of 128 or 256 bits.

The AES accelerator is a 32-bit AHB peripheral. It supports DMA single transfers for incoming and outgoing data (two DMA channels required).

The AES peripheral provides hardware acceleration to AES cryptographic algorithms packaged in STM32 cryptographic library.

AES is an AMBA AHB slave peripheral, accessible through 32-bit word single accesses only (otherwise an AHB bus error is generated and write accesses are ignored).

### 28.2 AES main features

- Compliance with NIST “*Advanced encryption standard (AES), FIPS publication 197*” from November 2001
- 128-bit data block processing
- Support for cipher key lengths of 128-bit and 256-bit
- Encryption and decryption with multiple chaining modes:
  - Electronic codebook (ECB) mode
  - Cipher block chaining (CBC) mode
  - Counter (CTR) mode
  - Galois counter mode (GCM)
  - Galois message authentication code (GMAC) mode
  - Counter with CBC-MAC (CCM) mode
- 51 or 75 clock cycle latency in ECB mode for processing one 128-bit block of data with, respectively, 128-bit or 256-bit key
- Integrated key scheduler with its key derivation stage (ECB or CBC decryption only)
- AMBA AHB slave peripheral, accessible through 32-bit word single accesses only
- 256-bit register for storing the cryptographic key (eight 32-bit registers)
- 128-bit register for storing initialization vector (four 32-bit registers)
- 32-bit buffer for data input and output
- Automatic data flow control with support of single-transfer direct memory access (DMA) using two channels (one for incoming data, one for processed data)
- Data-swapping logic to support 1-, 8-, 16- or 32-bit data
- Possibility for software to suspend a message if AES needs to process another message with a higher priority, then resume the original message

## 28.3 AES implementation

The device has a single instance of AES peripheral.

## 28.4 AES functional description

### 28.4.1 AES block diagram

Figure 190 shows the block diagram of AES.

Figure 190. AES block diagram

### 28.4.2 AES internal signals

Table 179 describes the user relevant internal signals interfacing the AES peripheral.

Table 179. AES internal input/output signals

| Signal name | Signal type          | Description                           |
|-------------|----------------------|---------------------------------------|
| aes_hclk    | digital input        | AHB bus clock                         |
| aes_it      | digital output       | AES interrupt request                 |
| aes_in_dma  | digital input/output | Input DMA single request/acknowledge  |
| aes_out_dma | digital input/output | Output DMA single request/acknowledge |

### 28.4.3 AES cryptographic core

#### Overview

The AES cryptographic core consists of the following components:

- AES algorithm (AEA)
- multiplier over a binary Galois field (GF2mul)
- key input
- initialization vector (IV) input
- chaining algorithm logic (XOR, feedback/counter, mask)

The AES core works on 128-bit data blocks (four words) with 128-bit or 256-bit key length. Depending on the chaining mode, the AES requires zero or one 96-bit initialization vector IV (and a 32-bit counter field).

The AES features the following modes of operation:

- **Mode 1:**  
Plaintext encryption using a key stored in the AES\_KEYRx registers
- **Mode 2:**  
ECB or CBC decryption key preparation. It must be used prior to selecting Mode 3 with ECB or CBC chaining modes. The key prepared for decryption is stored automatically in the AES\_KEYRx registers. Now the AES peripheral is ready to switch to Mode 3 for executing data decryption.
- **Mode 3:**  
Ciphertext decryption using a key stored in the AES\_KEYRx registers. When ECB and CBC chaining modes are selected, the key must be prepared beforehand, through Mode 2.
- **Mode 4:**  
ECB or CBC ciphertext single decryption using the key stored in the AES\_KEYRx registers (the initial key is derived automatically).

*Note: Mode 2 and mode 4 are only used when performing ECB and CBC decryption. When Mode 4 is selected only one decryption can be done, therefore usage of Mode 2 and Mode 3 is recommended instead.*

The operating mode is selected by programming the MODE[1:0] bitfield of the AES\_CR register. It may be done only when the AES peripheral is disabled.

#### Typical data processing

Typical usage of the AES is described in [Section 28.4.4: AES procedure to perform a cipher operation on page 828](#).

*Note: The outputs of the intermediate AEA stages are never revealed outside the cryptographic boundary, with the exclusion of the IVI bitfield.*

## Chaining modes

The following chaining modes are supported by AES, selected through the CHMOD[2:0] bitfield of the AES\_CR register:

- Electronic code book (ECB)
- Cipher block chaining (CBC)
- Counter (CTR)
- Galois counter mode (GCM)
- Galois message authentication code (GMAC)
- Counter with CBC-MAC (CCM)

**Note:** *The chaining mode may be changed only when AES is disabled (bit EN of the AES\_CR register set).*

Principle of each AES chaining mode is provided in the following subsections.

Detailed information is in dedicated sections, starting from [Section 28.4.8: AES basic chaining modes \(ECB, CBC\)](#).

## Electronic codebook (ECB) mode

**Figure 191. ECB encryption and decryption principle**

ECB is the simplest mode of operation. There are no chaining operations, and no special initialization stage. The message is divided into blocks and each block is encrypted or decrypted separately.

**Note:** *For decryption, a special key scheduling is required before processing the first block.*

## Cipher block chaining (CBC) mode

Figure 192. CBC encryption and decryption principle

In CBC mode the output of each block chains with the input of the following block. To make each message unique, an initialization vector is used during the first block processing.

*Note:* For decryption, a special key scheduling is required before processing the first block.

## Counter (CTR) mode

Figure 193. CTR encryption and decryption principle

The CTR mode uses the AES core to generate a key stream. The keys are then XORed with the plaintext to obtain the ciphertext as specified in NIST *Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation*.

**Note:** Unlike with ECB and CBC modes, no key scheduling is required for the CTR decryption, since in this chaining scheme the AES core is always used in encryption mode for producing the key stream, or counter blocks.

## Galois/counter mode (GCM)

Figure 194. GCM encryption and authentication principle

In Galois/counter mode (GCM), the plaintext message is encrypted while a message authentication code (MAC) is computed in parallel, thus generating the corresponding ciphertext and its MAC (also known as authentication tag). It is defined in NIST *Special Publication 800-38D, Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC*.

GCM mode is based on AES in counter mode for confidentiality. It uses a multiplier over a fixed finite field for computing the message authentication code. It requires an initial value and a particular 128-bit block at the end of the message.

## Galois message authentication code (GMAC) principle

Figure 195. GMAC authentication principle

Galois message authentication code (GMAC) allows authenticating a message and generating the corresponding message authentication code (MAC). It is defined in NIST *Special Publication 800-38D, Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC*.

GMAC is similar to GCM, except that it is applied on a message composed only by plaintext authenticated data (that is, only header, no payload).

### Counter with CBC-MAC (CCM) principle

**Figure 196. CCM encryption and authentication principle**

In Counter with cipher block chaining-message authentication code (CCM) mode, the plaintext message is encrypted while a message authentication code (MAC) is computed in parallel, thus generating the corresponding ciphertext and the corresponding MAC (also known as tag). It is described by NIST in *Special Publication 800-38C, Recommendation for Block Cipher Modes of Operation - The CCM Mode for Authentication and Confidentiality*.

CCM mode is based on AES in counter mode for confidentiality and it uses CBC for computing the message authentication code. It requires an initial value.

Like GCM, the CCM chaining mode can be applied on a message composed only by plaintext authenticated data (that is, only header, no payload). Note that this way of using CCM is not called CMAC (it is not similar to GCM/GMAC), and its usage is not recommended by NIST.

## 28.4.4 AES procedure to perform a cipher operation

### Introduction

A typical cipher operation is explained below. Detailed information is provided in sections starting from [Section 28.4.8: AES basic chaining modes \(ECB, CBC\)](#).

The flowcharts shown in [Figure 197](#) and [Figure 198](#) describe the way STM32 cryptographic library implements the AES algorithm. AES accelerates the execution of the AES-128 and AES-256 cryptographic algorithms in ECB, CBC, CTR, CCM, and GCM operating modes.

**Note:** For more details on the cryptographic library, refer to the UM1924 user manual “STM32 crypto library” available from [www.st.com](http://www.st.com).

Figure 197. STM32 cryptolib AES flowchart examples

Figure 198. STM32 cryptolib AES flowchart examples (continued)

### Initialization of AES

To initialize AES, first disable it by clearing the EN bit of the AES\_CR register. Then perform the following steps in any order:

- Configure the AES mode, by programming the MODE[1:0] bitfield of the AES\_CR register.
  - For encryption, Mode 1 must be selected (MODE[1:0] = 00).
  - For decryption, Mode 3 must be selected (MODE[1:0] = 10), unless ECB or CBC chaining modes are used. In this latter case, an initial key derivation of the encryption key must be performed, as described in [Section 28.4.5: AES decryption key preparation](#).
- Select the chaining mode, by programming the CHMOD[2:0] bitfield of the AES\_CR register
- Configure the key size (128-bit or 256-bit), with the KEYSIZE bitfield of the AES\_CR register.
- Write a symmetric key into the AES\_KEYRx registers (4 or 8 registers depending on the key size).
- Configure the data type (1-, 8-, 16- or 32-bit), with the DATATYPE[1:0] bitfield in the AES\_CR register.
- When it is required (for example in CBC or CTR chaining modes), write the initialization vectors into the AES\_IVRx register.

## Data append

This section describes different ways of appending data for processing, where the size of data to process is not a multiple of 128 bits.

For ECB, CBC and GCM encryption mode, refer to [Section 28.4.6: AES ciphertext stealing and data padding](#). The second-last and the last block management in these cases is more complex than in the sequence described in this section.

### Data append through polling

This method uses flag polling to control the data append.

For all other cases, the data is appended through the following sequence:

1. Enable the AES peripheral by setting the EN bit of the AES\_CR register.
2. Repeat the following sub-sequence until the payload is entirely processed:
  - a) Write four input data words into the AES\_DINR register.
  - b) Wait until the status flag CCF is set in the AES\_SR, then read the four data words from the AES\_DOUTR register.
  - c) Clear the CCF flag, by setting the CCFC bit of the AES\_CR register.
  - d) If the data block just processed is the second-last block of the message and the significant data in the last block to process is inferior to 128 bits, pad the remainder of the last block with zeros
3. Discard the data that is not part of the payload, then disable the AES peripheral by clearing the EN bit of the AES\_CR register.

*Note: Up to three wait cycles are automatically inserted between two consecutive writes to the AES\_DINR register, to allow sending the key to the AES processor.*

### Data append using interrupt

The method uses interrupt from the AES peripheral to control the data append, through the following sequence:

1. Enable interrupts from AES by setting the CCFIE bit of the AES\_CR register.
2. Enable the AES peripheral by setting the EN bit of the AES\_CR register.
3. Write first four input data words into the AES\_DINR register.
4. Handle the data in the AES interrupt service routine, upon interrupt:
  - a) Read four output data words from the AES\_DOUTR register.
  - b) Clear the CCF flag and thus the pending interrupt, by setting the CCFC bit of the AES\_CR register
  - c) If the data block just processed is the second-last block of an message and the significant data in the last block to process is inferior to 128 bits, pad the remainder of the last block with zeros. Then proceed with point 4e).
  - d) If the data block just processed is the last block of the message, discard the data that is not part of the payload, then disable the AES peripheral by clearing the EN bit of the AES\_CR register and quit the interrupt service routine.
  - e) Write next four input data words into the AES\_DINR register and quit the interrupt service routine.

*Note: AES is tolerant of delays between consecutive read or write operations, which allows, for example, an interrupt from another peripheral to be served between two AES computations.*

### Data append using DMA

With this method, all the transfers and processing are managed by DMA and AES. To use the method, proceed as follows:

1. Prepare the last four-word data block (if the data to process does not fill it completely), by padding the remainder of the block with zeros.
2. Configure the DMA controller so as to transfer the data to process from the memory to the AES peripheral input and the processed data from the AES peripheral output to the memory, as described in [Section 28.4.16: AES DMA interface](#). Configure the DMA controller so as to generate an interrupt on transfer completion.
3. Enable the AES peripheral by setting the EN bit of the AES\_CR register.
4. Enable DMA requests by setting the DMAINEN and DMAOUTEN bits of the AES\_CR register.
5. Upon DMA interrupt indicating the transfer completion, get the AES-processed data from the memory.

*Note:* The CCF flag has no use with this method, because the reading of the AES\_DOUTR register is managed by DMA automatically, without any software action, at the end of the computation phase.

### 28.4.5 AES decryption key preparation

For an ECB or CBC decryption, a key for the first round of decryption must be derived from the key of the last round of encryption. This is why a complete key schedule of encryption is required before performing the decryption. This key preparation is **not required** for AES decryption in modes other than ECB or CBC.

Recommended method is to select the Mode 2 by setting to 01 the MODE[1:0] bitfield of the AES\_CR (key process only), then proceed with the decryption by setting MODE[1:0] to 10 (Mode 3, decryption only). Mode 2 usage is described below:

1. Disable the AES peripheral by clearing the EN bit of the AES\_CR register.
2. Select Mode 2 by setting to 01 the MODE[1:0] bitfield of the AES\_CR. The CHMOD[2:0] bitfield is not significant in this case because this key derivation mode is independent of the chaining algorithm selected.
3. Set key length to 128 or 256 bits, via KEYSIZE bit of AES\_CR register.
4. Write the AES\_KEYRx registers (128 or 256 bits) with encryption key, as shown in [Figure 199](#). Writes to the AES\_IVRx registers have no effect.
5. Enable the AES peripheral, by setting the EN bit of the AES\_CR register.
6. Wait until the CCF flag is set in the AES\_SR register.
7. Derived key is available in AES core, ready to use for decryption. Application can also read the AES\_KEYRx register to obtain the derived key if needed, as shown in [Figure 199](#) (the processed key is loaded automatically into the AES\_KEYRx registers).

*Note:* The AES is disabled by hardware when the derivation key is available.  
To restart a derivation key computation, repeat steps 4, 5, 6 and 7.

Figure 199. Encryption key derivation for ECB/CBC decryption (Mode 2)

If the software stores the initial key prepared for decryption, it is enough to do the key schedule operation only once for all the data to be decrypted with a given cipher key.

**Note:** The operation of the key preparation lasts 80 or 109 clock cycles, depending on the key size (128- or 256-bit).

**Note:** Alternative key preparation is to select Mode 4 by setting to 11 the MODE[1:0] bitfield of the AES\_CR register. In this case Mode 3 cannot be used.

#### 28.4.6 AES ciphertext stealing and data padding

When using AES in ECB or CBC modes to manage messages the size of which is not a multiple of the block size (128 bits), ciphertext stealing techniques are used, such as those described in NIST *Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation: Three Variants of Ciphertext Stealing for CBC Mode*. Since the AES peripheral on the device does not support such techniques, **the last two blocks** of input data must be handled in a special way by the application.

**Note:** Ciphertext stealing techniques are not documented in this reference manual.

Similarly, when AES is used in other modes than ECB or CBC, an incomplete input data block (that is, block with input data shorter than 128 bits) must be padded with zeros prior to encryption (that is, extra bits must be appended to the trailing end of the data string). After decryption, the extra bits must be discarded. As AES does not implement automatic data padding operation to **the last block**, the application must follow the recommendation given in [Section 28.4.4: AES procedure to perform a cipher operation on page 828](#) to manage messages the size of which is not a multiple of 128 bits.

**Note:** Padding data are swapped in a similar way as normal data, according to the DATATYPE[1:0] field of the AES\_CR register (see [Section 28.4.13: AES data registers and data swapping on page 854](#) for details).

A workaround is required in order to properly compute authentication tags for **GCM encryption**, when the input data in the last block is **inferior to 128 bits**. During GCM encryption payload phase and before inserting a last plaintext block smaller than 128 bits, then application must apply the following steps:

1. Disable the AES peripheral by clearing the EN bit of the AES\_CR register
2. Change the mode to CTR by writing 010 to the CHMOD[2:0] bitfield of the AES\_CR register.
3. Pad the last block (smaller than 128 bits) with zeros to have a complete block of 128 bits, then write it into AES\_DINR register.
4. Upon encryption completion, read the 128-bit ciphertext from the AES\_DOUTR register and store it as intermediate data.
5. Change again the mode to GCM by writing 011 to the CHMOD[2:0] bitfield of the AES\_CR register.
6. Select Final phase by writing 11 to the GCMPH[1:0] bitfield of the AES\_CR register.
7. In the intermediate data, set to zero the bits corresponding to the padded bits of the last block of payload, then insert the resulting data into AES\_DINR register.
8. Wait for operation completion, and read data on AES\_DOUTR. This data is to be discarded.
9. Apply the normal Final phase as described in [Section 28.4.10: AES Galois/counter mode \(GCM\) on page 842](#)

### 28.4.7 AES task suspend and resume

A message can be suspended if another message with a higher priority must be processed. When this highest priority message is sent, the suspended message can resume in both encryption or decryption mode.

Suspend/resume operations do not break the chaining operation and the message processing can resume as soon as AES is enabled again to receive the next data block.

[Figure 200](#) gives an example of suspend/resume operation: Message 1 is suspended in order to send a shorter and higher-priority Message 2.

**Figure 200. Example of suspend mode management**

A detailed description of suspend/resume operations is in the sections dedicated to each AES mode.

## 28.4.8 AES basic chaining modes (ECB, CBC)

### Overview

This section gives a brief explanation of the four basic operation modes provided by the AES computing core: ECB encryption, ECB decryption, CBC encryption and CBC decryption. For detailed information, refer to the FIPS publication 197 from November 26, 2001.

Figure 201 illustrates the electronic codebook (ECB) encryption.

In ECB encrypt mode, the 128-bit plaintext input data block Px in the AES\_DINR register first goes through bit/byte/half-word swapping. The swap result Ix is processed with the AES core set in encrypt mode, using a 128- or 256-bit key. The encryption result Ox goes through bit/byte/half-word swapping, then is stored in the AES\_DOUTR register as 128-bit ciphertext output data block Cx. The ECB encryption continues in this way until the last complete plaintext block is encrypted.

Figure 202 illustrates the electronic codebook (ECB) decryption.

To perform an AES decryption in the ECB mode, the secret key has to be prepared by collecting the last-round encryption key (which requires to first execute the complete key schedule for encryption), and using it as the first-round key for the decryption of the ciphertext. This preparation is supported by the AES core.

In ECB decrypt mode, the 128-bit ciphertext input data block C1 in the AES\_DINR register first goes through bit/byte/half-word swapping. The keying sequence is reversed compared to that of the ECB encryption. The swap result I1 is processed with the AES core set in decrypt mode, using the formerly prepared decryption key. The decryption result goes through bit/byte/half-word swapping, then is stored in the AES\_DOUTR register as 128-bit plaintext output data block P1. The ECB decryption continues in this way until the last complete ciphertext block is decrypted.

Figure 203 illustrates the cipher block chaining (CBC) encryption mode.

In CBC encrypt mode, the first plaintext input block, after bit/byte/half-word swapping (P1'), is XOR-ed with a 128-bit IVI bitfield (initialization vector and counter), producing the I1 input data for encrypt with the AES core, using a 128- or 256-bit key. The resulting 128-bit output block O1, after swapping operation, is used as ciphertext C1. The O1 data is then XOR-ed with the second-block plaintext data P2' to produce the I2 input data for the AES core to produce the second block of ciphertext data. The chaining of data blocks continues in this way until the last plaintext block in the message is encrypted.

If the message size is not a multiple of 128 bits, the final partial data block is encrypted in the way explained in [Section 28.4.6: AES ciphertext stealing and data padding](#).

Figure 204 illustrates the cipher block chaining (CBC) decryption mode.

In CBC decrypt mode, like in ECB decrypt mode, the secret key must be prepared to perform an AES decryption.

After the key preparation process, the decryption goes as follows: the first 128-bit ciphertext block (after the swap operation) is used directly as the AES core input block I1 for decrypt operation, using the 128-bit or 256-bit key. Its output O1 is XOR-ed with the 128-bit IVI field (that must be identical to that used during encryption) to produce the first plaintext block P1.

The second ciphertext block is processed in the same way as the first block, except that the I1 data from the first block is used in place of the initialization vector.

The decryption continues in this way until the last complete ciphertext block is decrypted.

If the message size is not a multiple of 128 bits, the final partial data block is decrypted in the way explained in [Section 28.4.6: AES ciphertext stealing and data padding](#).

For more information on data swapping, refer to [Section 28.4.13: AES data registers and data swapping](#).

### ECB/CBC encryption sequence

The sequence of events to perform an ECB/CBC encryption (more detail in [Section 28.4.4](#)):

1. Disable the AES peripheral by clearing the EN bit of the AES\_CR register.
2. Select the Mode 1 by to 00 the MODE[1:0] bitfield of the AES\_CR register and select ECB or CBC chaining mode by setting the CHMOD[2:0] bitfield of the AES\_CR register to 000 or 001, respectively. Data type can also be defined, using DATATYPE[1:0] bitfield.
3. Select 128- or 256-bit key length through the KEYSIZE bit of the AES\_CR register.
4. Write the AES\_KEYRx registers (128 or 256 bits) with encryption key. Fill the AES\_IVRx registers with the initialization vector data if CBC mode has been selected.
5. Enable the AES peripheral by setting the EN bit of the AES\_CR register.
6. Write the AES\_DINR register four times to input the plaintext (MSB first), as shown in [Figure 205](#).
7. Wait until the CCF flag is set in the AES\_SR register.
8. Read the AES\_DOUTR register four times to get the ciphertext (MSB first) as shown in [Figure 205](#). Then clear the CCF flag by setting the CCFC bit of the AES\_CR register.
9. Repeat steps 6,7,8 to process all the blocks with the same encryption key.

**Figure 205. ECB/CBC encryption (Mode 1)**

## ECB/CBC decryption sequence

The sequence of events to perform an AES ECB/CBC decryption is as follows (more detail in [Section 28.4.4](#)):

1. Follow the steps described in [Section 28.4.5: AES decryption key preparation on page 832](#), in order to prepare the decryption key in AES core.
2. Disable the AES peripheral by clearing the EN bit of the AES\_CR register.
3. Select the Mode 3 by setting to 10 the MODE[1:0] bitfield of the AES\_CR register and select ECB or CBC chaining mode by setting the CHMOD[2:0] bitfield of the AES\_CR register to 000 or 001, respectively. Data type can also be defined, using DATATYPE[1:0] bitfield.
4. Select key length of 128 or 256 bits via KEYSIZE bitfield of the AES\_CR register.
5. Write the AES\_IVRx registers with the initialization vector (required in CBC mode only).
6. Enable AES by setting the EN bit of the AES\_CR register.
7. Write the AES\_DINR register four times to input the cipher text (MSB first), as shown in [Figure 206](#).
8. Wait until the CCF flag is set in the AES\_SR register.
9. Read the AES\_DOUTR register four times to get the plain text (MSB first), as shown in [Figure 206](#). Then clear the CCF flag by setting the CCFC bit of the AES\_CR register.
10. Repeat steps 7,8,9 to process all the blocks encrypted with the same key.

**Figure 206. ECB/CBC decryption (Mode 3)**

## Suspend/resume operations in ECB/CBC modes

To suspend the processing of a message, proceed as follows:

1. If DMA is used, stop the AES DMA transfers to the IN FIFO by clearing the DMAINEN bit of the AES\_CR register.
2. If DMA is not used, read four times the AES\_DOUTR register to save the last processed block. If DMA is used, wait until the CCF flag is set in the AES\_SR register

then stop the DMA transfers from the OUT FIFO by clearing the DMAOUTEN bit of the AES\_CR register.

3. If DMA is not used, poll the CCF flag of the AES\_SR register until it becomes 1 (computation completed).
4. Clear the CCF flag by setting the CCFC bit of the AES\_CR register.
5. Save initialization vector registers (only required in CBC mode as AES\_IVRx registers are altered during the data processing).
6. Disable the AES peripheral by clearing the bit EN of the AES\_CR register.
7. Save the current AES configuration in the memory (except AES initialization vector values).
8. If DMA is used, save the DMA controller status (pointers for IN and OUT data transfers, number of remaining bytes, and so on).

*Note:* In point 7, the derived key information stored in AES\_KEYRx registers can optionally be saved in memory if the interrupted process is a decryption. Otherwise those registers do not need to be saved as the original key value is known by the application

**To resume the processing of a message**, proceed as follows:

1. If DMA is used, configure the DMA controller so as to complete the rest of the FIFO IN and FIFO OUT transfers.
2. Ensure that AES is disabled (the EN bit of the AES\_CR must be 0).
3. Restore the AES\_CR and AES\_KEYRx register setting, using the values of the saved configuration. In case of decryption, derived key information can be written in AES\_KEYRx register instead of the original key value.
4. Prepare the decryption key as described in [Section 28.4.5: AES decryption key preparation](#) (only required for ECB or CBC decryption). This step is not necessary if derived key information has been loaded in AES\_KEYRx registers.
5. Restore AES\_IVRx registers using the saved configuration (only required in CBC mode).
6. Enable the AES peripheral by setting the EN bit of the AES\_CR register.
7. If DMA is used, enable AES DMA transfers by setting the DMAINEN and DMAOUTEN bits of the AES\_CR register.

### Alternative single ECB/CBC decryption using Mode 4

The sequence of events to perform a single round of ECB/CBC decryption using Mode 4 is:

1. Disable the AES peripheral by clearing the EN bit of the AES\_CR register.
2. Select the Mode 4 by setting to 11 the MODE[1:0] bitfield of the AES\_CR register and select ECB or CBC chaining mode by setting the CHMOD[2:0] bitfield of the AES\_CR register to 000 or 001, respectively.
3. Select key length of 128 or 256 bits via KEYSIZE bitfield of the AES\_CR register.
4. Write the AES\_KEYRx registers with the encryption key. Write the AES\_IVRx registers if the CBC mode is selected.
5. Enable the AES peripheral by setting the EN bit of the AES\_CR register.
6. Write the AES\_DINR register four times to input the cipher text (MSB first).
7. Wait until the CCF flag is set in the AES\_SR register.
8. Read the AES\_DOUTR register four times to get the plain text (MSB first). Then clear the CCF flag by setting the CCFC bit of the AES\_CR register.

**Note:** When mode 4 is selected mode 3 cannot be used.

In mode 4, the `AES_KEYRx` registers contain the encryption key during all phases of the processing. No derivation key is stored in these registers. It is stored internally in AES.

### 28.4.9 AES counter (CTR) mode

#### Overview

The counter mode (CTR) uses AES as a key-stream generator. The generated keys are then XOR-ed with the plaintext to obtain the ciphertext.

CTR chaining is defined in NIST *Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation*. A typical message construction in CTR mode is given in [Figure 207](#).

**Figure 207. Message construction in CTR mode**

The structure of this message is:

- A 16-byte initial counter block (ICB), composed of two distinct fields:
  - **Initialization vector (IV)**: a 96-bit value that must be unique for each encryption cycle with a given key.
  - **Counter**: a 32-bit big-endian integer that is incremented each time a block processing is completed. The initial value of the counter should be set to 1.
- The plaintext P is encrypted as ciphertext C, with a known length. This length can be non-multiple of 16 bytes, in which case a plaintext padding is required.

#### CTR encryption and decryption

[Figure 208](#) and [Figure 209](#) describe the CTR encryption and decryption process, respectively, as implemented in the AES peripheral. The CTR mode is selected by writing 010 to the `CHMOD[2:0]` bitfield of `AES_CR` register.

Figure 208. CTR encryption

Figure 209. CTR decryption

In CTR mode, the cryptographic core output (also called keystream)  $Ox$  is XOR-ed with relevant input block ( $Px'$  for encryption,  $Cx'$  for decryption), to produce the correct output block ( $Cx'$  for encryption,  $Px'$  for decryption). Initialization vectors in AES must be initialized as shown in [Table 180](#).

Table 180. CTR mode initialization vector definition

| AES_IVR3[31:0] | AES_IVR2[31:0] | AES_IVR1[31:0] | AES_IVR0[31:0]          |
|----------------|----------------|----------------|-------------------------|
| Nonce[31:0]    | Nonce[63:32]   | Nonce[95:64]   | 32-bit counter = 0x0001 |

Unlike in CBC mode that uses the AES\_IVRx registers only once when processing the first data block, in CTR mode AES\_IVRx registers are used for processing each data block, and the AES peripheral increments the counter bits of the initialization vector (leaving the nonce bits unchanged).

CTR decryption does not differ from CTR encryption, since the core always encrypts the current counter block to produce the key stream that is then XOR-ed with the plaintext (CTR

encryption) or ciphertext (CTR decryption) input. In CTR mode, the MODE[1:0] bitfield settings 11, 10 or 00 default all to encryption mode, and the setting 01 (key derivation) is forbidden.

The sequence of events to perform an encryption or a decryption in CTR chaining mode:

1. Ensure that AES is disabled (the EN bit of the AES\_CR must be 0).
2. Select CTR chaining mode by setting to 010 the CHMOD[2:0] bitfield of the AES\_CR register. Set MODE[1:0] bitfield to any value other than 01.
3. Initialize the AES\_KEYRx registers, and load the AES\_IVRx registers as described in [Table 180](#).
4. Set the EN bit of the AES\_CR register, to start encrypting the current counter (EN is automatically reset when the calculation finishes).
5. If it is the last block, pad the data with zeros to have a complete block, if needed.
6. Append data in AES, and read the result. The three possible scenarios are described in [Section 28.4.4: AES procedure to perform a cipher operation](#).
7. Repeat the previous step till the second-last block is processed. For the last block, apply the two previous steps and discard the bits that are not part of the payload (if the size of the significant data in the last input block is less than 16 bytes).

### Suspend/resume operations in CTR mode

Like for the CBC mode, it is possible to interrupt a message to send a higher priority message, and resume the message that was interrupted. Detailed CBC suspend/resume sequence is described in [Section 28.4.8: AES basic chaining modes \(ECB, CBC\)](#).

*Note:* Like for CBC mode, the AES\_IVRx registers must be reloaded during the resume operation.

## 28.4.10 AES Galois/counter mode (GCM)

### Overview

The AES Galois/counter mode (GCM) allows encrypting and authenticating a plaintext message into the corresponding ciphertext and tag (also known as message authentication code). To ensure confidentiality, GCM algorithm is based on AES counter mode. It uses a multiplier over a fixed finite field to generate the tag.

GCM chaining is defined in NIST *Special Publication 800-38D, Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC*. A typical message construction in GCM mode is given in [Figure 210](#).

Figure 210. Message construction in GCM

The message has the following structure:

- **16-byte initial counter block (ICB)**, composed of two distinct fields:
  - **Initialization vector (IV)**: a 96-bit value that must be unique for each encryption cycle with a given key. Note that the GCM standard supports IVs with less than 96 bits, but in this case strict rules apply.
  - **Counter**: a 32-bit big-endian integer that is incremented each time a block processing is completed. According to NIST specification, the counter value is 0x2 when processing the first block of payload.
- **Authenticated header AAD** (also known as additional authentication data) has a known length Len(A) that may be a non-multiple of 16 bytes, and must not exceed  $2^{64} - 1$  bits. This part of the message is only authenticated, not encrypted.
- **Plaintext message P** is both authenticated and encrypted as ciphertext C, with a known length Len(P) that may be non-multiple of 16 bytes, and cannot exceed  $2^{32} - 2$  128-bit blocks.
- **Last block** contains the AAD header length (bits [32:63]) and the payload length (bits [96:127]) information, as shown in [Table 181](#).

The GCM standard specifies that ciphertext C has the same bit length as the plaintext P.

When a part of the message (AAD or P) has a length that is a non-multiple of 16-bytes a special padding scheme is required.

Table 181. GCM last block definition

| Endianness | Bit[0] ----- Bit[31] | Bit[32]----- Bit[63] | Bit[64] ----- Bit[95] | Bit[96] ----- Bit[127] |
|------------|----------------------|----------------------|-----------------------|------------------------|
| Input data | 0x0                  | AAD length[31:0]     | 0x0                   | Payload length[31:0]   |

## GCM processing

Figure 211 describes the GCM implementation in the AES peripheral. The GCM is selected by writing 011 to the CHMOD[2:0] bitfield of the AES\_CR register.

Figure 211. GCM authenticated encryption

The mechanism for the confidentiality of the plaintext in GCM mode is similar to that in the Counter mode, with a particular increment function (denoted 32-bit increment) that generates the sequence of input counter blocks.

AES\_IVRx registers keeping the **counter block** of data are used for processing each data block. The AES peripheral automatically increments the Counter[31:0] bitfield. The first counter block (CB1) is derived from the initial counter block ICB by the application software (see Table 182).

Table 182. GCM mode IVI bitfield initialization

| Register   | AES_IVR3[31:0] | AES_IVR2[31:0] | AES_IVR1[31:0] | AES_IVR0[31:0]      |
|------------|----------------|----------------|----------------|---------------------|
| Input data | ICB[31:0]      | ICB[63:32]     | ICB[95:64]     | Counter[31:0] = 0x2 |

Note: In GCM mode, the settings 01 and 11 of the MODE[1:0] bitfield are forbidden.

The authentication mechanism in GCM mode is based on a hash function called **GF2mul** that performs multiplication by a fixed parameter, called hash subkey (H), within a binary Galois field.

A GCM message is processed through the following phases, further described in next subsections:

- **Init phase:** AES prepares the GCM hash subkey (H).
- **Header phase:** AES processes the additional authenticated data (AAD), with hash computation only.
- **Payload phase:** AES processes the plaintext (P) with hash computation, counter block encryption and data XOR-ing. It operates in a similar way for ciphertext (C).
- **Final phase:** AES generates the authenticated tag (T) using the last block of the message.

### GCM init phase

During this first step, the GCM hash subkey (H) is calculated and saved internally, to be used for processing all the blocks. The recommended sequence is:

1. Ensure that AES is disabled (the EN bit of the AES\_CR must be 0).
2. Select GCM chaining mode, by setting to 011 the CHMOD[2:0] bitfield of the AES\_CR register, and set to 00 (no data swapping) the DATATYPE[1:0] bitfield.
3. Indicate the Init phase, by setting to 00 the GCMPH[1:0] bitfield of the AES\_CR register.
4. Set the MODE[1:0] bitfield of the AES\_CR register to 00 or 10.
5. Initialize the AES\_KEYRx registers with a key, and initialize AES\_IVRx registers with the information as defined in [Table 182](#).
6. Start the calculation of the hash key, by setting to 1 the EN bit of the AES\_CR register (EN is automatically reset when the calculation finishes).
7. Wait until the end of computation, indicated by the CCF flag of the AES\_SR transiting to 1. Alternatively, use the corresponding interrupt.
8. Clear the CCF flag of the AES\_SR register, by setting to 1 the CCFC bit of the AES\_CR register, and optionally set the data type (1-, 8- or 16-bit) using the DATATYPE[1:0] bitfield.

### GCM header phase

This phase coming after the GCM Init phase must be completed before the payload phase. The sequence to execute, identical for encryption and decryption, is:

1. Indicate the header phase, by setting to 01 the GCMPH[1:0] bitfield of the AES\_CR register. Do not modify the MODE[1:0] bitfield as set in the Init phase.
2. Enable the AES peripheral by setting the EN bit of the AES\_CR register.
3. If it is the last block and the AAD size in the block is inferior to 128 bits, pad the remainder of the block with zeros. Then append the data block into AES in one of ways described in [Section 28.4.4: AES procedure to perform a cipher operation on page 828](#).
4. Repeat the step 3 until the last additional authenticated data block is processed.

*Note:* The header phase can be skipped if there is no AAD, that is,  $Len(A) = 0$ .

### GCM payload phase

This phase, identical for encryption and decryption, is executed after the GCM header phase. During this phase, the encrypted/decrypted payload is stored in the AES\_DOUTR register. The sequence to execute is:

1. If the header phase was skipped, enable the AES peripheral by setting the EN bit of the AES\_CR register.
2. Indicate the payload phase, by setting to 10 the GCMPPH[1:0] bitfield of the AES\_CR register. Do not modify the MODE[1:0] bitfield as set in the Init phase.
3. If it is the last block and the plaintext (encryption) or ciphertext (decryption) size in the block is inferior to 128 bits, pad the remainder of the block with zeros.
4. Append the data block into AES in one of ways described in [Section 28.4.4: AES procedure to perform a cipher operation on page 828](#), and read the result.
5. Repeat the previous step till the second-last plaintext block is encrypted or till the last block of ciphertext is decrypted. For the last block of plaintext (encryption only), execute the two previous steps. For the last block, discard the bits that are not part of the payload when the last block size is less than 16 bytes.

**Note:** *The payload phase can be skipped if there is no payload data, that is,  $Len(C) = 0$  (see GMAC mode).*

### GCM final phase

In this last phase, the AES peripheral generates the GCM authentication tag and stores it in the AES\_DOUTR register. The sequence to execute is:

1. Indicate the final phase, by setting to 11 the GCMPPH[1:0] bitfield of the AES\_CR register. Select encrypt mode by setting to 00 the MODE[1:0] bitfield of the AES\_CR register.
2. Compose the data of the block, by concatenating the AAD bit length and the payload bit length, as shown in [Table 181](#). Write the block into the AES\_DINR register.
3. Wait until the end of computation, indicated by the CCF flag of the AES\_SR transiting to 1.
4. Get the GCM authentication tag, by reading the AES\_DOUTR register four times.
5. Clear the CCF flag in the AES\_SR register, by setting to 1 the CCFC bit of the AES\_CR register.
6. Disable the AES peripheral, by clearing the bit EN of the AES\_CR register. If it is an authenticated decryption, compare the generated tag with the expected tag passed with the message.

**Note:** *In the final phase, data must be swapped according to the data type set in the DATATYPE[1:0] bitfield of the AES\_CR register.*

*When transiting from the header or the payload phase to the final phase, the AES peripheral must not be disabled, otherwise the result is wrong.*

### Suspend/resume operations in GCM mode

**To suspend the processing of a message**, proceed as follows:

1. If DMA is used, stop the AES DMA transfers to the IN FIFO by clearing the DMAINEN bit of the AES\_CR register. If DMA is not used, make sure that the current computation is completed, which is indicated by the CCF flag of the AES\_SR register set to 1.
2. In the payload phase, if DMA is not used, read four times the AES\_DOUTR register to save the last-processed block. If DMA is used, wait until the CCF flag is set in the AES\_SR register then stop the DMA transfers from the OUT FIFO by clearing the DMAOUTEN bit of the AES\_CR register.
3. Clear the CCF flag of the AES\_SR register, by setting to 1 the CCFC bit of the AES\_CR register. In the payload phase (encryption mode only), verify that the BUSY flag of the AES\_SR register is cleared, to ensure that GF2mul hash function is completed.
4. Save the AES\_SUSPxR registers in the memory, where x is from 0 to 7.
5. In the payload phase, save the AES\_IVRx registers as, during the data processing, they changed from their initial values. In the header phase, this step is not required.
6. Disable the AES peripheral, by clearing the EN bit of the AES\_CR register.
7. Save the current AES configuration in the memory, excluding the initialization vector registers AES\_IVRx. Key registers do not need to be saved as the original key value is known by the application.
8. If DMA is used, save the DMA controller status (pointers for IN data transfers, number of remaining bytes, and so on). In the payload phase, pointers for OUT data transfers must also be saved.

**To resume the processing of a message**, proceed as follows:

1. If DMA is used, configure the DMA controller in order to complete the rest of the FIFO IN transfers. In the payload phase, the rest of the FIFO OUT transfers must also be configured in the DMA controller.
2. Ensure that the AES peripheral is disabled (the EN bit of the AES\_CR register must be 0).
3. Write the suspend register values, previously saved in the memory, back into their corresponding AES\_SUSPxR registers, where x is from 0 to 7.
4. In the payload phase, write the initialization vector register values, previously saved in the memory, back into their corresponding AES\_IVRx registers. In the header phase, write initial setting values back into the AES\_IVRx registers.
5. Restore the initial setting values in the AES\_CR and AES\_KEYRx registers.
6. Enable the AES peripheral by setting the EN bit of the AES\_CR register.
7. If DMA is used, enable AES DMA requests by setting the DMAINEN bit (and DMAOUTEN bit if in payload phase) of the AES\_CR register.

## 28.4.11 AES Galois message authentication code (GMAC)

### Overview

The Galois message authentication code (GMAC) allows the authentication of a plaintext, generating the corresponding tag information (also known as message authentication code). It is based on GCM algorithm, as defined in NIST *Special Publication 800-38D, Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC*.

A typical message construction for GMAC is given in [Figure 212](#).

**Figure 212. Message construction in GMAC mode**

### AES GMAC processing

[Figure 213](#) describes the GMAC mode implementation in the AES peripheral. This mode is selected by writing 011 to the CHMOD[2:0] bitfield of the AES\_CR register.

**Figure 213. GMAC authentication mode**

The GMAC algorithm corresponds to the GCM algorithm applied on a message only containing a header. As a consequence, all steps and settings are the same as with the GCM, except that the payload phase is omitted.

### Suspend/resume operations in GMAC

In GMAC mode, the sequence described for the GCM applies except that only the header phase can be interrupted.

## 28.4.12 AES counter with CBC-MAC (CCM)

### Overview

The AES **counter with cipher block chaining-message authentication code (CCM)** algorithm allows encryption and authentication of plaintext, generating the corresponding ciphertext and tag (also known as message authentication code). To ensure confidentiality, the CCM algorithm is based on AES in counter mode. It uses cipher block chaining technique to generate the message authentication code. This is commonly called CBC-MAC.

**Note:** *NIST does not approve this CBC-MAC as an authentication mode outside the context of the CCM specification.*

CCM chaining is specified in NIST *Special Publication 800-38C, Recommendation for Block Cipher Modes of Operation - The CCM Mode for Authentication and Confidentiality*. A typical message construction for CCM is given in [Figure 214](#).

**Figure 214. Message construction in CCM mode**

The structure of the message is:

- 16-byte first authentication block (B0)**, composed of three distinct fields:
  - Q:** a bit string representation of the octet length of P ( $\text{Len}(P)$ )
  - Nonce (N):** a single-use value (that is, a new nonce should be assigned to each new communication) of  $\text{Len}(N)$  size. The sum  $\text{Len}(N) + \text{Len}(P)$  must be equal to 15 bytes.
  - Flags:** most significant octet containing four flags for control information, as specified by the standard. It contains two 3-bit strings to encode the values  $t$  (MAC length expressed in bytes) and  $Q$  (plaintext length such that  $\text{Len}(P) < 2^{8Q}$  bytes). The counter blocks range associated to  $Q$  is equal to  $2^{8Q-4}$ , that is, if the maximum value of  $Q$  is 8, the counter blocks used in cipher shall be on 60 bits.
- 16-byte blocks (B)** associated to the Associated Data (A).  
 This part of the message is only authenticated, not encrypted. This section has a known length  $\text{Len}(A)$  that can be a non-multiple of 16 bytes (see [Figure 214](#)). The

standard also states that, on MSB bits of the first message block (B1), the associated data length expressed in bytes (a) must be encoded as follows:

- If  $0 < a < 2^{16} - 2^8$ , then it is encoded as  $[a]_{16}$ , that is, on two bytes.
- If  $2^{16} - 2^8 < a < 2^{32}$ , then it is encoded as  $0xff \parallel 0xfe \parallel [a]_{32}$ , that is, on six bytes.
- If  $2^{32} < a < 2^{64}$ , then it is encoded as  $0xff \parallel 0xff \parallel [a]_{64}$ , that is, on ten bytes.
- **16-byte blocks (B)** associated to the plaintext message P, which is both authenticated and encrypted as ciphertext C, with a known length  $\text{Len}(P)$ . This length can be a non-multiple of 16 bytes (see [Figure 214](#)).
- **Encrypted MAC (T)** of length  $\text{Len}(T)$  appended to the ciphertext C of overall length  $\text{Len}(C)$ .

When a part of the message (A or P) has a length that is a non-multiple of 16-bytes, a special padding scheme is required.

*Note: CCM chaining mode can also be used with associated data only (that is, no payload).*

As an example, the C.1 section in NIST Special Publication 800-38C gives the following values (hexadecimal numbers):

```
N: 10111213 141516 (Len(N)= 56 bits or 7 bytes)
A: 00010203 04050607 (Len(A)= 64 bits or 8 bytes)
P: 20212223 (Len(P)= 32 bits or 4 bytes)
T: 6084341B (Len(T)= 32 bits or t = 4)
B0: 4F101112 13141516 00000000 00000004
B1: 00080001 02030405 06070000 00000000
B2: 20212223 00000000 00000000 00000000
CTR0: 0710111213 141516 00000000 00000000
CTR1: 0710111213 141516 00000000 00000001
```

Generation of formatted input data blocks Bx (especially B0 and B1) must be managed by the application.

### CCM processing

Figure 215 describes the CCM implementation within the AES peripheral (decryption example).

Figure 215. CCM mode authenticated decryption

The data input to the generation-encryption process are a valid nonce, a valid payload string, and a valid associated data string, all properly formatted. The CBC chaining mechanism is applied to the formatted plaintext data to generate a MAC, with a known length. Counter mode encryption that requires a sufficiently long sequence of counter blocks as input, is applied to the payload string and separately to the MAC. The resulting ciphertext C is the output of the generation-encryption process on plaintext P.

AES\_IVRx registers are used for processing each data block, AES automatically incrementing the CTR counter with a bit length defined by the first block B0. Table 183 shows how the application must load the B0 data.

Table 183. Initialization of AES\_IVRx registers in CCM mode

| Register   | AES_IVR3[31:0] | AES_IVR2[31:0] | AES_IVR1[31:0] | AES_IVR0[31:0] |
|------------|----------------|----------------|----------------|----------------|
| Input data | B0[31:0]       | B0[63:32]      | B0[95:64]      | B0[127:96]     |

A CCM message is processed through two distinct processes - first, **payload encryption or decryption**, in which the AES peripheral is configured in CTR mode, then **associated data and payload authentication**, in which the AES peripheral first executes the CCM header phase, then the CCM final phase.

#### Payload encryption/decryption

This step is performed independently of the tag computation. It uses standard CTR chaining mode. Refer to [Section 28.4.9: AES counter \(CTR\) mode](#) for details. The construction of the CTR1 initialization vector (see [Figure 215](#)) to load into AES\_IVRx registers is defined in NIST Special Publication 800-38C.

*Note:* This phase can be skipped if there is no payload data, that is, when  $Len(P) = 0$  or  $Len(C) = Len(T)$ .

*Remove  $LSB_{Len(T)}(C)$  encrypted tag information when decrypting ciphertext C.*

#### Associated data and payload authentication

In order to compute the CCM authentication tag associated with the plaintext message, it is recommended to execute the following header phase sequence:

1. Ensure that the AES peripheral is disabled (the EN bit of the AES\_CR must be 0).
2. Select CCM chaining mode, by setting to 100 the CHMOD[2:0] bitfield of the AES\_CR register, and optionally, set the DATATYPE[1:0] bitfield.
3. Indicate the header phase, by setting to 01 the GCMPLH[1:0] bitfield of the AES\_CR register. Select encrypt mode by setting to 00 the MODE[1:0] bitfield of the AES\_CR register.
4. Initialize the AES\_KEYRx registers with a key, and initialize AES\_IVRx registers with zero values.
5. Enable the AES peripheral by setting the EN bit of the AES\_CR register.
6. Write the AES\_DINR register with B0, as shown in [Table 183](#). B0 data must be swapped according to the DATATYPE[1:0] bitfield of the AES\_CR register.
7. Wait until the end-of-computation flag CCF of the AES\_SR register is set to 1.
8. Clear the CCF flag of the AES\_SR register by setting the CCFC bit of the AES\_CR register.
9. Process data block. If it is the last block of associated data or plaintext and data size in the block is inferior to 128 bits, pad the remainder of the block with zeros. Then append the data block into AES in one of ways described in [Section 28.4.4: AES procedure to perform a cipher operation on page 828](#).
10. Repeat the previous step to process all data blocks, starting from the first block of associated data and ending with the last block of plaintext payload data.

In final phase, the AES peripheral generates the CCM authentication tag and stores it in the AES\_DOUTR register:

11. Indicate the final phase, by setting to 11 the GCMPPH[1:0] bitfield of the AES\_CR register. Keep as-is the encryption mode in the MODE[1:0] bitfield.
12. Write four times the last data input into the AES\_DIN register. This input must be the 128-bit value CTR0, formatted from the original B0 packet (that is, 5 flag bits set to 0, and Q length bits set to 0).
13. Wait until the end-of-computation flag CCF of the AES\_SR register is set.
14. Read four times the AES\_DOUTR register: the output corresponds to the encrypted CCM authentication tag.
15. Clear the CCF flag of the AES\_SR register by setting the CCFC bit of the AES\_CR register.
16. Disable the AES peripheral, by clearing the EN bit of the AES\_CR register.
17. For authenticated decryption, compare the generated encrypted tag with the encrypted tag padded in the ciphertext.

**Note:** *In this final phase, data must be swapped according to the DATATYPE[1:0] bitfield of the AES\_CR register.*

*When transiting from the header phase to the final phase, the AES peripheral must not be disabled, otherwise the result is wrong.*

*Application must mask the authentication tag output with tag length to obtain a valid tag.*

### Suspend/resume operations in CCM mode

**To suspend the authentication** of the associated data and payload (GCMPPH[1:0]= 01), proceed as follows. Suspending the message during the encryption/decryption phase is described in [Section 28.4.9: AES counter \(CTR\) mode on page 840](#).

1. If DMA is used, stop the AES DMA transfers to the IN FIFO by clearing the DMAINEN bit of the AES\_CR register. If DMA is not used, make sure that the current computation is completed, which is indicated by the CCF flag of the AES\_SR register set to 1.
2. Clear the CCF flag of the AES\_SR register, by setting to 1 the CCFC bit of the AES\_CR register.
3. Save the AES\_SUSPxR registers (where x is from 0 to 7) in the memory.
4. Save the AES\_IVRx registers, as during the data processing they changed from their initial values.
5. Disable the AES peripheral, by clearing the bit EN of the AES\_CR register.
6. Save the current AES configuration in the memory, excluding the initialization vector registers AES\_IVRx. Key registers do not need to be saved as the original key value is known by the application.
7. If DMA is used, save the DMA controller status (pointers for IN data transfers, number of remaining bytes, and so on).

**To resume the authentication** of the associated data and payload (GCMPh[1:0]= 01 or 11), proceed as follows:

1. If DMA is used, configure the DMA controller in order to complete the rest of the FIFO IN transfers.
2. Ensure that AES processor is disabled (the EN bit of the AES\_CR register must be 0).
3. Write the suspend register values, previously saved in the memory, back into their corresponding AES\_SUSPxR registers (where x is from 0 to 7).
4. Write the initialization vector register values, previously saved in the memory, back into their corresponding AES\_IVRx registers.
5. Restore the initial setting values in the AES\_CR and AES\_KEYRx registers.
6. Enable the AES peripheral by setting the EN bit of the AES\_CR register.
7. If DMA is used, enable AES DMA requests by setting the DMAINEN bit of the AES\_CR register.

*Note:* In CCM mode the MODE[1:0] bitfield settings 01 and 11 (key derivation) are forbidden.

### 28.4.13 AES data registers and data swapping

#### Data input and output

A 128-bit data block is entered into the AES peripheral with four successive 32-bit word writes into the AES\_DINR register (bitfield DIN[127:0]), the most significant word (bits [127:96]) first, the least significant word (bits [31:0]) last.

A 128-bit data block is retrieved from the AES peripheral with four successive 32-bit word reads from the AES\_DOUTR register (bitfield DOUT[127:0]), the most significant word (bits [127:96]) first, the least significant word (bits [31:0]) last.

The 32-bit data word for AES\_DINR register or from AES\_DOUTR register is organized in big endian order, that is:

- the most significant byte of a word to write into AES\_DINR must be put on the lowest address out of the four adjacent memory locations keeping the word to write, or
- the most significant byte of a word read from AES\_DOUTR goes to the lowest address out of the four adjacent memory locations receiving the word

For using DMA for input data block write into AES, the four words of the input block must be stored in the memory consecutively and in big-endian order, that is, the most significant word on the lowest address. See [Section 28.4.16: AES DMA interface](#).

#### Data swapping

The AES peripheral can be configured to perform a bit-, a byte-, a half-word-, or no swapping on the input data word in the AES\_DINR register, before loading it to the AES processing core, and on the data output from the AES processing core, before sending it to the AES\_DOUTR register. The choice depends on the type of data. For example, a byte swapping is used for an ASCII text stream.

The data swap type is selected through the DATATYPE[1:0] bitfield of the AES\_CR register. The selection applies both to the input and the output of the AES core.

For different data swap types, [Figure 216](#) shows the construction of AES processing core input buffer data P127..0, from the input data entered through the AES\_DINR register, or the construction of the output data available through the AES\_DOUTR register, from the AES processing core output buffer data P127..0.

Figure 216. 128-bit block construction with respect to data swap

**Note:** The data in AES key registers (AES\_KEYRx) and initialization registers (AES\_IVRx) are not sensitive to the swap mode selection.

### Data padding

Figure 216 also gives an example of memory data block padding with zeros such that the zeroed bits after the data swap form a contiguous zone at the MSB end of the AES core input buffer. The example shows the padding of an input data block containing:

- 48 message bits, with DATATYPE[1:0] = 01
- 56 message bits, with DATATYPE[1:0] = 10
- 34 message bits, with DATATYPE[1:0] = 11

### 28.4.14 AES key registers

The AES\_KEYRx registers store the encryption or decryption key bitfield KEY[127:0] or KEY[255:0]. The data to write to or to read from each register is organized in the memory in little-endian order, that is, with most significant byte on the highest address.

The key is spread over the eight registers as shown in [Table 184](#).

**Table 184. Key endianness in AES\_KEYRx registers (128- or 256-bit key length)**

| AES_KEYR7<br>[31:0] | AES_KEYR6<br>[31:0] | AES_KEYR5<br>[31:0] | AES_KEYR4<br>[31:0] | AES_KEYR3<br>[31:0] | AES_KEYR2<br>[31:0] | AES_KEYR1<br>[31:0] | AES_KEYR0<br>[31:0] |
|---------------------|---------------------|---------------------|---------------------|---------------------|---------------------|---------------------|---------------------|
| -                   | -                   | -                   | -                   | KEY[127:96]         | KEY[95:64]          | KEY[63:32]          | KEY[31:0]           |
| KEY[255:224]        | KEY[223:192]        | KEY[191:160]        | KEY[159:128]        | KEY[127:96]         | KEY[95:64]          | KEY[63:32]          | KEY[31:0]           |

The key for encryption or decryption may be written into these registers when the AES peripheral is disabled.

The key registers are not affected by the data swapping controlled by DATATYPE[1:0] bitfield of the AES\_CR register.

### 28.4.15 AES initialization vector registers

The four AES\_IVRx registers keep the initialization vector input bitfield IVI[127:0]. The data to write to or to read from each register is organized in the memory in little-endian order, that is, with most significant byte on the highest address. The registers are also ordered from lowest address (AES\_IVR0) to highest address (AES\_IVR3).

The signification of data in the bitfield depends on the chaining mode selected. When used, the bitfield is updated upon each computation cycle of the AES core.

Write operations to the AES\_IVRx registers when the AES peripheral is enabled have no effect to the register contents. For modifying the contents of the AES\_IVRx registers, the EN bit of the AES\_CR register must first be cleared.

Reading the AES\_IVRx registers returns the latest counter value (useful for managing suspend mode).

The AES\_IVRx registers are not affected by the data swapping feature controlled by the DATATYPE[1:0] bitfield of the CRYPT\_CR register.

### 28.4.16 AES DMA interface

The AES peripheral provides an interface to connect to the DMA (direct memory access) controller. The DMA operation is controlled through the AES\_CR register.

#### Data input using DMA

Setting the DMAINEN bit of the AES\_CR register enables DMA writing into AES. The AES peripheral then initiates a DMA request during the input phase each time it requires a word to be written to the AES\_DINR register. It asserts four DMA requests to transfer one 128-bit (four-word) input data block from memory, as shown in [Figure 217](#).

See [Table 185](#) for recommended DMA configuration.

Table 185. DMA channel configuration for memory-to-AES data transfer

| DMA channel control register field         | Recommended configuration                                                                                                                                                                                                                                       |
|--------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Transfer size                              | Message length: a multiple of 128 bits.<br>According to the algorithm and the mode selected, special padding/ ciphertext stealing might be required. Refer to <a href="#">Section 28.4.6: AES ciphertext stealing and data padding on page 833</a> for details. |
| Source burst size (memory)                 | Single                                                                                                                                                                                                                                                          |
| Destination burst size (peripheral)        | Single                                                                                                                                                                                                                                                          |
| DMA FIFO size                              | AES FIFO_size = 4 bytes.                                                                                                                                                                                                                                        |
| Source transfer width (memory)             | 32-bit words                                                                                                                                                                                                                                                    |
| Destination transfer width (peripheral)    | 32-bit words                                                                                                                                                                                                                                                    |
| Source address increment (memory)          | Yes, after each 32-bit transfer                                                                                                                                                                                                                                 |
| Destination address increment (peripheral) | Fixed address of AES_DINR (no increment)                                                                                                                                                                                                                        |

Figure 217. DMA transfer of a 128-bit data block during input phase

### Data output using DMA

Setting the DMAOUTEN bit of the AES\_CR register enables DMA reading from AES. The AES peripheral then initiates a DMA request during the Output phase each time it requires a word to be read from the AES\_DOUTR register. It asserts four DMA requests to transfer one 128-bit (four-word) output data block to memory, as shown in [Figure 218](#).

See [Table 186](#) for recommended DMA configuration.

Table 186. DMA channel configuration for AES-to-memory data transfer

| DMA channel control register field     | Recommended configuration                                                                                                   |
|----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| Transfer size                          | It is the message length multiple of AES block size (4 words). According to the case extra bytes will have to be discarded. |
| Source burst size (peripheral)         | Single                                                                                                                      |
| Destination burst size (memory)        | Single                                                                                                                      |
| DMA FIFO size                          | AES FIFO_size = 4 bytes                                                                                                     |
| Source transfer width (peripheral)     | 32-bit words                                                                                                                |
| Destination transfer width (memory)    | 32-bit words                                                                                                                |
| Source address increment (peripheral)  | Fixed address of AES_DINR (no increment)                                                                                    |
| Destination address increment (memory) | Yes, after each 32-bit transfer                                                                                             |

Figure 218. DMA transfer of a 128-bit data block during output phase

### DMA operation in different operating modes

DMA operations are usable when Mode 1 (encryption) or Mode 3 (decryption) are selected via the MODE[1:0] bitfield of the register AES\_CR. As in Mode 2 (key derivation) the AES\_KEYRx registers must be written by software, enabling the DMA transfer through the DMAINEN and DMAOUTEN bits of the AES\_CR register have no effect in that mode.

DMA single requests are generated by AES until it is disabled. So, after the data output phase at the end of processing of a 128-bit data block, AES switches automatically to a new data input phase for the next data block, if any.

When the data transferring between AES and memory is managed by DMA, the CCF flag is not relevant and can be ignored (left set) by software. It must only be cleared when

transiting back to data transferring managed by software. See [Suspend/resume operations in ECB/CBC modes](#) in [Section 28.4.8: AES basic chaining modes \(ECB, CBC\)](#) as example.

### 28.4.17 AES error management

The read error flag (RDERR) and write error flag (WRERR) of the AES\_SR register are set when an unexpected read or write operation, respectively, is detected. An interrupt can be generated if the error interrupt enable (ERRIE) bit of the AES\_CR register is set. For more details, refer to [Section 28.5: AES interrupts](#).

*Note:* AES is not disabled after an error detection and continues processing.

AES can be re-initialized at any moment by clearing then setting the EN bit of the AES\_CR register.

#### Read error flag (RDERR)

When an unexpected read operation is detected during the computation phase or during the input phase, the AES read error flag (RDERR) is set in the AES\_SR register. An interrupt is generated if the ERRIE bit of the AES\_CR register is set.

The RDERR flag is cleared by setting the corresponding ERRC bit of the AES\_CR register.

#### Write error flag (WDERR)

When an unexpected write operation is detected during the computation phase or during the output phase, the AES write error flag (WRERR) is set in the AES\_SR register. An interrupt is generated if the ERRIE bit of the AES\_CR register is set.

The WDERR flag is cleared by setting the corresponding ERRC bit of the AES\_CR register.

## 28.5 AES interrupts

There are three individual maskable interrupt sources generated by the AES peripheral, to signal the following events:

- computation completed
- read error, see [Section 28.4.17](#)
- write error, see [Section 28.4.17](#)

These three sources are combined into a common interrupt signal `aes_it` that connects to NVIC (nested vectored interrupt controller).

**Figure 219. AES interrupt signal generation**

Each AES interrupt source can individually be enabled/disabled, by setting/clearing the corresponding enable bit of the AES\_CR register. See [Figure 219](#).

The status of the individual maskable interrupt sources can be read from the AES\_SR register.

[Table 187](#) gives a summary of the interrupt sources, their event flags and enable bits.

**Table 187. AES interrupt requests**

| AES interrupt event        | Event flag | Enable bit |
|----------------------------|------------|------------|
| computation completed flag | CCF        | CCFIE      |
| read error flag            | RDERR      | ERRIE      |
| write error flag           | WRERR      | ERRIE      |

## 28.6 AES processing latency

The tables below summarize the latency to process a 128-bit block for each mode of operation.

**Table 188. Processing latency (in clock cycle) for ECB, CBC and CTR**

| Key size | Mode of operation                      | Algorithm     | Input phase | Computation phase | Output phase | Total      |
|----------|----------------------------------------|---------------|-------------|-------------------|--------------|------------|
| 128-bit  | Mode 1: Encryption                     | ECB, CBC, CTR | 8           | 202               | 4            | <b>214</b> |
|          | Mode 2: Key derivation                 | -             | -           | 80                | -            | <b>80</b>  |
|          | Mode 3: Decryption                     | ECB, CBC, CTR | 8           | 202               | 4            | <b>214</b> |
|          | Mode 4: Key derivation then decryption | ECB, CBC      | 8           | 276               | 4            | <b>288</b> |
| 256-bit  | Mode 1: Encryption                     | ECB, CBC, CTR | 8           | 286               | 4            | <b>298</b> |
|          | Mode 2: Key derivation                 | -             | -           | 109               | -            | <b>109</b> |
|          | Mode 3: Decryption                     | ECB, CBC, CTR | 8           | 286               | 4            | <b>298</b> |
|          | Mode 4: Key derivation then decryption | ECB, CBC      | 8           | 380               | 4            | <b>392</b> |

**Table 189. Processing latency for GCM and CCM (in clock cycle)**

| Key size | Mode of operation                         | Algorithm          | Init Phase | Header phase | Payload phase | Tag phase |
|----------|-------------------------------------------|--------------------|------------|--------------|---------------|-----------|
| 128-bit  | Mode 1: Encryption/<br>Mode 3: Decryption | GCM                | 215        | 67           | 202           | 202       |
|          | -                                         | CCM authentication | -          | 206          | -             | 202       |
| 256-bit  | Mode 1: Encryption/<br>Mode 3: Decryption | GCM                | 299        | 67           | 286           | 286       |
|          | -                                         | CCM authentication | -          | 290          | -             | 286       |

**Note:** Data insertion can include wait states forced by AES on the AHB bus (maximum 3 cycles, typical 1 cycle). This applies to all header/payload/tag phases.

## 28.7 AES registers

### 28.7.1 AES control register (AES\_CR)

Address offset: 0x00

Reset value: 0x0000 0000

|      |             |      |              |             |       |       |      |      |            |      |           |      |               |      |              |

| 15   | 14          | 13   | 12           | 11          | 10    | 9     | 8    | 7    | 6          | 5    | 4         | 3    | 2             | 1    | 0            |
| Res. | GCM PH[1:0] |      | DMAO<br>UTEN | DMAIN<br>EN | ERRIE | CCFIE | ERRC | CCFC | CHMOD[1:0] |      | MODE[1:0] |      | DATATYPE[1:0] |      | EN           |
|      | rw          | rw   | rw           | rw          | rw    | rw    | rw   | rw   | rw         | rw   | rw        | rw   | rw            | rw   | rw           |

Bits 31:19 Reserved, must be kept at zero

Bit 18 **KEYSIZE**: Key size selection

This bitfield defines the length of the key used in the AES cryptographic core, in bits:

0: 128

1: 256

The bit value change is allowed only when AES is disabled, so as to avoid an unpredictable behavior.

Bit 17 Reserved, must be kept at zero

Bit 16 **CHMOD[2]**: Chaining mode selection, bit [2]

Refer to the bits [5:6] of the register for the description of the CHMOD[2:0] bitfield

Bit 15 Reserved, must be kept at zero

Bits 14:13 **GCM PH[1:0]**: GCM or CCM phase selection

This bitfield selects the phase of GCM, GMAC or CCM algorithm:

00: Init phase

01: Header phase

10: Payload phase

11: Final phase

The bitfield has no effect if other than GCM, GMAC or CCM algorithms are selected (through the ALGOMODE bitfield).

**Bit 12 DMAOUTEN:** DMA output enable

This bit enables/disables data transferring with DMA, in the output phase:

0: Disable

1: Enable

When the bit is set, DMA requests are automatically generated by AES during the output data phase. This feature is only effective when Mode 1 or Mode 3 is selected through the MODE[1:0] bitfield. It is not effective for Mode 2 (key derivation).

Usage of DMA with Mode 4 (single decryption) is not recommended.

**Bit 11 DMAINEN:** DMA input enable

This bit enables/disables data transferring with DMA, in the input phase:

0: Disable

1: Enable

When the bit is set, DMA requests are automatically generated by AES during the input data phase. This feature is only effective when Mode 1 or Mode 3 is selected through the MODE[1:0] bitfield. It is not effective for Mode 2 (key derivation).

Usage of DMA with Mode 4 (single decryption) is not recommended.

**Bit 10 ERRIE:** Error interrupt enable

This bit enables or disables (masks) the AES interrupt generation when RDERR and/or WRERR is set:

0: Disable (mask)

1: Enable

**Bit 9 CCFIE:** CCF interrupt enable

This bit enables or disables (masks) the AES interrupt generation when CCF (computation complete flag) is set:

0: Disable (mask)

1: Enable

**Bit 8 ERRC:** Error flag clear

Upon written to 1, this bit clears the RDERR and WRERR error flags in the AES\_SR register:

0: No effect

1: Clear RDERR and WRERR flags

Reading the flag always returns zero.

**Bit 7 CCFC:** Computation complete flag clear

Upon written to 1, this bit clears the computation complete flag (CCF) in the AES\_SR register:

0: No effect

1: Clear CCF

Reading the flag always returns zero.

Bits 6:5 **CHMOD[1:0]**: Chaining mode selection, bits [1:0]

These bits, together with the bit CHMOD[2] (see bit 16 of this register), form CHMOD[2:0] bitfield that selects the AES chaining mode:

- 000: Electronic codebook (ECB)
- 001: Cipher-Block Chaining (CBC)
- 010: Counter Mode (CTR)
- 011: Galois Counter Mode (GCM) and Galois Message Authentication Code (GMAC)
- 100: Counter with CBC-MAC (CCM)
- >100: Reserved

The bitfield value change is allowed only when AES is disabled, so as to avoid an unpredictable behavior.

Bits 4:3 **MODE[1:0]**: AES operating mode

This bitfield selects the AES operating mode:

- 00: Mode 1: encryption
- 01: Mode 2: key derivation (or key preparation for ECB/CBC decryption)
- 10: Mode 3: decryption
- 11: Mode 4: key derivation then single decryption

The bitfield value change is allowed only when AES is disabled, so as to avoid an unpredictable behavior. Any attempt to selecting Mode 4 while either ECB or CBC chaining mode is not selected, defaults to effective selection of Mode 3. It is not possible to select a Mode 3 following a Mode 4.

Bits 2:1 **DATATYPE[1:0]**: Data type selection

This bitfield defines the format of data written in the AES\_DINR register or read from the AES\_DOUTR register, through selecting the mode of data swapping:

- 00: None
- 01: Half-word (16-bit)
- 10: Byte (8-bit)
- 11: Bit

For more details, refer to [Section 28.4.13: .AES data registers and data swapping](#).

The bitfield value change is allowed only when AES is disabled, so as to avoid an unpredictable behavior.

Bit 0 **EN**: AES enable

This bit enables/disables the AES peripheral:

- 0: Disable
- 1: Enable

At any moment, clearing then setting the bit re-initializes the AES peripheral.

This bit is automatically cleared by hardware when the key preparation process ends (Mode 2).

## 28.7.2 AES status register (AES\_SR)

Address offset: 0x04

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |      |      |      |      |       |       |      |
|------|------|------|------|------|------|------|------|------|------|------|------|------|-------|-------|------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18    | 17    | 16   |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.  | Res.  | Res. |
| r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r     | r     | r    |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2     | 1     | 0    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | BUSY | WRERR | RDERR | CCF  |
| r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r     | r     | r    |

Bits 31:4 Reserved, must be kept at zero

Bit 3 **BUSY**: Busy

This flag indicates whether AES is idle or busy during GCM payload **encryption** phase:

0: Idle

1: Busy

The flag is controlled by hardware. When the flag indicates “idle”, the current message processing may be suspended to process a higher-priority message.

This flag is effective only in GCM payload encryption phase. In other chaining modes, or in GCM phases other than payload encryption, the flag must be ignored.

**Bit 2 WRERR:** Write error

This flag indicates the detection of an unexpected write operation to the AES\_DINR register (during computation or data output phase):

0: Not detected  
1: Detected

The flag is set by hardware. It is cleared by software upon setting the ERRC bit of the AES\_CR register.

Upon the flag setting, an interrupt is generated if enabled through the ERRIE bit of the AES\_CR register.

The flag setting has no impact on the AES operation.

The flag is not effective when key derivation mode, or GCM/CCM Init phase is selected.

**Bit 1 RDERR:** Read error flag

This flag indicates the detection of an unexpected read operation from the AES\_DOUTR register (during computation or data input phase):

0: Not detected  
1: Detected

The flag is set by hardware. It is cleared by software upon setting the ERRC bit of the AES\_CR register.

Upon the flag setting, an interrupt is generated if enabled through the ERRIE bit of the AES\_CR register.

The flag setting has no impact on the AES operation.

The flag is not effective when key derivation mode, nor GCM/CCM init/header phase is selected.

**Bit 0 CCF:** Computation completed flag

This flag indicates whether the computation is completed:

0: Not completed  
1: Completed

The flag is set by hardware upon the completion of the computation. It is cleared by software, upon setting the CCFC bit of the AES\_CR register.

Upon the flag setting, an interrupt is generated if enabled through the CCFIE bit of the AES\_CR register.

The flag is significant only when the DMAOUTEN bit is 0. It may stay high when DMA\_EN is 1.

**28.7.3 AES data input register (AES\_DINR)**

Address offset: 0x08

Reset value: 0x0000 0000

Only 32-bit access type is supported.

| 31             | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|----------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| DIN[x+31:x+16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw             | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
| 15             | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| DIN[x+15:x]    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw             | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:0 **DIN[x+31:x]**: One of four 32-bit words of a 128-bit input data block being written into the peripheral

This bitfield feeds a 32-bit input buffer. A 4-fold sequential write to this bitfield during the input phase virtually writes a complete 128-bit block of input data to the AES peripheral. Upon each write, the data from the input buffer are handled by the data swap block according to the DATATYPE[1:0] bitfield, then written into the AES core 128-bit input buffer.

The substitution for “x”, from the first to the fourth write operation, is: 96, 64, 32, and 0. In other words, data from the first to the fourth write operation are: DIN[127:96], DIN[95:64], DIN[63:32], and DIN[31:0].

The data signification of the input data block depends on the AES operating mode:

- **Mode 1** (encryption): plaintext
- **Mode 2** (key derivation): the bitfield is not used (AES\_KEYRx registers used for input)
- **Mode 3** (decryption) and **Mode 4** (key derivation then single decryption): ciphertext

The data swap operation is described in [Section 28.4.13: .AES data registers and data swapping on page 854](#).

## 28.7.4 AES data output register (AES\_DOUTR)

Address offset: 0x0C

Reset value: 0x0000 0000

Only 32-bit access type is supported.

|                 |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

| r               | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  |
| 15              | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| DOUT[x+15:0]    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| r               | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  |

Bits 31:0 **DOUT[x+31:x]**: One of four 32-bit words of a 128-bit output data block being read from the peripheral

This bitfield fetches a 32-bit output buffer. A 4-fold sequential read of this bitfield, upon the computation completion (CCF set), virtually reads a complete 128-bit block of output data from the AES peripheral. Before reaching the output buffer, the data produced by the AES core are handled by the data swap block according to the DATATYPE[1:0] bitfield.

The substitution for DOUT[x+31:x], from the first to the fourth read operation, is: 96, 64, 32, and 0. In other words, data from the first to the fourth read operation are: DOUT[127:96], DOUT[95:64], DOUT[63:32], and DOUT[31:0].

The data signification of the output data block depends on the AES operating mode:

- **Mode 1** (encryption): ciphertext
- **Mode 2** (key derivation): the bitfield is not used (AES\_KEYRx registers used for output).
- **Mode 3** (decryption) and **Mode 4** (key derivation then single decryption): plaintext

The data swap operation is described in [Section 28.4.13: .AES data registers and data swapping on page 854](#).

## 28.7.5 AES key register 0 (AES\_KEYR0)

Address offset: 0x10

Reset value: 0x0000 0000

|            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31         | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| KEY[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw         | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| KEY[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw         | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:0 **KEY[31:0]**: Cryptographic key, bits [31:0]

This bitfield contains the bits [31:0] of the AES encryption or decryption key, depending on the operating mode:

- In **Mode 1** (encryption), **Mode 2** (key derivation) and **Mode 4** (key derivation then single decryption): the value to write into the bitfield is the encryption key.
- In **Mode 3** (decryption): the value to write into the bitfield is the encryption key to be derived before being used for decryption. After writing the encryption key into the bitfield, its reading before enabling AES returns the same value. Its reading after enabling AES and after the CCF flag is set returns the decryption key derived from the encryption key.

*Note:* In mode 4 (key derivation then decryption) the bitfield always contains the encryption key.

The AES\_KEYRx registers may be written only when the AES peripheral is disabled.

Refer to [Section 28.4.14: AES key registers on page 856](#) for more details.

## 28.7.6 AES key register 1 (AES\_KEYR1)

Address offset: 0x14

Reset value: 0x0000 0000

|            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31         | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| KEY[63:48] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw         | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| KEY[47:32] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw         | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:0 **KEY[63:32]**: Cryptographic key, bits [63:32]

Refer to the AES\_KEYR0 register for description of the KEY[255:0] bitfield.

## 28.7.7 AES key register 2 (AES\_KEYR2)

Address offset: 0x18

Reset value: 0x0000 0000

|            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31         | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| KEY[95:80] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw         | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| KEY[79:64] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw         | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:0 **KEY[95:64]**: Cryptographic key, bits [95:64]

Refer to the AES\_KEYR0 register for description of the KEY[255:0] bitfield.

### 28.7.8 AES key register 3 (AES\_KEYR3)

Address offset: 0x1C

Reset value: 0x0000 0000

|              |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|--------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31           | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| KEY[127:112] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw           | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
| 15           | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| KEY[111:96]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw           | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:0 **KEY[127:96]**: Cryptographic key, bits [127:96]

Refer to the AES\_KEYR0 register for description of the KEY[255:0] bitfield.

### 28.7.9 AES initialization vector register 0 (AES\_IVR0)

Address offset: 0x20

Reset value: 0x0000 0000

|            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31         | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| IVI[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw         | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| IVI[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw         | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:0 **IVI[31:0]**: Initialization vector input, bits [31:0]

Refer to [Section 28.4.15: AES initialization vector registers on page 856](#) for description of the IVI[127:0] bitfield.

The initialization vector is only used in chaining modes other than ECB.

The initialization vector may be written only when the AES peripheral is disabled.

### 28.7.10 AES initialization vector register 1 (AES\_IVR1)

Address offset: 0x24

Reset value: 0x0000 0000

|            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31         | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| IVI[63:48] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw         | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| IVI[47:32] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw         | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:0 **IVI[63:32]**: Initialization vector input, bits [63:32]

Refer to [Section 28.4.15: AES initialization vector registers on page 856](#) for description of the IVI[127:0] bitfield.

The initialization vector is only used in chaining modes other than ECB.

The initialization vector may be written only when the AES peripheral is disabled.

### 28.7.11 AES initialization vector register 2 (AES\_IVR2)

Address offset: 0x28

Reset value: 0x0000 0000

|            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31         | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| IVI[95:80] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw         | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| IVI[79:64] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw         | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:0 **IVI[95:64]**: Initialization vector input, bits [95:64]

Refer to [Section 28.4.15: AES initialization vector registers on page 856](#) for description of the IVI[127:0] bitfield.

The initialization vector is only used in chaining modes other than ECB.

The initialization vector may be written only when the AES peripheral is disabled.

### 28.7.12 AES initialization vector register 3 (AES\_IVR3)

Address offset: 0x2C

Reset value: 0x0000 0000

|              |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|--------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31           | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| IVI[127:112] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw           | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
| 15           | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| IVI[111:96]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw           | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:0 **IVI[127:96]**: Initialization vector input, bits [127:96]

Refer to [Section 28.4.15: AES initialization vector registers on page 856](#) for description of the IVI[127:0] bitfield.

The initialization vector is only used in chaining modes other than ECB.

The initialization vector may be written only when the AES peripheral is disabled.

### 28.7.13 AES key register 4 (AES\_KEYR4)

Address offset: 0x30

Reset value: 0x0000 0000

|              |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|--------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31           | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| KEY[159:144] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw           | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
| 15           | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| KEY[143:128] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw           | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:0 **KEY[159:128]**: Cryptographic key, bits [159:128]

Refer to the AES\_KEYR0 register for description of the KEY[255:0] bitfield.

### 28.7.14 AES key register 5 (AES\_KEYR5)

Address offset: 0x34

Reset value: 0x0000 0000

|              |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|--------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31           | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| KEY[191:176] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw           | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
| 15           | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| KEY[175:160] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw           | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:0 **KEY[191:160]**: Cryptographic key, bits [191:160]

Refer to the AES\_KEYR0 register for description of the KEY[255:0] bitfield.

### 28.7.15 AES key register 6 (AES\_KEYR6)

Address offset: 0x38

Reset value: 0x0000 0000

|              |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|--------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31           | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| KEY[223:208] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw           | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
| 15           | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| KEY[207:192] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw           | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:0 **KEY[223:192]**: Cryptographic key, bits [223:192]

Refer to the AES\_KEYR0 register for description of the KEY[255:0] bitfield.

### 28.7.16 AES key register 7 (AES\_KEYR7)

Address offset: 0x3C

Reset value: 0x0000 0000

|              |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|--------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31           | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| KEY[255:240] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW           | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |
| 15           | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| KEY[239:224] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW           | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 31:0 **KEY[255:224]**: Cryptographic key, bits [255:224]

Refer to the AES\_KEYR0 register for description of the KEY[255:0] bitfield.

**Note:** *The key registers from 4 to 7 are used only when the key length of 256 bits is selected. They have no effect when the key length of 128 bits is selected (only key registers 0 to 3 are used in that case).*

### 28.7.17 AES suspend registers (AES\_SUSPxR)

Address offset: 0x040 + x \* 0x4, (x = 0 to 7)

Reset value: 0x0000 0000

These registers contain the complete internal register states of the AES processor when the AES processing of the current task is suspended to process a higher-priority task.

Upon suspend, the software reads and saves the AES\_SUSPxR register contents (where x is from 0 to 7) into memory, before using the AES processor for the higher-priority task.

Upon completion, the software restores the saved contents back into the corresponding suspend registers, before resuming the original task.

**Note:** *These registers are used only when GCM, GMAC, or CCM chaining mode is selected. These registers can be read only when AES is enabled. Reading these registers while AES is disabled returns 0x0000 0000.*

Bits 31:0 **SUSPx**: AES suspend

Upon suspend operation, this bitfield of every AES\_SUSPxR register takes the value of one of internal AES registers.

## 28.7.18 AES register map

Table 190. AES register map and reset values

| Offset | Register                  | 31           | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18      | 17   | 16       | 15   | 14   | 13         | 12   | 11       | 10      | 9     | 8     | 7    | 6    | 5    | 4          | 3    | 2         | 1     | 0             |     |

Refer to [Section 2.2 on page 75](#) for the register boundary addresses.

## 29 Hash processor (HASH)

This section applies to STM32L4Ax devices only.

### 29.1 Introduction

The hash processor is a fully compliant implementation of the secure hash algorithm (SHA-1, SHA2-224, SHA2-256), the MD5 (message-digest algorithm 5) hash algorithm and the HMAC (keyed-hash message authentication code) algorithm. HMAC is suitable for applications requiring message authentication.

The hash processor computes FIPS (Federal Information Processing Standards) approved digests of length of 160, 224, 256 bits, for messages of up to  $(2^{64} - 1)$  bits. It also computes 128-bit digests for the MD5 algorithm.

### 29.2 HASH main features

- Suitable for data authentication applications, compliant with:
  - Federal Information Processing Standards Publication FIPS PUB 180-4, *Secure Hash Standard* (SHA-1 and SHA-2 family)
  - Federal Information Processing Standards Publication FIPS PUB 186-4, *Digital Signature Standard (DSS)*
  - Internet Engineering Task Force (IETF) Request For Comments RFC 1321, *MD5 Message-Digest Algorithm*
  - Internet Engineering Task Force (IETF) Request For Comments RFC 2104, *HMAC: Keyed-Hashing for Message Authentication* and Federal Information Processing Standards Publication FIPS PUB 198-1, *The Keyed-Hash Message Authentication Code (HMAC)*
- Fast computation of SHA-1, SHA2-224, SHA2-256, and MD5
  - 82 (respectively 66) clock cycles for processing one 512-bit block of data using SHA-1 (respectively SHA2-256) algorithm
  - 66 clock cycles for processing one 512-bit block of data using MD5 algorithm
- Corresponding 32-bit words of the digest from consecutive message blocks are added to each other to form the digest of the whole message
  - Automatic 32-bit words swapping to comply with the internal little-endian representation of the input bit-string
  - Word swapping supported: bits, bytes, half-words and 32-bit words
- Automatic padding to complete the input bit string to fit digest minimum block size of 512 bits ( $16 \times 32$  bits)
- Single 32-bit input register associated to an internal input FIFO, corresponding to one block size
- AHB slave peripheral, accessible through 32-bit word accesses only (else an AHB error is generated)
- $8 \times 32$ -bit words (H0 to H7) for output message digest
- Automatic data flow control with support of direct memory access (DMA) using one channel.

- Only single DMA transfers are supported
- Interruptible message digest computation, on a per-block basis
  - Re-loadable digest registers
  - Hashing computation suspend/resume mechanism, including DMA

## 29.3 HASH implementation

The devices have a single instance of HASH peripheral.

## 29.4 HASH functional description

### 29.4.1 HASH block diagram

*Figure 220* shows the block diagram of the hash processor.

**Figure 220. HASH block diagram**

## 29.4.2 HASH internal signals

*Table 191* describes a list of useful to know internal signals available at HASH level, not at product level (on pads).

**Table 191. HASH internal input/output signals**

| Signal name | Signal type          | Description                             |
|-------------|----------------------|-----------------------------------------|
| hash_hclk   | digital input        | AHB bus clock                           |
| hash_it     | digital output       | Hash processor global interrupt request |
| hash_dma    | digital input/output | DMA transfer request/ acknowledge       |

## 29.4.3 About secure hash algorithms

The hash processor is a fully compliant implementation of the secure hash algorithm defined by FIPS PUB 180-4 standard and the IETF RFC1321 publication (MD5).

With each algorithm, the HASH computes a condensed representation of a message or data file. More specifically, when a message of any length below  $2^{64}$  bits is provided on input, the HASH processing core produces respectively a fixed-length output string called a message digest, defined as follows:

- For MD5 digest size is 128-bit
- For SHA-1 digest size is 160-bit
- For SHA2-224 and SHA2-256, the digest size is 224 bits and 256 bits, respectively

The message digest can then be processed with a digital signature algorithm in order to generate or verify the signature for the message.

Signing the message digest rather than the message often improves the efficiency of the process because the message digest is usually much smaller in size than the message. The verifier of a digital signature has to use the same hash algorithm as the one used by the creator of the digital signature.

The SHA-2 functions supported by the hash processor are qualified as “secure” by NIST because it is computationally infeasible to find a message that corresponds to a given message digest, or to find two different messages that produce the same message digest (SHA-1 does not qualify as secure since February 2017). Any change to a message in transit, with very high probability, results in a different message digest, and the signature fails to verify.

## 29.4.4 Message data feeding

The message (or data file) to be processed by the HASH is considered as a bit string. Per FIPS PUB 180-4 standard this message bit string grows from left to right, with hexadecimal words expressed in “big-endian” convention, so that within each word, the most significant bit is stored in the left-most bit position. For example message string “abc” with a bit string representation of “01100001 01100010 01100011” is represented by a 32-bit word 0x00636261, and 8-bit words 0x61626300.

Data are entered into the HASH one 32-bit word at a time, by writing them into the HASH\_DIN register. The current contents of the HASH\_DIN register are transferred to the 16 words input FIFO each time the register is written with new data. Hence HASH\_DIN and the FIFO form a seventeen 32-bit words length FIFO (named the IN buffer).

In accordance to the kind of data to be processed (e.g. byte swapping when data are ASCII text stream) there must be a bit, byte, half-word or no swapping operation to be performed on data from the input FIFO before entering the little-endian hash processing core.

Figure 221 shows how the hash processing core 32-bit data block M0...31 is constructed from one 32-bit words popped into input FIFO by the driver, according to the DATATYPE bitfield in the HASH control register (HASH\_CR).

HASH\_DIN data endianness when bit swapping is disabled (DATATYPE = 00) can be described as following: the least significant bit of the message has to be at MSB position in the first word entered into the hash processor, the 32nd bit of the bit string has to be at MSB position in the second word entered into the hash processor and so on.

Figure 221. Message data swapping feature

### 29.4.5 Message digest computing

The hash processor sequentially processes several blocks when computing the message digest. For MD5, SHA1 and SHA2, the block size is 512 bits.

Each time the DMA or the CPU writes a block to the hash processor, the HASH automatically starts computing the message digest. This operation is known as partial digest computation.

As described in [Section 29.4.4: Message data feeding](#), the message to be processed is entered into the HASH 32-bit word at a time, writing to the HASH\_DIN register to fill the input FIFO.

In order to perform the hash computation on this data below sequence must be used by the application:

1. Initialize the hash processor using the HASH\_CR register:
  - a) Select the right algorithm using the ALGO bitfield. If needed program the correct swapping operation on the message input words using DATATYPE bitfield in HASH\_CR.
  - b) When the HMAC mode is required, set the MODE bit, as well as the LKEY bit if the HMAC key size is greater than the known block size of the algorithm (else keep LKEY cleared). Refer to [Section 29.4.7: HMAC operation](#) for details.
  - c) Update NBLW[4:0] to define the number of valid bits in last word of the message if it is different from 32 bits. NBLW[4:0] information are used to correctly perform the automatic message padding before the final message digest computation.
2. Complete the initialization by setting to 1 the INIT bit in HASH\_CR. Also set the bit DMAE to 1 if data are transferred via DMA.

**Caution:** When programming step 2, it is important to set up before or at the same time the correct configuration values (ALGO, DATATYPE, HMAC mode, key length, NBLW[4:0]).

3. Start filling data by writing to HASH\_DIN register, unless data are automatically: transferred via DMA. Note that the processing of a block can start only once the last value of the block has entered the input FIFO. The way the partial or final digest computation is managed depends on the way data are fed into the processor:
  - a) When data are filled by software:
    - Partial digest computation are triggered each time the application writes the first word of the next block. Once the processor is ready again (DINIS = 1 in HASH\_SR), the software can write new data to HASH\_DIN. This mechanism avoids the introduction of wait states by the HASH.
    - The final digest computation is triggered when the last block is entered and the software writes the DCAL bit to 1. If the message length is not an exact multiple of the block size, the NBLW[4:0] bitfield in HASH\_STR register must be written prior to writing DCAL bit (see [Section 29.4.6](#) for details).
  - b) When data are filled by DMA as a single DMA transfer (MDMAT bit = 0):
    - Partial digest computations are triggered automatically each time the FIFO is full. The final digest computation is triggered automatically when the last block has been transferred to the HASH\_DIN register (DCAL bit is set to 1 by hardware). If the message length is not an exact multiple of the block size, the NBLW[4:0] field

in HASH\_STR register must be written prior to enabling the DMA (see [Section 29.4.6](#) for details).

- c) When data are filled by DMA using multiple DMA transfers (MDMAT bit = 1):
  - Partial digest computations are triggered as for single DMA transfers. However the final digest computation is not triggered automatically when the last block has been transferred by DMA to the HASH\_DIN register (DCAL bit is not set to 1 by hardware). It allows the hash processor to receive a new DMA transfer as part of this digest computation. To launch the final digest computation, the software must set MDMAT bit to 0 before the last DMA transfer in order to trigger the final digest computation as it is done for single DMA transfers (see description before).
- 4. Once the digest computation is complete (DCIS = 1), the resulting digest can be read from the output registers as described in [Table 192](#).

**Table 192. Hash processor outputs**

| Algorithm | Valid output registers | Most significant bit | Digest size (in bits) |
|-----------|------------------------|----------------------|-----------------------|
| MD5       | HASH_H0 to HASH_H3     | HASH_H0[31]          | 128                   |
| SHA-1     | HASH_H0 to HASH_H4     | HASH_H0[31]          | 160                   |
| SHA2-224  | HASH_H0 to HASH_H6     | HASH_H0[31]          | 224                   |
| SHA2-256  | HASH_H0 to HASH_H7     |                      | 256                   |

For more information about HMAC detailed instructions, refer to [Section 29.4.7: HMAC operation](#).

## 29.4.6 Message padding

### Overview

When computing a condensed representation of a message, the process of feeding data into the hash processor (with automatic partial digest computation every block transfer) loops until the last bits of the original message are written to the HASH\_DIN register.

As the length (number of bits) of a message can be any integer value, the last word written to the hash processor may have a valid number of bits between 1 and 32. This number of valid bits in the last word, NBLW[4:0], has to be written to the HASH\_STR register, so that message padding is correctly performed before the final message digest computation.

### Padding processing

Detailed padding sequences with DMA enabled or disabled are described in [Section 29.4.5: Message digest computing](#).

### Padding example

As specified by Federal Information Processing Standards PUB 180-4, the message padding consists in appending a “1” followed by  $k$  “0”s, itself followed by a 64-bit integer that is equal to the length  $L$  in bits of the message. These three padding operations generate a padded message of length  $L + 1 + k + 64$ , which by construction is a multiple of 512 bits.

For the hash processor, the “1” is added to the last word written to the HASH\_DIN register at the bit position defined by the NBLW[4:0] bitfield, and the remaining upper bits are cleared (“0”s).

**Example from FIPS PUB180-4**

Let us assume that the original message is the ASCII binary-coded form of “abc”, of length L = 24:

```
byte 0    byte 1    byte 2    byte 3
01100001 01100010 01100011 UUUUUUUU
<-- 1st word written to HASH_DIN -->
```

NBLW[4:0] has to be loaded with the value 24: a “1” is appended at bit location 24 in the bit string (starting counting from left to right in the above bit string), which corresponds to bit 31 in the HASH\_DIN register (little-endian convention):

```
01100001 01100010 01100011 1UUUUUUU
```

Since L = 24, the number of bits in the above bit string is 25, and 423 “0” bits are appended, making now 448 bits.

This gives in hexadecimal (byte words in big-endian format):

```
61626380 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000018
```

The message length value, L, in two-word format (that is 00000000 00000018) is appended. Hence the final padded message in hexadecimal (byte words in big-endian format):

```
61626380 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000018
```

If the hash processor is programmed to swap byte within HASH\_DIN input register (DATATYPE = 10 in HASH\_CR), the above message has to be entered by following the below sequence:

1. **0xUU636261** is written to the HASH\_DIN register (where ‘U’ means don’t care).
2. **0x18** is written to the HASH\_STR register (the number of valid bits in the last word written to the HASH\_DIN register is 24, as the original message length is 24 bits).
3. **0x10** is written to the HASH\_STR register to start the message padding (described above) and then perform the digest computation.
4. The hash computing is complete with the message digest available in the HASH\_HRx registers (x = 0...4) for the SHA-1 algorithm. For this FIPS example, the expected value is as follows:

```
HASH_HR0 = 0xA9993E36
HASH_HR1 = 0x4706816A
HASH_HR2 = 0xBA3E2571
HASH_HR3 = 0x7850C26C
HASH_HR4 = 0x9CD0D89D
```

## 29.4.7 HMAC operation

### Overview

As specified by Internet Engineering Task Force RFC2104 and NIST FIPS PUB 198-1, the HMAC algorithm is used for message authentication by irreversibly binding the message being processed to a key chosen by the user. The algorithm consists of two nested hash operations:

$$\text{HMAC}(\text{message}) = \text{Hash}((\text{Key} \mid \text{pad}) \text{ XOR } \text{opad} \mid \text{Hash}((\text{Key} \mid \text{pad}) \text{ XOR } \text{ipad} \mid \text{message}))$$

where:

- **opad** =  $[0x5C]_n$  (outer pad) and **ipad** =  $[0x36]_n$  (inner pad)
- $[X]_n$  represents a repetition of  $X$   $n$  times, where  $n$  equal to the size of the underlying hash function data block ( $n = 64$  for 512-bit blocks).
- **pad** is a sequence of zeroes needed to extend the key to the length  $n$  defined above. If the key length is greater than  $n$ , the application must first hash the key using Hash() function and then use the resultant byte string as the actual key to HMAC.
- $\mid$  represents the concatenation operator.

*Note:* HMAC mode of the hash processor can be used with all supported algorithms.

### HMAC processing

Four different steps are required to compute the HMAC:

1. The software writes the INIT bit to 1 with the MODE bit at 1 and the ALGO bits set to the value corresponding to the desired algorithm. The LKEY bit must also be set to 1 if the key being used is longer than 64 bytes. In this case, as required by HMAC specifications, the hash processor uses the hash of the key instead of the real key.
2. The software provides the key to be used for the inner hash function, using the same mechanism as the message string loading, that is writing the key data into HASH\_DIN register then completing the transfer by writing DCAL bit to 1 and the correct NBLW[4:0] to HASH\_STR register.

*Note:* Endianness details can be found in [Section 29.4.4: Message data feeding](#).

3. Once the processor is ready again (DINIS = 1 in HASH\_SR), the software can write the message string to HASH\_DIN. When the last word of the last block is entered and the software writes DCAL bit to 1 in HASH\_STR register, the NBLW[4:0] bitfield must be written at the same time to a value different from zero if the message length is not an exact multiple of the block size. Note that the DMA can also be used to feed the message string, as described in [Section 29.4.4: Message data feeding](#).
4. Once the processor is ready again (DINIS = 1 in HASH\_SR), the software provides the key to be used for the outer hash function, writing the key data into HASH\_DIN register then completing the transfer by writing DCAL bit to 1 and the correct NBLW[4:0] to HASH\_STR register. The HMAC result can be found in the valid output registers (HASH\_HRx) as soon as DCIS bit is set to 1.

*Note:* The computation latency of the HMAC primitive depends on the lengths of the keys and message, as described in [Section 29.6: HASH processing time](#).

### HMAC example

Below is an example of HMAC SHA-1 algorithm (ALGO = 00 and MODE = 1 in HASH\_CR) as specified by NIST.

Let us assume that the original message is the ASCII binary-coded form of “**Sample message for keylen = blocklen**”, of length L = 34 bytes. If the HASH is programmed in no swapping mode (DATATYPE = 00 in HASH\_CR), the following data must be loaded sequentially into HASH\_DIN register:

1. **Inner hash key** input (length = 64, that is no padding), specified by NIST. As key length = 64, LKEY bit is set to 0 in HASH\_CR register  

```
00010203 04050607 08090A0B 0C0D0E0F 10111213 14151617
18191A1B 1C1D1E1F 20212223 24252627 28292A2B 2C2D2E2F
30313233 34353637 38393A3B 3C3D3E3F
```
2. **Message** input (length = 34, that is padding required). HASH\_STR must be set to 0x20 to start message padding and inner hash computation (see ‘U’ as don’t care)  

```
53616D70 6C65206D 65737361 67652066 6F72206B 65796C65
6E3D626C 6F636B6C 656EUUUU
```
3. **Outer hash key** input (length = 64, that is no padding). A key identical to the inner hash key is entered here.
4. **Final outer hash computing** is then performed by the HASH. The HMAC-SHA1 digest result is available in the HASH\_HRx registers (x = 0 to 4), as shown below:  

```
HASH_HR0 = 0x5FD596EE
HASH_HR1 = 0x78D5553C
HASH_HR2 = 0x8FF4E72D
HASH_HR3 = 0x266DFD19
HASH_HR4 = 0x2366DA29
```

## 29.4.8 HASH suspend/resume operations

### Overview

It is possible to interrupt a hash/HMAC operation to perform another processing with a higher priority. The interrupted process completes later when the higher-priority task has been processed, as shown in [Figure 222](#).

**Figure 222. HASH suspend/resume mechanism**

To do so, the context of the interrupted task must be saved from the HASH registers to memory, and then be restored from memory to the HASH registers.

The procedures where the data flow is controlled by software or by DMA are described hereafter.

**Data loaded by software**

When the DMA is not used to load the message into the hash processor, the context can be saved only when no block processing is ongoing.

**To suspend the processing of a message**, proceed as follows after writing 16 words 32-bit (plus one if it is the first block):

1. In Polling mode, wait for `BUSY = 0`, then poll if the `DINIS` status bit is set to 1.  
In Interrupt mode, implement the next step in `DINIS` interrupt handler (recommended).
2. Store the contents of the following registers into memory:
  - `HASH_IMR`
  - `HASH_STR`
  - `HASH_CR`
  - `HASH_CSR0` to `HASH_CSR37`. `HASH_CSR38` to `HASH_CSR53` registers must also be saved if an HMAC operation was ongoing.

**To resume the processing of a message**, proceed as follows:

1. Write the following registers with the values saved in memory: `HASH_IMR`, `HASH_STR` and `HASH_CR`.
2. Initialize the hash processor by setting the `INIT` bit in the `HASH_CR` register.
3. Write the `HASH_CSRx` registers with the values saved in memory.
4. Restart the processing from the point where it has been interrupted.

*Note:* To optimize the resume process when `NBW[3:0] = 0x0`, `HASH_CSR22` to `HASH_CSR37` registers do not need to be saved then restored as the `FIFO` is empty.

**Data loaded by DMA**

When the DMA is used to load the message into the hash processor, it is recommended to suspend and then restore a secure digest computing is described below.

**To suspend the processing of a message using DMA**, proceed as follows:

1. In Polling mode, wait for `BUSY = 0`. If `DCIS` is set in `HASH_SR`, the hash result is available and the context swapping is useless. Else go to step 2.
2. In Polling mode, wait for `BUSY = 1`.
3. Disable the DMA channel. Then clear `DMAE` bit in `HASH_CR` register.
4. In Polling mode, wait for `BUSY = 0`. If `DCIS` is set in `HASH_SR`, the hash result is available and the context swapping is useless. Else go to step 5.
5. Save `HASH_IMR`, `HASH_STR`, `HASH_CR`, and `HASH_CSR0` to `HASH_CSR37` registers. `HASH_CSR38` to `HASH_CSR53` registers must also be saved if an HMAC operation was ongoing.

**To resume the processing of a message using DMA**, proceed as follows:

1. Reconfigure the DMA controller so that it proceeds with the transfer of the message up to the end if it is not interrupted again. Do not forget to take into account the words that have been already pushed into the FIFO if NBW[3:0] is higher than 0x0.
2. Program the values saved in memory to HASH\_IMR, HASH\_STR and HASH\_CR registers.
3. Initialize the hash processor by setting the INIT bit in the HASH\_CR register.
4. Program the values saved in memory to the HASH\_CSRx registers.
5. Restart the processing from the point where it was interrupted by setting the DMAE bit.

*Note:* To optimize the resume process when NBW[3:0] = 0x0, HASH\_CSR22 to HASH\_CSR37 registers do not need to be saved then restored as the FIFO is empty.

### 29.4.9 HASH DMA interface

The HASH only supports single DMA transfers.

The hash processor provides an interface to connect to the DMA controller. This DMA can be used to write data to the HASH by setting the DMAE bit in the HASH\_CR register. When this bit is set, the HASH initiates a DMA request each time a block has to be written to the HASH\_DIN register.

Once four 32-bit words have been received, the HASH automatically triggers a new request to the DMA. For more information refer to [Section 29.4.5: Message digest computing](#).

Before starting the DMA transfer, the software must program the number of valid bits in the last word that is copied into HASH\_DIN register. This is done by writing in HASH\_STR register the following value:

**NBLW[4:0] = Len(Message) % 32** where “x%32” gives the remainder of x divided by 32.

The DMAS bit of the HASH\_SR register provides information on the DMA interface activity. This bit is set with DMAE and cleared when DMAE is cleared and no DMA transfer is ongoing.

*Note:* No interrupt is associated to DMAS bit.

When MDMAT is set, the size of the transfer must be a multiple of four words.

### 29.4.10 HASH error management

No error flags are generated by the hash processor.

## 29.5 HASH interrupts

Two individual maskable interrupt sources are generated by the hash processor to signal the following events:

- Digest calculation completion (DCIS)
- Data input buffer ready (DINIS)

Both interrupt sources are connected to the same global interrupt request signal (hash\_it), which is in turn connected to the NVIC (nested vectored interrupt controller). Each interrupt source can individually be enabled or disabled by changing the mask bits in the HASH\_IMR register. Setting the appropriate mask bit to 1 enables the interrupt.

The status of each maskable interrupt source can be read from the HASH\_SR register.  
[Table 193](#) gives a summary of the available features.

**Table 193. HASH interrupt requests**

| Interrupt acronym | Interrupt event                            | Event flag | Enable control bit | Interrupt clear method           |
|-------------------|--------------------------------------------|------------|--------------------|----------------------------------|
| HASH              | Digest computation completed               | DCIS       | DCIE               | Clear DCIS or set INIT           |
|                   | Data input buffer ready to get a new block | DINIS      | DINIE              | Clear DINIS or write to HASH_DIN |

## 29.6 HASH processing time

[Table 194](#) summarizes the time required to process an intermediate block for each mode of operation.

**Table 194. Processing time (in clock cycle)**

| Mode of operation | FIFO load <sup>(1)</sup> | Computation phase | Total     |
|-------------------|--------------------------|-------------------|-----------|
| MD5               | 16                       | 50                | <b>66</b> |
| SHA-1             | 16                       | 66                | <b>82</b> |
| SHA2-224          | 16                       | 50                | <b>66</b> |
| SHA2-256          |                          |                   |           |

1. Add the time required to load the block into the processor.

The time required to process the last block of a message (or of a key in HMAC) can be longer. This time depends on the length of the last block and the size of the key (in HMAC mode).

Compared to the processing of an intermediate block, it can be increased by the factor below:

- **1 to 2.5** for a hash message
- **~2.5** for an HMAC input-key
- **1 to 2.5** for an HMAC message
- **~2.5** for an HMAC output key in case of a short key
- **3.5 to 5** for an HMAC output key in case of a long key

## 29.7 HASH registers

The HASH core is associated with several control and status registers and several message digest registers. All these registers are accessible through 32-bit word accesses only, else an AHB error is generated.

### 29.7.1 HASH control register (HASH\_CR)

Address offset: 0x00

Reset value: 0x0000 0000

| 31   | 30   | 29    | 28    | 27       | 26   | 25   | 24   | 23    | 22   | 21            | 20   | 19   | 18    | 17   | 16   |
|------|------|-------|-------|----------|------|------|------|-------|------|---------------|------|------|-------|------|------|
| Res. | Res. | Res.  | Res.  | Res.     | Res. | Res. | Res. | Res.  | Res. | Res.          | Res. | Res. | ALGO1 | Res. | LKEY |
|      |      |       |       |          |      |      |      |       |      |               |      |      | rw    |      | rw   |
| 15   | 14   | 13    | 12    | 11       | 10   | 9    | 8    | 7     | 6    | 5             | 4    | 3    | 2     | 1    | 0    |
| Res. | Res. | MDMAT | DINNE | NBW[3:0] |      |      |      | ALGO0 | MODE | DATATYPE[1:0] |      | DMAE | INIT  | Res. | Res. |
|      |      | rw    | r     | r        | r    | r    | r    | rw    | rw   | rw            | rw   | rw   | rw    |      |      |

Bits 31:19 Reserved, must be kept at reset value.

Bit 17 Reserved, must be kept at reset value.

Bit 16 **LKEY**: Long key selection

This bit selects between short key ( $\leq 64$  bytes) or long key ( $> 64$  bytes) in HMAC mode.

0: the HMAC key is shorter or equal to 64 bytes. The actual key value written to HASH\_DIN is used during the HMAC computation.

1: the HMAC key is longer than 64 bytes. The hash of the key is used instead of the real key during the HMAC computation.

This selection is only taken into account when the INIT and MODE bits are both set.

Changing this bit during a computation has no effect.

Bit 15 Reserved, must be kept at reset value.

Bit 14 Reserved, must be kept at reset value.

Bit 13 **MDMAT**: Multiple DMA transfers

This bit is set when hashing large files when multiple DMA transfers are needed.

0: DCAL is automatically set at the end of a DMA transfer.

1: DCAL is not automatically set at the end of a DMA transfer.

Bit 12 **DINNE**: DIN not empty

This bit is set when the HASH\_DIN register holds valid data (that is after being written at least once). It is cleared when either the INIT bit (initialization) or the DCAL bit (completion of the previous message processing) is written to 1.

0: No data are present in the data input buffer

1: The input buffer contains at least one word of data

This bit is read-only.

Bits 11:8 **NBW[3:0]**: Number of words already pushed

This bitfield reflects the number of words in the message that have already been pushed into the IN FIFO. NBW is incremented by one when a write access to the HASH\_DIN register is performed (except if DINNE = 0 and the DMA is not used, see below description). NBW goes to zero when the INIT bit is written to 1.

This bitfield is read-only.

**If the DMA is not used**

0000: if DINNE = 0, no word has been pushed into the DIN buffer (both HASH\_DIN register and IN FIFO are empty), otherwise one word has been pushed into the DIN buffer (HASH\_DIN register contains one word and IN FIFO is empty)

0001: two words have been pushed into the DIN buffer (that is HASH\_DIN register and the IN FIFO contain one word each)

...

1111: 16 words have been pushed into the DIN buffer.

**If the DMA is used**

NBW contains the exact number of words that have been pushed into the IN FIFO by the DMA.

Bits 18, 7 **ALGO[1:0]**: Algorithm selection

These bits select the hash algorithm.

00: SHA-1

01: MD5

10: SHA2-224

11: SHA2-256

This selection is only taken into account when the INIT bit is set. Changing this bitfield during a computation has no effect.

Bit 6 **MODE**: Mode selection

This bit selects the HASH or HMAC mode for the selected algorithm:

0: Hash mode selected

1: HMAC mode selected. LKEY must be set if the key being used is longer than 64 bytes.

This selection is only taken into account when the INIT bit is set. Changing this bit during a computation has no effect.

Bits 5:4 **DATATYPE[1:0]**: Data type selection

Defines the format of the data entered into the HASH\_DIN register:

00: 32-bit data. The data written into HASH\_DIN are directly used by the HASH processing, without reordering.

01: 16-bit data, or half-word. The data written into HASH\_DIN are considered as two half-words, and are swapped before being used by the HASH processing.

10: 8-bit data, or bytes. The data written into HASH\_DIN are considered as four bytes, and are swapped before being used by the HASH processing.

11: bit data, or bit-string. The data written into HASH\_DIN are considered as 32 bits (1st bit of the string at position 0), and are swapped before being used by the HASH processing (1st bit of the string at position 31).

Bit 3 **DMAE**: DMA enable

0: DMA transfers disabled

1: DMA transfers enabled. A DMA request is sent as soon as the HASH core is ready to receive data.

After this bit is set it is cleared by hardware while the last data of the message is written into the hash processor.

Setting this bit to 0 while a DMA transfer is ongoing is not aborting this current transfer.

Instead, the DMA interface of the IP remains internally enabled until the transfer is completed or INIT is written to 1.

Setting INIT bit to 1 does not clear DMAE bit.

Bit 2 **INIT**: Initialize message digest calculation

Writing this bit to 1 resets the hash processor core, so that the HASH is ready to compute the message digest of a new message.

Writing this bit to 0 has no effect. Reading this bit always return 0.

Bits 1:0 Reserved, must be kept at reset value.

## 29.7.2 HASH data input register (HASH\_DIN)

Address offset: 0x04

Reset value: 0x0000 0000

HASH\_DIN is the data input register. It is 32-bit wide. This register is used to enter the message by blocks. When the HASH\_DIN register is programmed, the value presented on the AHB databus is 'pushed' into the hash core and the register takes the new value presented on the AHB databus. To get a correct message format, the DATATYPE bits must have been previously configured in the HASH\_CR register.

When a complete block has been written to the HASH\_DIN register, an intermediate digest calculation is launched:

- by writing new data into the HASH\_DIN register (the first word of the next block) if the DMA is not used (intermediate digest calculation),
- automatically if the DMA is used.

When the last block has been written to the HASH\_DIN register, the final digest calculation (including padding) is launched by writing the DCAL bit to 1 in the HASH\_STR register (final digest calculation). This operation is automatic if the DMA is used and MDMAT bit is set to 0.

Reading the HASH\_DIN register returns the last word written to this location (zero after reset).

**Note:** When the HASH is busy, a write access to the HASH\_DIN register might stall the AHB bus if the digest calculation (intermediate or final) is not complete.

|               |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|---------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31            | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| DATAIN[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw            | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
| 15            | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| DATAIN[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw            | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:0 **DATAIN[31:0]**: Data input

Writing this register pushes the current register content into the IN FIFO, and the register takes the new value presented on the AHB databus.

Reading this register returns the current register content.

### 29.7.3 HASH start register (HASH\_STR)

Address offset: 0x08

Reset value: 0x0000 0000

The HASH\_STR register has two functions:

- It is used to define the number of valid bits in the last word of the message entered in the hash processor (that is the number of valid least significant bits in the last data written to the HASH\_DIN register).
- It is used to start the processing of the last block in the message by writing the DCAL bit to 1.

|      |      |      |      |      |      |      |      |      |      |      |           |      |      |      |      |
|------|------|------|------|------|------|------|------|------|------|------|-----------|------|------|------|------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20        | 19   | 18   | 17   | 16   |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.      | Res. | Res. | Res. | Res. |
|      |      |      |      |      |      |      |      |      |      |      |           |      |      |      |      |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4         | 3    | 2    | 1    | 0    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | DCAL | Res. | Res. | Res. | NBLW[4:0] |      |      |      |      |
|      |      |      |      |      |      |      | rw   |      |      |      | rw        | rw   | rw   | rw   | rw   |

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **DCAL**: Digest calculation

Writing this bit to 1 starts the message padding, using the previously written value of NBLW[4:0], and starts the calculation of the final message digest with all data words written to the input FIFO since the INIT bit was last written to 1.

Reading this bit returns 0.

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **NBLW[4:0]**: Number of valid bits in the last word

When the last word of the message bit string is written in HASH\_DIN register, the hash processor takes only the valid bits specified as below, after internal data swapping:

0x00: All 32 bits of the last data written are valid message bits that is M[31:0]

0x01: Only one bit of the last data written (after swapping) is valid that is M[0]

0x02: Only two bits of the last data written (after swapping) are valid that is M[1:0]

0x03: Only three bits of the last data written (after swapping) are valid that is M[2:0]

...

0x1F: Only 31 bits of the last data written (after swapping) are valid that is M[30:0]

The above mechanism is valid only if DCAL = 0. If NBLW[4:0] bitfield is written while DCAL is set to 1, the NBLW[4:0] bitfield remains unchanged. In other words it is not possible to configure NBLW[4:0] and set DCAL at the same time.

Reading NBLW[4:0] bitfield returns the last value written to NBLW[4:0].

## 29.7.4 HASH digest registers

These registers contain the message digest result named as follows:

- HASH\_HR0, HASH\_HR1, HASH\_HR2, HASH\_HR3 and HASH\_HR4 registers return the SHA-1 digest result
- HASH\_HR0, HASH\_HR1, HASH\_HR2 and HASH\_HR3 registers return A, B, C and D (respectively), as defined by MD5.
- HASH\_HR0 to HASH\_HR6 registers return the SHA2-224 digest result.
- HASH\_HR0 to HASH\_HR7 registers return the SHA2-256 digest result.

In all cases, the digest most significant bit is stored in HASH\_H0[31] and unused HASH\_HRx registers are read as zeros.

If a read access to one of these registers is performed while the hash core is calculating an intermediate digest or a final message digest (DCIS bit equals 0), then the read operation is stalled until the hash calculation has completed.

*Note:* When starting a digest computation for a new message (by writing the INIT bit to 1), HASH\_HRx registers are forced to their reset values.  
HASH\_HR0 to HASH\_HR4 registers can be accessed through two different addresses.

### HASH aliased digest register x (HASH\_HRAx)

Address offset:  $0x0C + 0x4 * x$ , ( $x = 0$  to  $4$ )

Reset value: 0x0000 0000

The content of the HASH\_HRAx registers is identical to the one of the HASH\_HRx registers located at address offset 0x310.

|           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31        | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Hx[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| r         | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  |

|      |      |      |      |      |      |      |      |      |      |      |      | r    | r    | rc_w0 | rc_w0 |

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **BUSY**: Busy bit

- 0: No block is currently being processed
- 1: The hash core is processing a block of data

Bit 2 **DMAS**: DMA Status

- This bit provides information on the DMA interface activity. It is set with DMAE and cleared when DMAE = 0 and no DMA transfer is ongoing. No interrupt is associated with this bit.
- 0: DMA interface is disabled (DMAE = 0) and no transfer is ongoing
  - 1: DMA interface is enabled (DMAE = 1) or a transfer is ongoing

Bit 1 **DCIS**: Digest calculation completion interrupt status

- This bit is set by hardware when a digest becomes ready (the whole message has been processed). It is cleared by writing it to 0 or by writing the INIT bit to 1 in the HASH\_CR register.
- 0: No digest available in the HASH\_HRx registers (zeros are returned)
  - 1: Digest calculation complete, a digest is available in the HASH\_HRx registers. An interrupt is generated if the DCIE bit is set in the HASH\_IMR register.

Bit 0 **DINIS**: Data input interrupt status

- This bit is set by hardware when the FIFO is ready to get a new block (16 locations are free). It is cleared by writing it to 0 or by writing the HASH\_DIN register.
- 0: Less than 16 locations are free in the input buffer
  - 1: A new block can be entered into the input buffer. An interrupt is generated if the DINIE bit is set in the HASH\_IMR register.
- When DINIS=0, HASH\_CSRx registers reads as zero.

## 29.7.7 HASH context swap registers

These registers contain the complete internal register states of the hash processor. They are useful when a suspend/resume operation has to be performed because a high-priority task needs to use the hash processor while it is already used by another task.

When such an event occurs, the HASH\_CSRx registers have to be read and the read values have to be saved in the system memory space. Then the hash processor can be used by the preemptive task, and when the hash computation is complete, the saved context can be read from memory and written back into the HASH\_CSRx registers.

HASH\_CSRx registers can be read only when DINIS equals to 1, otherwise zeros are returned.

**HASH context swap register x (HASH\_CSRx)**Address offset:  $0x0F8 + x * 0x4$ , ( $x = 0$  to  $53$ )Reset value:  $0x0000\ 0002$  (HASH\_CSR0)Reset value:  $0x0000\ 0000$  (HASH\_CSR1 to  $53$ )

## 30 Advanced-control timers (TIM1/TIM8)

### 30.1 TIM1/TIM8 introduction

The advanced-control timers (TIM1/TIM8) consist of a 16-bit auto-reload counter driven by a programmable prescaler.

It may be used for a variety of purposes, including measuring the pulse lengths of input signals (input capture) or generating output waveforms (output compare, PWM, complementary PWM with dead-time insertion).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The advanced-control (TIM1/TIM8) and general-purpose (TIMy) timers are completely independent, and do not share any resources. They can be synchronized together as described in [Section 30.3.26: Timer synchronization](#).

### 30.2 TIM1/TIM8 main features

TIM1/TIM8 timer features include:

- 16-bit up, down, up/down auto-reload counter.
- 16-bit programmable prescaler allowing dividing (also “on the fly”) the counter clock frequency either by any factor between 1 and 65536.
- Up to 6 independent channels for:
  - Input Capture (but channels 5 and 6)
  - Output Compare
  - PWM generation (Edge and Center-aligned Mode)
  - One-pulse mode output
- Complementary outputs with programmable dead-time
- Synchronization circuit to control the timer with external signals and to interconnect several timers together.
- Repetition counter to update the timer registers only after a given number of cycles of the counter.
- 2 break inputs to put the timer’s output signals in a safe user selectable configuration.
- Interrupt/DMA generation on the following events:
  - Update: counter overflow/underflow, counter initialization (by software or internal/external trigger)
  - Trigger event (counter start, stop, initialization or count by internal/external trigger)
  - Input capture
  - Output compare
- Supports incremental (quadrature) encoder and Hall-sensor circuitry for positioning purposes
- Trigger input for external clock or cycle-by-cycle current management

## 30.3 TIM1/TIM8 functional description

### 30.3.1 Time-base unit

The main block of the programmable advanced-control timer is a 16-bit counter with its related auto-reload register. The counter can count up, down or both up and down. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:

- Counter register (TIMx\_CNT)
- Prescaler register (TIMx\_PSC)
- Auto-reload register (TIMx\_ARR)
- Repetition counter register (TIMx\_RCR)

The auto-reload register is preloaded. Writing to or reading from the auto-reload register accesses the preload register. The content of the preload register are transferred into the shadow register permanently or at each update event (UEV), depending on the auto-reload preload enable bit (ARPE) in TIMx\_CR1 register. The update event is sent when the counter reaches the overflow (or underflow when downcounting) and if the UDIS bit equals 0 in the TIMx\_CR1 register. It can also be generated by software. The generation of the update event is described in detailed for each configuration.

The counter is clocked by the prescaler output CK\_CNT, which is enabled only when the counter enable bit (CEN) in TIMx\_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

Note that the counter starts counting 1 clock cycle after setting the CEN bit in the TIMx\_CR1 register.

#### Prescaler description

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx\_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

*Figure 224* and *Figure 225* give some examples of the counter behavior when the prescaler ratio is changed on the fly:

Figure 224. Counter timing diagram with prescaler division change from 1 to 2

Figure 225. Counter timing diagram with prescaler division change from 1 to 4

### 30.3.2 Counter modes

#### Upcounting mode

In upcounting mode, the counter counts from 0 to the auto-reload value (content of the TIMx\_ARR register), then restarts from 0 and generates a counter overflow event.

If the repetition counter is used, the update event (UEV) is generated after upcounting is repeated for the number of times programmed in the repetition counter register (TIMx\_RCR) + 1. Else the update event is generated at each counter overflow.

Setting the UG bit in the TIMx\_EGR register (by software or by using the slave mode controller) also generates an update event.

The UEV event can be disabled by software by setting the UDIS bit in the TIMx\_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIMx\_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx\_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx\_RCR register,
- The auto-reload shadow register is updated with the preload value (TIMx\_ARR),
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx\_PSC register).

The following figures show some examples of the counter behavior for different clock frequencies when TIMx\_ARR=0x36.

Figure 230. Counter timing diagram, update event when ARPE=0 (TIMx\_ARR not preloaded)

Figure 231. Counter timing diagram, update event when ARPE=1 (TIMx\_ARR preloaded)

### Downcounting mode

In downcounting mode, the counter counts from the auto-reload value (content of the TIMx\_ARR register) down to 0, then restarts from the auto-reload value and generates a counter underflow event.

If the repetition counter is used, the update event (UEV) is generated after downcounting is repeated for the number of times programmed in the repetition counter register (TIMx\_RCR) + 1. Else the update event is generated at each counter underflow.

Setting the UG bit in the TIMx\_EGR register (by software or by using the slave mode controller) also generates an update event.

The UEV update event can be disabled by software by setting the UDIS bit in TIMx\_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until UDIS bit has been written to 0. However, the counter restarts from the current auto-reload value, whereas the counter of the prescaler restarts from 0 (but the prescale rate doesn't change).

In addition, if the URS bit (update request selection) in TIMx\_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx\_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx\_RCR register.
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx\_PSC register).
- The auto-reload active register is updated with the preload value (content of the TIMx\_ARR register). Note that the auto-reload is updated before the counter is reloaded, so that the next period is the expected one.

The following figures show some examples of the counter behavior for different clock frequencies when TIMx\_ARR=0x36.

Figure 232. Counter timing diagram, internal clock divided by 1

Figure 233. Counter timing diagram, internal clock divided by 2

Figure 234. Counter timing diagram, internal clock divided by 4

Figure 235. Counter timing diagram, internal clock divided by N

**Figure 236. Counter timing diagram, update event when repetition counter is not used**

### Center-aligned mode (up/down counting)

In center-aligned mode, the counter counts from 0 to the auto-reload value (content of the TIMx\_ARR register) – 1, generates a counter overflow event, then counts from the auto-reload value down to 1 and generates a counter underflow event. Then it restarts counting from 0.

Center-aligned mode is active when the CMS bits in TIMx\_CR1 register are not equal to '00'. The Output compare interrupt flag of channels configured in output is set when: the counter counts down (Center aligned mode 1, CMS = "01"), the counter counts up (Center aligned mode 2, CMS = "10") the counter counts up and down (Center aligned mode 3, CMS = "11").

In this mode, the DIR direction bit in the TIMx\_CR1 register cannot be written. It is updated by hardware and gives the current direction of the counter.

The update event can be generated at each counter overflow and at each counter underflow or by setting the UG bit in the TIMx\_EGR register (by software or by using the slave mode controller) also generates an update event. In this case, the counter restarts counting from 0, as well as the counter of the prescaler.

The UEV update event can be disabled by software by setting the UDIS bit in the TIMx\_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until UDIS bit has been written to 0. However, the counter continues counting up and down, based on the current auto-reload value.

In addition, if the URS bit (update request selection) in TIMx\_CR1 register is set, setting the UG bit generates an UEV update event but without setting the UIF flag (thus no interrupt or

DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx\_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx\_RCR register
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx\_PSC register)
- The auto-reload active register is updated with the preload value (content of the TIMx\_ARR register). Note that if the update source is a counter overflow, the auto-reload is updated before the counter is reloaded, so that the next period is the expected one (the counter is loaded with the new value).

The following figures show some examples of the counter behavior for different clock frequencies.

**Figure 237. Counter timing diagram, internal clock divided by 1, TIMx\_ARR = 0x6**

1. Here, center-aligned mode 1 is used (for more details refer to [Section 30.4: TIM1/TIM8 registers](#)).

Figure 240. Counter timing diagram, internal clock divided by N

Figure 241. Counter timing diagram, update event with ARPE=1 (counter underflow)

**Figure 242. Counter timing diagram, Update event with ARPE=1 (counter overflow)**

### 30.3.3 Repetition counter

[Section 30.3.1: Time-base unit](#) describes how the update event (UEV) is generated with respect to the counter overflows/underflows. It is actually generated only when the repetition counter has reached zero. This can be useful when generating PWM signals.

This means that data are transferred from the preload registers to the shadow registers (TIMx\_ARR auto-reload register, TIMx\_PSC prescaler register, but also TIMx\_CCRx capture/compare registers in compare mode) every N+1 counter overflows or underflows, where N is the value in the TIMx\_RCR repetition counter register.

The repetition counter is decremented:

- At each counter overflow in upcounting mode,
  - At each counter underflow in downcounting mode,
  - At each counter overflow and at each counter underflow in center-aligned mode.
- Although this limits the maximum number of repetition to 32768 PWM cycles, it makes it possible to update the duty cycle twice per PWM period. When refreshing compare registers only once per PWM period in center-aligned mode, maximum resolution is  $2 \times T_{ck}$ , due to the symmetry of the pattern.

The repetition counter is an auto-reload type; the repetition rate is maintained as defined by the TIMx\_RCR register value (refer to [Figure 243](#)). When the update event is generated by software (by setting the UG bit in TIMx\_EGR register) or by hardware through the slave mode controller, it occurs immediately whatever the value of the repetition counter is and the repetition counter is reloaded with the content of the TIMx\_RCR register.

In Center aligned mode, for odd values of RCR, the update event occurs either on the overflow or on the underflow depending on when the RCR register was written and when the counter was launched: if the RCR was written before launching the counter, the UEV occurs on the underflow. If the RCR was written after launching the counter, the UEV occurs on the overflow.

For example, for RCR = 3, the UEV is generated each 4th overflow or underflow event depending on when the RCR was written.

**Figure 243. Update rate examples depending on mode and TIMx\_RCR register settings**

### 30.3.4 External trigger input

The timer features an external trigger input ETR. It can be used as:

- external clock (external clock mode 2, see [Section 30.3.5](#))
- trigger for the slave mode (see [Section 30.3.26](#))
- PWM reset input for cycle-by-cycle current regulation (see [Section 30.3.7](#))

[Figure 244](#) below describes the ETR input conditioning. The input polarity is defined with the ETP bit in TIMxSMCR register. The trigger can be prescaled with the divider programmed by the ETPS[1:0] bitfield and digitally filtered with the ETF[3:0] bitfield.

**Figure 244. External trigger input block**

The ETR input comes from multiple sources: input pins (default configuration), comparator outputs and analog watchdogs. The selection is done with:

- the ETRSEL[2:0] bitfield in the TIMx\_OR2 register
- the ETR\_ADC1\_RMP bitfield in the TIMxOR1[1:0] register
- the ETR\_ADC3\_RMP bitfield in the TIMxOR1[3:2] register.

**Figure 245. TIM1 ETR input circuitry**

Figure 246. TIM8 ETR input circuitry

### 30.3.5 Clock selection

The counter clock can be provided by the following clock sources:

- Internal clock (CK\_INT)
- External clock mode1: external input pin
- External clock mode2: external trigger input ETR
- Encoder mode

#### Internal clock source (CK\_INT)

If the slave mode controller is disabled (SMS=000), then the CEN, DIR (in the TIMx\_CR1 register) and UG bits (in the TIMx\_EGR register) are actual control bits and can be changed only by software (except UG which remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock CK\_INT.

*Figure 247* shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.

**Figure 247. Control circuit in normal mode, internal clock divided by 1**

#### External clock source mode 1

This mode is selected when SMS=111 in the TIMx\_SMCR register. The counter can count at each rising or falling edge on a selected input.

Figure 248. TI2 external clock connection example

MS31196V1

For example, to configure the upcounter to count in response to a rising edge on the TI2 input, use the following procedure:

1. Configure channel 2 to detect rising edges on the TI2 input by writing CC2S = '01' in the TIMx\_CCMR1 register.
2. Configure the input filter duration by writing the IC2F[3:0] bits in the TIMx\_CCMR1 register (if no filter is needed, keep IC2F=0000).
3. Select rising edge polarity by writing CC2P=0 and CC2NP=0 in the TIMx\_CCER register.
4. Configure the timer in external clock mode 1 by writing SMS=111 in the TIMx\_SMCR register.
5. Select TI2 as the trigger input source by writing TS=110 in the TIMx\_SMCR register.
6. Enable the counter by writing CEN=1 in the TIMx\_CR1 register.

**Note:** The capture prescaler is not used for triggering, so the user does not need to configure it.

When a rising edge occurs on TI2, the counter counts once and the TIF flag is set.

The delay between the rising edge on TI2 and the actual clock of the counter is due to the resynchronization circuit on TI2 input.

Figure 249. Control circuit in external clock mode 1

### External clock source mode 2

This mode is selected by writing ECE=1 in the TIMx\_SMCR register.

The counter can count at each rising or falling edge on the external trigger input ETR.

The [Figure 250](#) gives an overview of the external trigger input block.

Figure 250. External trigger input block

For example, to configure the upcounter to count each 2 rising edges on ETR, use the following procedure:

1. As no filter is needed in this example, write ETRF[3:0]=0000 in the TIMx\_SMCR register.
2. Set the prescaler by writing ETPS[1:0]=01 in the TIMx\_SMCR register
3. Select rising edge detection on the ETR pin by writing ETP=0 in the TIMx\_SMCR register
4. Enable external clock mode 2 by writing ECE=1 in the TIMx\_SMCR register.
5. Enable the counter by writing CEN=1 in the TIMx\_CR1 register.

The counter counts once each 2 ETR rising edges.

The delay between the rising edge on ETR and the actual clock of the counter is due to the resynchronization circuit on the ETRP signal. As a consequence, the maximum frequency which can be correctly captured by the counter is at most  $\frac{1}{4}$  of TIMxCLK frequency. When the ETRP signal is faster, the user should apply a division of the external signal by proper ETPS prescaler setting.

**Figure 251. Control circuit in external clock mode 2**

### 30.3.6 Capture/compare channels

Each Capture/Compare channel is built around a capture/compare register (including a shadow register), an input stage for capture (with digital filter, multiplexing, and prescaler, except for channels 5 and 6) and an output stage (with comparator and output control).

[Figure 252](#) to [Figure 255](#) give an overview of one Capture/Compare channel.

The input stage samples the corresponding TIx input to generate a filtered signal TIxF. Then, an edge detector with polarity selection generates a signal (TIxFPx) which can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (ICxPS).

**Figure 252. Capture/compare channel (example: channel 1 input stage)**

The output stage generates an intermediate waveform which is then used for reference: OCxRef (active high). The polarity acts at the end of the chain.

Figure 253. Capture/compare channel 1 main circuit

Figure 254. Output stage of capture/compare channel (channel 1, idem ch. 2 and 3)

1. OCxREF, where x is the rank of the complementary channel

**Figure 255. Output stage of capture/compare channel (channel 4)****Figure 256. Output stage of capture/compare channel (channel 5, idem ch. 6)**

1. Not available externally.

The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register.

In capture mode, captures are actually done in the shadow register, which is copied into the preload register.

In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

### 30.3.7 Input capture mode

In Input capture mode, the Capture/Compare Registers (TIMx\_CCRx) are used to latch the value of the counter after a transition detected by the corresponding ICx signal. When a capture occurs, the corresponding CCxIF flag (TIMx\_SR register) is set and an interrupt or a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was already high, then the over-capture flag CCxOF (TIMx\_SR register) is set. CCxIF can be cleared by software by writing it to '0' or by reading the captured data stored in the TIMx\_CCRx register. CCxOF is cleared when written with '0'.

The following example shows how to capture the counter value in TIMx\_CCR1 when TI1 input rises. To do this, use the following procedure:

1. Select the active input: TIMx\_CCR1 must be linked to the TI1 input, so write the CC1S bits to 01 in the TIMx\_CCMR1 register. As soon as CC1S becomes different from 00, the channel is configured in input and the TIMx\_CCR1 register becomes read-only.
2. Program the appropriate input filter duration in relation with the signal connected to the timer (when the input is one of the TIx (ICxF bits in the TIMx\_CCMRx register). Let's imagine that, when toggling, the input signal is not stable during at most 5 internal clock cycles. We must program a filter duration longer than these 5 clock cycles. We can validate a transition on TI1 when 8 consecutive samples with the new level have been detected (sampled at  $f_{DTS}$  frequency). Then write IC1F bits to 0011 in the TIMx\_CCMR1 register.
3. Select the edge of the active transition on the TI1 channel by writing CC1P and CC1NP bits to 0 in the TIMx\_CCER register (rising edge in this case).
4. Program the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to '00' in the TIMx\_CCMR1 register).
5. Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx\_CCER register.
6. If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx\_DIER register, and/or the DMA request by setting the CC1DE bit in the TIMx\_DIER register.

When an input capture occurs:

- The TIMx\_CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.
- A DMA request is generated depending on the CC1DE bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which could happen after reading the flag and before reading the data.

*Note:* IC interrupt and/or DMA requests can be generated by software by setting the corresponding CCxG bit in the TIMx\_EGR register.

### 30.3.8 PWM input mode

This mode is a particular case of input capture mode. The procedure is the same except:

- Two ICx signals are mapped on the same TIx input.
- These 2 ICx signals are active on edges with opposite polarity.
- One of the two TIxFP signals is selected as trigger input and the slave mode controller is configured in reset mode.

For example, the user can measure the period (in TIMx\_CCR1 register) and the duty cycle (in TIMx\_CCR2 register) of the PWM applied on TI1 using the following procedure (depending on CK\_INT frequency and prescaler value):

1. Select the active input for TIMx\_CCR1: write the CC1S bits to 01 in the TIMx\_CCMR1 register (TI1 selected).
2. Select the active polarity for TI1FP1 (used both for capture in TIMx\_CCR1 and counter clear): write the CC1P and CC1NP bits to '0' (active on rising edge).
3. Select the active input for TIMx\_CCR2: write the CC2S bits to 10 in the TIMx\_CCMR1 register (TI1 selected).
4. Select the active polarity for TI1FP2 (used for capture in TIMx\_CCR2): write the CC2P and CC2NP bits to CC2P/CC2NP='10' (active on falling edge).
5. Select the valid trigger input: write the TS bits to 101 in the TIMx\_SMCR register (TI1FP1 selected).
6. Configure the slave mode controller in reset mode: write the SMS bits to 0100 in the TIMx\_SMCR register.
7. Enable the captures: write the CC1E and CC2E bits to '1' in the TIMx\_CCER register.

**Figure 257. PWM input mode timing**

### 30.3.9 Forced output mode

In output mode (CCxS bits = 00 in the TIMx\_CCMRx register), each output compare signal (OCxREF and then OCx/OCxN) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (OCXREF/OCx) to its active level, user just needs to write 0101 in the OCxM bits in the corresponding TIMx\_CCMRx register. Thus OCXREF is

forced high (OCxREF is always active high) and OCx get opposite value to CCxP polarity bit.

For example: CCxP=0 (OCx active high) => OCx is forced to high level.

The OCxREF signal can be forced low by writing the OCxM bits to 0100 in the TIMx\_CCMRx register.

Anyway, the comparison between the TIMx\_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt and DMA requests can be sent accordingly. This is described in the output compare mode section below.

### 30.3.10 Output compare mode

This function is used to control an output waveform or indicate when a period of time has elapsed. Channels 1 to 4 can be output, while Channel 5 and 6 are only available inside the device (for instance, for compound waveform generation or for ADC triggering).

When a match is found between the capture/compare register and the counter, the output compare function:

- Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx\_CCMRx register) and the output polarity (CCxP bit in the TIMx\_CCER register). The output pin can keep its level (OCxM=0000), be set active (OCxM=0001), be set inactive (OCxM=0010) or can toggle (OCxM=0011) on match.
- Sets a flag in the interrupt status register (CCxIF bit in the TIMx\_SR register).
- Generates an interrupt if the corresponding interrupt mask is set (CCXIE bit in the TIMx\_DIER register).
- Sends a DMA request if the corresponding enable bit is set (CCxDE bit in the TIMx\_DIER register, CCDS bit in the TIMx\_CR2 register for the DMA request selection).

The TIMx\_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx\_CCMRx register.

In output compare mode, the update event UEV has no effect on OCxREF and OCx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One Pulse mode).

#### Procedure

1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx\_ARR and TIMx\_CCRx registers.
3. Set the CCxIE bit if an interrupt request is to be generated.
4. Select the output mode. For example:
  - Write OCxM = 0011 to toggle OCx output pin when CNT matches CCRx
  - Write OCxPE = 0 to disable preload register
  - Write CCxP = 0 to select active high polarity
  - Write CCxE = 1 to enable the output
5. Enable the counter by setting the CEN bit in the TIMx\_CR1 register.

The TIMx\_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE='0', else TIMx\_CCRx

shadow register is updated only at the next update event UEV). An example is given in [Figure 258](#).

**Figure 258. Output compare mode, toggle on OC1**

### 30.3.11 PWM mode

Pulse Width Modulation mode allows a signal to be generated with a frequency determined by the value of the TIMx\_ARR register and a duty cycle determined by the value of the TIMx\_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per OCx output) by writing '0110' (PWM mode 1) or '0111' (PWM mode 2) in the OCxM bits in the TIMx\_CCMRx register. The corresponding preload register must be enabled by setting the OCxPE bit in the TIMx\_CCMRx register, and eventually the auto-reload preload register (in upcounting or center-aligned modes) by setting the ARPE bit in the TIMx\_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, all registers must be initialized by setting the UG bit in the TIMx\_EGR register.

OCx polarity is software programmable using the CCxP bit in the TIMx\_CCER register. It can be programmed as active high or active low. OCx output is enabled by a combination of the CCxE, CCxNE, MOE, OSSI and OSSR bits (TIMx\_CCER and TIMx\_BDTR registers). Refer to the TIMx\_CCER register description for more details.

In PWM mode (1 or 2), TIMx\_CNT and TIMx\_CCRx are always compared to determine whether  $\text{TIMx\_CCRx} \leq \text{TIMx\_CNT}$  or  $\text{TIMx\_CNT} \leq \text{TIMx\_CCRx}$  (depending on the direction of the counter).

The timer is able to generate PWM in edge-aligned mode or center-aligned mode depending on the CMS bits in the TIMx\_CR1 register.

### PWM edge-aligned mode

- Upcounting configuration

Upcounting is active when the DIR bit in the TIMx\_CR1 register is low. Refer to the [Upcounting mode on page 900](#).

In the following example, we consider PWM mode 1. The reference PWM signal OCxREF is high as long as TIMx\_CNT < TIMx\_CCRx else it becomes low. If the compare value in TIMx\_CCRx is greater than the auto-reload value (in TIMx\_ARR) then OCxREF is held at '1'. If the compare value is 0 then OCxRef is held at '0'.

[Figure 259](#) shows some edge-aligned PWM waveforms in an example where TIMx\_ARR=8.

**Figure 259. Edge-aligned PWM waveforms (ARR=8)**

- Downcounting configuration

Downcounting is active when DIR bit in TIMx\_CR1 register is high. Refer to the [Downcounting mode on page 904](#)

In PWM mode 1, the reference signal OCxRef is low as long as TIMx\_CNT > TIMx\_CCRx else it becomes high. If the compare value in TIMx\_CCRx is greater than the auto-reload value in TIMx\_ARR, then OCxREF is held at '1'. 0% PWM is not possible in this mode.

### PWM center-aligned mode

Center-aligned mode is active when the CMS bits in TIMx\_CR1 register are different from '00' (all the remaining configurations having the same effect on the OCxRef/OCx signals). The compare flag is set when the counter counts up, when it counts down or both when it counts up and down depending on the CMS bits configuration. The direction bit (DIR) in the

TIMx\_CR1 register is updated by hardware and must not be changed by software. Refer to the [Center-aligned mode \(up/down counting\) on page 907](#).

Figure 260 shows some center-aligned PWM waveforms in an example where:

- TIMx\_ARR=8,
- PWM mode is the PWM mode 1,
- The flag is set when the counter counts down corresponding to the center-aligned mode 1 selected for CMS=01 in TIMx\_CR1 register.

**Figure 260. Center-aligned PWM waveforms (ARR=8)**

Hints on using center-aligned mode

- When starting in center-aligned mode, the current up-down configuration is used. It means that the counter counts up or down depending on the value written in the DIR bit

in the TIMx\_CR1 register. Moreover, the DIR and CMS bits must not be changed at the same time by the software.

- Writing to the counter while running in center-aligned mode is not recommended as it can lead to unexpected results. In particular:
  - The direction is not updated if a value greater than the auto-reload value is written in the counter (TIMx\_CNT > TIMx\_ARR). For example, if the counter was counting up, it continues to count up.
  - The direction is updated if 0 or the TIMx\_ARR value is written in the counter but no Update Event UEV is generated.
- The safest way to use center-aligned mode is to generate an update by software (setting the UG bit in the TIMx\_EGR register) just before starting the counter and not to write the counter while it is running.

### 30.3.12 Asymmetric PWM mode

Asymmetric mode allows two center-aligned PWM signals to be generated with a programmable phase shift. While the frequency is determined by the value of the TIMx\_ARR register, the duty cycle and the phase-shift are determined by a pair of TIMx\_CCRx register. One register controls the PWM during up-counting, the second during down counting, so that PWM is adjusted every half PWM cycle:

- OC1REFC (or OC2REFC) is controlled by TIMx\_CCR1 and TIMx\_CCR2
- OC3REFC (or OC4REFC) is controlled by TIMx\_CCR3 and TIMx\_CCR4

Asymmetric PWM mode can be selected independently on two channel (one OCx output per pair of CCR registers) by writing '1110' (Asymmetric PWM mode 1) or '1111' (Asymmetric PWM mode 2) in the OCxM bits in the TIMx\_CCMRx register.

*Note: The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.*

When a given channel is used as asymmetric PWM channel, its complementary channel can also be used. For instance, if an OC1REFC signal is generated on channel 1 (Asymmetric PWM mode 1), it is possible to output either the OC2REF signal on channel 2, or an OC2REFC signal resulting from asymmetric PWM mode 1.

[Figure 261](#) represents an example of signals that can be generated using Asymmetric PWM mode (channels 1 to 4 are configured in Asymmetric PWM mode 1). Together with the deadtime generator, this allows a full-bridge phase-shifted DC to DC converter to be controlled.

**Figure 261. Generation of 2 phase-shifted PWM signals with 50% duty cycle**

### 30.3.13 Combined PWM mode

Combined PWM mode allows two edge or center-aligned PWM signals to be generated with programmable delay and phase shift between respective pulses. While the frequency is determined by the value of the TIMx\_ARR register, the duty cycle and delay are determined by the two TIMx\_CCRx registers. The resulting signals, OCxREFC, are made of an OR or AND logical combination of two reference PWMs:

- OC1REFC (or OC2REFC) is controlled by TIMx\_CCR1 and TIMx\_CCR2
- OC3REFC (or OC4REFC) is controlled by TIMx\_CCR3 and TIMx\_CCR4

Combined PWM mode can be selected independently on two channels (one OCx output per pair of CCR registers) by writing '1100' (Combined PWM mode 1) or '1101' (Combined PWM mode 2) in the OCxM bits in the TIMx\_CCMRx register.

When a given channel is used as combined PWM channel, its complementary channel must be configured in the opposite PWM mode (for instance, one in Combined PWM mode 1 and the other in Combined PWM mode 2).

**Note:** The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

Figure 262 represents an example of signals that can be generated using Asymmetric PWM mode, obtained with the following configuration:

- Channel 1 is configured in Combined PWM mode 2,
- Channel 2 is configured in PWM mode 1,
- Channel 3 is configured in Combined PWM mode 2,
- Channel 4 is configured in PWM mode 1.

Figure 262. Combined PWM mode on channel 1 and 3

### 30.3.14 Combined 3-phase PWM mode

Combined 3-phase PWM mode allows one to three center-aligned PWM signals to be generated with a single programmable signal ANDed in the middle of the pulses. The OC5REF signal is used to define the resulting combined signal. The 3-bits GC5C[3:1] in the TIMx\_CCR5 allow selection on which reference signal the OC5REF is combined. The resulting signals, OCxREFC, are made of an AND logical combination of two reference PWMs:

- If GC5C1 is set, OC1REFC is controlled by TIMx\_CCR1 and TIMx\_CCR5
- If GC5C2 is set, OC2REFC is controlled by TIMx\_CCR2 and TIMx\_CCR5
- If GC5C3 is set, OC3REFC is controlled by TIMx\_CCR3 and TIMx\_CCR5

Combined 3-phase PWM mode can be selected independently on channels 1 to 3 by setting at least one of the 3-bits GC5C[3:1].

**Figure 263. 3-phase combined PWM signals with multiple trigger pulses per period**

The TRGO2 waveform shows how the ADC can be synchronized on given 3-phase PWM signals. Refer to [Section 30.3.27: ADC synchronization](#) for more details.

### 30.3.15 Complementary outputs and dead-time insertion

The advanced-control timers (TIM1/TIM8) can output two complementary signals and manage the switching-off and the switching-on instants of the outputs.

This time is generally known as dead-time and it has to be adjusted depending on the devices that are connected to the outputs and their characteristics (intrinsic delays of level-shifters, delays due to power switches...)

The polarity of the outputs (main output OCx or complementary OCxN) can be selected independently for each output. This is done by writing to the CCxP and CCxNP bits in the TIMx\_CCER register.

The complementary signals OCx and OCxN are activated by a combination of several control bits: the CCxE and CCxNE bits in the TIMx\_CCER register and the MOE, OISx, OISxN, OSSI and OSSR bits in the TIMx\_BDTR and TIMx\_CR2 registers. Refer to [Table 199: Output control bits for complementary OCx and OCxN channels with break feature on page 976](#) for more details. In particular, the dead-time is activated when switching to the idle state (MOE falling down to 0).

Dead-time insertion is enabled by setting both CCxE and CCxNE bits, and the MOE bit if the break circuit is present. There is one 10-bit dead-time generator for each channel. From a reference waveform OCxREF, it generates 2 outputs OCx and OCxN. If OCx and OCxN are active high:

- The OCx output signal is the same as the reference signal except for the rising edge, which is delayed relative to the reference rising edge.
- The OCxN output signal is the opposite of the reference signal except for the rising edge, which is delayed relative to the reference falling edge.

If the delay is greater than the width of the active output (OCx or OCxN) then the corresponding pulse is not generated.

The following figures show the relationships between the output signals of the dead-time generator and the reference signal OCxREF. (we suppose CCxP=0, CCxNP=0, MOE=1, CCxE=1 and CCxNE=1 in these examples)

**Figure 264. Complementary output with dead-time insertion**

**Figure 265. Dead-time waveforms with delay greater than the negative pulse**

**Figure 266. Dead-time waveforms with delay greater than the positive pulse**

The dead-time delay is the same for each of the channels and is programmable with the DTG bits in the TIMx\_BDTR register. Refer to [Section 30.4.20: TIMx break and dead-time register \(TIMx\\_BDTR\)\(x = 1, 8\)](#) for delay calculation.

### Re-directing OCxREF to OCx or OCxN

In output mode (forced, output compare or PWM), OCxREF can be re-directed to the OCx output or to OCxN output by configuring the CCxE and CCxNE bits in the TIMx\_CCER register.

This allows a specific waveform to be sent (such as PWM or static active level) on one output while the complementary remains at its inactive level. Other alternative possibilities are to have both outputs at inactive level or both outputs active and complementary with dead-time.

**Note:** *When only OCxN is enabled (CCxE=0, CCxNE=1), it is not complemented and becomes active as soon as OCxREF is high. For example, if CCxNP=0 then OCxN=OCxRef. On the other hand, when both OCx and OCxN are enabled (CCxE=CCxNE=1) OCx becomes active when OCxREF is high whereas OCxN is complemented and becomes active when OCxREF is low.*

### 30.3.16 Using the break function

The purpose of the break function is to protect power switches driven by PWM signals generated with the TIM1 and TIM8 timers. The two break inputs are usually connected to fault outputs of power stages and 3-phase inverters. When activated, the break circuitry shuts down the PWM outputs and forces them to a predefined safe state. A number of internal MCU events can also be selected to trigger an output shut-down.

The break features two channels. A break channel which gathers both system-level fault (clock failure, parity error,...) and application fault (from input pins and built-in comparator), and can force the outputs to a predefined level (either active or inactive) after a deadtime duration. A break2 channel which only includes application faults and is able to force the outputs to an inactive state.

The output enable signal and output levels during break are depending on several control bits:

- the MOE bit in TIMx\_BDTR register allows the outputs to be enabled/disabled by software and is reset in case of break or break2 event.
- the OSSI bit in the TIMx\_BDTR register defines whether the timer controls the output in inactive state or releases the control to the GPIO controller (typically to have it in Hi-Z mode)
- the OISx and OISxN bits in the TIMx\_CR2 register which are setting the output shut-down level, either active or inactive. The OCx and OCxN outputs cannot be set both to active level at a given time, whatever the OISx and OISxN values. Refer to [Table 199: Output control bits for complementary OCx and OCxN channels with break feature on page 976](#) for more details.

When exiting from reset, the break circuit is disabled and the MOE bit is low. The break functions can be enabled by setting the BKE and BK2E bits in the TIMx\_BDTR register. The break input polarities can be selected by configuring the BKP and BK2P bits in the same register. BKE/BK2E and BKP/BK2P can be modified at the same time. When the BKE/BK2E and BKP/BK2P bits are written, a delay of 1 APB clock cycle is applied before the writing is effective. Consequently, it is necessary to wait 1 APB clock period to correctly read back the bit after the write operation.

Because MOE falling edge can be asynchronous, a resynchronization circuit has been inserted between the actual signal (acting on the outputs) and the synchronous control bit (accessed in the TIMx\_BDTR register). It results in some delays between the asynchronous and the synchronous signals. In particular, if MOE is set to 1 whereas it was low, a delay must be inserted (dummy instruction) before reading it correctly. This is because the write acts on the asynchronous signal whereas the read reflects the synchronous signal.

The break can be generated from multiple sources which can be individually enabled and with programmable edge sensitivity, using the TIMx\_OR2 and TIMx\_OR3 registers.

The sources for break (BRK) channel are:

- An external source connected to one of the BKIN pin (as per selection done in the GPIO alternate function registers), with polarity selection and optional digital filtering
- An internal source:
  - the Cortex®-M4 LOCKUP output
  - the PVD output
  - the SRAM parity error signal
  - a flash memory ECC dual error detection
  - a clock failure event generated by the CSS detector
  - the output from a comparator, with polarity selection and optional digital filtering
  - the analog watchdog output of the DFSDM1 peripheral

The sources for break2 (BRK2) are:

- An external source connected to one of the BKIN pin (as per selection done in the GPIO alternate function registers), with polarity selection and optional digital filtering
- An internal source coming from a comparator output.

Break events can also be generated by software using BG and B2G bits in the TIMx\_EGR register. The software break generation using BG and B2G is active whatever the BKE and BK2E enable bits values.

All sources are ORed before entering the timer BRK or BRK2 inputs, as per [Figure 267](#) below.

**Figure 267. Break and Break2 circuitry overview**

**Note:** An asynchronous (clockless) operation is only guaranteed when the programmable filter is disabled. If it is enabled, a fail safe clock mode (for example by using the internal PLL and/or the CSS) must be used to guarantee that break events are handled.

When one of the breaks occurs (selected level on one of the break inputs):

- The MOE bit is cleared asynchronously, putting the outputs in inactive state, idle state or even releasing the control to the GPIO controller (selected by the OSSR bit). This feature is enabled even if the MCU oscillator is off.
- Each output channel is driven with the level programmed in the OISx bit in the TIMx\_CR2 register as soon as MOE=0. If OSSR=0, the timer releases the output control (taken over by the GPIO controller), otherwise the enable output remains high.
- When complementary outputs are used:
  - The outputs are first put in inactive state (depending on the polarity). This is done asynchronously so that it works even if no clock is provided to the timer.
  - If the timer clock is still present, then the dead-time generator is reactivated in order to drive the outputs with the level programmed in the OISx and OISxN bits after a dead-time. Even in this case, OCx and OCxN cannot be driven to their active level together. Note that because of the resynchronization on MOE, the dead-time duration is slightly longer than usual (around 2 ck\_tim clock cycles).
  - If OSSR=0, the timer releases the output control (taken over by the GPIO controller which forces a Hi-Z state), otherwise the enable outputs remain or become high as soon as one of the CCxE or CCxNE bits is high.
- The break status flag (SBIF, BIF and B2IF bits in the TIMx\_SR register) is set. An interrupt is generated if the BIE bit in the TIMx\_DIER register is set.
- If the AOE bit in the TIMx\_BDTR register is set, the MOE bit is automatically set again at the next update event (UEV). As an example, this can be used to perform a regulation. Otherwise, MOE remains low until the application sets it to '1' again. In this case, it can be used for security and the break input can be connected to an alarm from power drivers, thermal sensors or any security components.

**Note:** *If the MOE is reset by the CPU while the AOE bit is set, the outputs are in idle state and forced to inactive level or Hi-Z depending on OSSR value.  
If both the MOE and AOE bits are reset by the CPU, the outputs are in disabled state and driven with the level programmed in the OISx bit in the TIMx\_CR2 register.*

**Note:** *The break inputs are active on level. Thus, the MOE cannot be set while the break input is active (neither automatically nor by software). In the meantime, the status flag BIF and B2IF cannot be cleared.*

In addition to the break input and the output management, a write protection has been implemented inside the break circuit to safeguard the application. It allows the configuration of several parameters to be frozen (dead-time duration, OCx/OCxN polarities and state when disabled, OCxM configurations, break enable and polarity). The application can choose from 3 levels of protection selected by the LOCK bits in the TIMx\_BDTR register. Refer to [Section 30.4.20: TIMx break and dead-time register \(TIMx\\_BDTR\)\(x = 1, 8\)](#). The LOCK bits can be written only once after an MCU reset.

[Figure 268](#) shows an example of behavior of the outputs in response to a break.

**Figure 268. Various output behavior in response to a break event on BRK (OSS1 = 1)**

- The two break inputs have different behaviors on timer outputs:
- The BRK input can either disable (inactive state) or force the PWM outputs to a predefined safe state.
  - BRK2 can only disable (inactive state) the PWM outputs.

The BRK has a higher priority than BRK2 input, as described in [Table 196](#).

*Note:* BRK2 must only be used with OSSR = OSSl = 1.

Table 196. Behavior of timer outputs versus BRK/BRK2 inputs

| BRK      | BRK2   | Timer outputs state                                                                                                                                                              | Typical use case                |                                 |
|----------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------|---------------------------------|
|          |        |                                                                                                                                                                                  | OCxN output (low side switches) | OCx output (high side switches) |
| Active   | X      | <ul style="list-style-type: none"><li>– Inactive then forced output state (after a deadtime)</li><li>– Outputs disabled if OSSl = 0 (control taken over by GPIO logic)</li></ul> | ON after deadtime insertion     | OFF                             |
| Inactive | Active | Inactive                                                                                                                                                                         | OFF                             | OFF                             |

[Figure 269](#) gives an example of OCx and OCxN output behavior in case of active signals on BRK and BRK2 inputs. In this case, both outputs have active high polarities (CCxP = CCxNP = 0 in TIMx\_CCER register).

Figure 269. PWM output state following BRK and BRK2 pins assertion (OSSl=1)

**Figure 270. PWM output state following BRK assertion (OSSI=0)**

### 30.3.17 Bidirectional break inputs

Beside regular digital break inputs and internal break events coming from the comparators, the timer 1 and 8 are featuring bidirectional break inputs/outputs combining the two sources, as represented on [Figure 271](#).

The TIMx\_BKINy\_COMPz pins are combining the COMPz output (to be configured in open drain) and the Timerx's TIMx\_BKINy input. They allow to have:

- A global break information available for external MCUs or gate drivers shut down inputs, with a single-pin.
- An internal comparator and multiple external open drain comparators outputs ORed together and triggering a break event, when the multiple internal and external break inputs must be merged.

**Figure 271. Output redirection**

### 30.3.18 Clearing the OCxREF signal on an external event

The OCxREF signal of a given channel can be cleared when a high level is applied on the ocref\_clr\_int input (OCxCE enable bit in the corresponding TIMx\_CCMRx register set to 1). OCxREF remains low until the next transition to the active state, on the following PWM cycle. This function can only be used in Output compare and PWM modes. It does not work in Forced mode. The OCREF\_CLR input is not connected (NC) in this product. The OCCS bit must be set to work in OCxREF clearing mode.

When ETRF is chosen, ETR must be configured as follows:

1. The External Trigger Prescaler should be kept off: bits ETPS[1:0] of the TIMx\_SMCR register set to '00'.
2. The external clock mode 2 must be disabled: bit ECE of the TIMx\_SMCR register set to '0'.
3. The External Trigger Polarity (ETP) and the External Trigger Filter (ETF) can be configured according to the user needs.

Figure 272 shows the behavior of the OCxREF signal when the ETRF Input becomes High, for both values of the enable bit OCxCE. In this example, the timer TIMx is programmed in PWM mode.

Figure 272. Clearing TIMx OCxREF

**Note:** In case of a PWM with a 100% duty cycle (if  $CCR_x > ARR$ ), then OCxREF is enabled again at the next counter overflow.

### 30.3.19 6-step PWM generation

When complementary outputs are used on a channel, preload bits are available on the OCxM, CCxE and CCxNE bits. The preload bits are transferred to the shadow bits at the COM commutation event. Thus one can program in advance the configuration for the next step and change the configuration of all the channels at the same time. COM can be generated by software by setting the COM bit in the TIMx\_EGR register or by hardware (on TRGI rising edge).

A flag is set when the COM event occurs (COMIF bit in the TIMx\_SR register), which can generate an interrupt (if the COMIE bit is set in the TIMx\_DIER register) or a DMA request (if the COMDE bit is set in the TIMx\_DIER register).

The [Figure 273](#) describes the behavior of the OCx and OCxN outputs when a COM event occurs, in 3 different examples of programmed configurations.

**Figure 273. 6-step generation, COM example (OSSR=1)**

### 30.3.20 One-pulse mode

One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. One-pulse mode is selected by setting the OPM bit in the TIMx\_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be:

- In upcounting:  $CNT < CCRx \leq ARR$  (in particular,  $0 < CCRx$ )
- In downcounting:  $CNT > CCRx$

**Figure 274. Example of one pulse mode.**

For example one may want to generate a positive pulse on OC1 with a length of  $t_{PULSE}$  and after a delay of  $t_{DELAY}$  as soon as a positive edge is detected on the TI2 input pin.

Let's use TI2FP2 as trigger 1:

1. Map TI2FP2 to TI2 by writing  $CC2S='01'$  in the TIMx\_CCMR1 register.
2. TI2FP2 must detect a rising edge, write  $CC2P='0'$  and  $CC2NP='0'$  in the TIMx\_CCER register.
3. Configure TI2FP2 as trigger for the slave mode controller (TRGI) by writing  $TS=110$  in the TIMx\_SMCR register.
4. TI2FP2 is used to start the counter by writing  $SMS$  to '110' in the TIMx\_SMCR register (trigger mode).

The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler).

- The  $t_{\text{DELAY}}$  is defined by the value written in the TIMx\_CCR1 register.
- The  $t_{\text{PULSE}}$  is defined by the difference between the auto-reload value and the compare value (TIMx\_ARR - TIMx\_CCR1).
- Let's say one want to build a waveform with a transition from '0' to '1' when a compare match occurs and a transition from '1' to '0' when the counter reaches the auto-reload value. To do this PWM mode 2 must be enabled by writing OC1M=111 in the TIMx\_CCMR1 register. Optionally the preload registers can be enabled by writing OC1PE='1' in the TIMx\_CCMR1 register and ARPE in the TIMx\_CR1 register. In this case one has to write the compare value in the TIMx\_CCR1 register, the auto-reload value in the TIMx\_ARR register, generate an update by setting the UG bit and wait for external trigger event on TI2. CC1P is written to '0' in this example.

In our example, the DIR and CMS bits in the TIMx\_CR1 register should be low.

Since only 1 pulse (Single mode) is needed, a 1 must be written in the OPM bit in the TIMx\_CR1 register to stop the counter at the next update event (when the counter rolls over from the auto-reload value back to 0). When OPM bit in the TIMx\_CR1 register is set to '0', so the Repetitive Mode is selected.

Particular case: OCx fast enable:

In One-pulse mode, the edge detection on TIx input set the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations and it limits the minimum delay  $t_{\text{DELAY min}}$  we can get.

If one wants to output a waveform with the minimum delay, the OCxFE bit can be set in the TIMx\_CCMRx register. Then OCxRef (and OCx) are forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

### 30.3.21 Retriggerable one pulse mode

This mode allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length, but with the following differences with Non-retriggerable one pulse mode described in [Section 30.3.20](#):

- The pulse starts as soon as the trigger occurs (no programmable delay)
- The pulse is extended if a new trigger occurs before the previous one is completed

The timer must be in Slave mode, with the bits SMS[3:0] = '1000' (Combined Reset + trigger mode) in the TIMx\_SMCR register, and the OCxM[3:0] bits set to '1000' or '1001' for retriggerable OPM mode 1 or 2.

If the timer is configured in Up-counting mode, the corresponding CCRx must be set to 0 (the ARR register sets the pulse length). If the timer is configured in Down-counting mode, CCRx must be above or equal to ARR.

*Note: The OCxM[3:0] and SMS[3:0] bit fields are split into two parts for compatibility reasons, the most significant bit are not contiguous with the 3 least significant ones.*

*This mode must not be used with center-aligned PWM modes. It is mandatory to have CMS[1:0] = 00 in TIMx\_CR1.*

Figure 275. Retriggerable one pulse mode

### 30.3.22 Encoder interface mode

To select Encoder Interface mode write SMS='001' in the TIMx\_SMCR register if the counter is counting on TI2 edges only, SMS='010' if it is counting on TI1 edges only and SMS='011' if it is counting on both TI1 and TI2 edges.

Select the TI1 and TI2 polarity by programming the CC1P and CC2P bits in the TIMx\_CCER register. When needed, the input filter can be programmed as well. CC1NP and CC2NP must be kept low.

The two inputs TI1 and TI2 are used to interface to a quadrature encoder. Refer to [Table 197](#). The counter is clocked by each valid transition on TI1FP1 or TI2FP2 (TI1 and TI2 after input filter and polarity selection, TI1FP1=TI1 if not filtered and not inverted, TI2FP2=TI2 if not filtered and not inverted) assuming that it is enabled (CEN bit in TIMx\_CR1 register written to '1'). The sequence of transitions of the two inputs is evaluated and generates count pulses as well as the direction signal. Depending on the sequence the counter counts up or down, the DIR bit in the TIMx\_CR1 register is modified by hardware accordingly. The DIR bit is calculated at each transition on any input (TI1 or TI2), whatever the counter is counting on TI1 only, TI2 only or both TI1 and TI2.

Encoder interface mode acts simply as an external clock with direction selection. This means that the counter just counts continuously between 0 and the auto-reload value in the TIMx\_ARR register (0 to ARR or ARR down to 0 depending on the direction). So the TIMx\_ARR must be configured before starting. In the same way, the capture, compare, repetition counter, trigger output features continue to work as normal. Encoder mode and External clock mode 2 are not compatible and must not be selected together.

**Note:** *The prescaler must be set to zero when encoder mode is enabled*

In this mode, the counter is modified automatically following the speed and the direction of the quadrature encoder and its content, therefore, always represents the encoder's position. The count direction correspond to the rotation direction of the connected sensor. The table summarizes the possible combinations, assuming TI1 and TI2 do not switch at the same time.

Table 197. Counting direction versus encoder signals

| Active edge             | Level on opposite signal (TI1FP1 for TI2, TI2FP2 for TI1) | TI1FP1 signal |          | TI2FP2 signal |          |
|-------------------------|-----------------------------------------------------------|---------------|----------|---------------|----------|
|                         |                                                           | Rising        | Falling  | Rising        | Falling  |
| Counting on TI1 only    | High                                                      | Down          | Up       | No Count      | No Count |
|                         | Low                                                       | Up            | Down     | No Count      | No Count |
| Counting on TI2 only    | High                                                      | No Count      | No Count | Up            | Down     |
|                         | Low                                                       | No Count      | No Count | Down          | Up       |
| Counting on TI1 and TI2 | High                                                      | Down          | Up       | Up            | Down     |
|                         | Low                                                       | Up            | Down     | Down          | Up       |

A quadrature encoder can be connected directly to the MCU without external interface logic. However, comparators are normally be used to convert the encoder's differential outputs to digital signals. This greatly increases noise immunity. The third encoder output which indicate the mechanical zero position, may be connected to an external interrupt input and trigger a counter reset.

The [Figure 276](#) gives an example of counter operation, showing count signal generation and direction control. It also shows how input jitter is compensated where both edges are selected. This might occur if the sensor is positioned near to one of the switching points. For this example we assume that the configuration is the following:

- CC1S='01' (TIMx\_CCMR1 register, TI1FP1 mapped on TI1).
- CC2S='01' (TIMx\_CCMR1 register, TI2FP2 mapped on TI2)
- CC1P='0' and CC1NP='0' (TIMx\_CCER register, TI1FP1 non-inverted, TI1FP1=TI1).
- CC2P='0' and CC2NP='0' (TIMx\_CCER register, TI1FP2 non-inverted, TI1FP2= TI2).
- SMS='011' (TIMx\_SMCR register, both inputs are active on both rising and falling edges).
- CEN='1' (TIMx\_CR1 register, Counter enabled).

Figure 276. Example of counter operation in encoder interface mode.

MS33107V1

Figure 277 gives an example of counter behavior when TI1FP1 polarity is inverted (same configuration as above except CC1P='1').

**Figure 277. Example of encoder interface mode with TI1FP1 polarity inverted.**

The timer, when configured in Encoder Interface mode provides information on the sensor's current position. Dynamic information can be obtained (speed, acceleration, deceleration) by measuring the period between two encoder events using a second timer configured in capture mode. The output of the encoder which indicates the mechanical zero can be used for this purpose. Depending on the time between two events, the counter can also be read at regular times. This can be done by latching the counter value into a third input capture register if available (then the capture signal must be periodic and can be generated by another timer). when available, it is also possible to read its value through a DMA request.

The IUFREMAP bit in the TIMx\_CR1 register forces a continuous copy of the update interrupt flag (UIF) into the timer counter register's bit 31 (TIMxCNT[31]). This allows both the counter value and a potential roll-over condition signaled by the UIFCPY flag to be read in an atomic way. It eases the calculation of angular speed by avoiding race conditions caused, for instance, by a processing shared between a background task (counter reading) and an interrupt (update interrupt).

There is no latency between the UIF and UIFCPY flag assertions.

In 32-bit timer implementations, when the IUFREMAP bit is set, bit 31 of the counter is overwritten by the UIFCPY flag upon read access (the counter's most significant bit is only accessible in write mode).

### 30.3.23 UIF bit remapping

The IUFREMAP bit in the TIMx\_CR1 register forces a continuous copy of the Update Interrupt Flag UIF into the timer counter register's bit 31 (TIMxCNT[31]). This allows both the counter value and a potential roll-over condition signaled by the UIFCPY flag to be read in an atomic way. In particular cases, it can ease the calculations by avoiding race conditions, caused for instance by a processing shared between a background task (counter reading) and an interrupt (Update Interrupt).

There is no latency between the UIF and UIFCPY flags assertion.

### 30.3.24 Timer input XOR function

The TI1S bit in the TIMx\_CR2 register, allows the input filter of channel 1 to be connected to the output of an XOR gate, combining the three input pins TIMx\_CH1, TIMx\_CH2 and TIMx\_CH3.

The XOR output can be used with all the timer input functions such as trigger or input capture. It is convenient to measure the interval between edges on two input signals, as per [Figure 278](#) below.

**Figure 278. Measuring time interval between edges on 3 signals**

### 30.3.25 Interfacing with Hall sensors

This is done using the advanced-control timers (TIM1 or TIM8) to generate PWM signals to drive the motor and another timer TIMx (TIM2, TIM3, TIM4) referred to as “interfacing timer” in [Figure 279](#). The “interfacing timer” captures the 3 timer input pins (CC1, CC2, CC3) connected through a XOR to the TI1 input channel (selected by setting the TI1S bit in the TIMx\_CR2 register).

The slave mode controller is configured in reset mode; the slave input is TI1F\_ED. Thus, each time one of the 3 inputs toggles, the counter restarts counting from 0. This creates a time base triggered by any change on the Hall inputs.

On the “interfacing timer”, capture/compare channel 1 is configured in capture mode, capture signal is TRC (See [Figure 252: Capture/compare channel \(example: channel 1 input stage\) on page 919](#)). The captured value, which corresponds to the time elapsed between 2 changes on the inputs, gives information about motor speed.

The “interfacing timer” can be used in output mode to generate a pulse which changes the configuration of the channels of the advanced-control timer (TIM1 or TIM8) (by triggering a COM event). The TIM1 timer is used to generate PWM signals to drive the motor. To do this, the interfacing timer channel must be programmed so that a positive pulse is generated after a programmed delay (in output compare or PWM mode). This pulse is sent to the advanced-control timer (TIM1 or TIM8) through the TRGO output.

Example: one wants to change the PWM configuration of the advanced-control timer TIM1 after a programmed delay each time a change occurs on the Hall inputs connected to one of the TIMx timers.

- Configure 3 timer inputs ORed to the TI1 input channel by writing the TI1S bit in the TIMx\_CR2 register to '1',
- Program the time base: write the TIMx\_ARR to the max value (the counter must be cleared by the TI1 change. Set the prescaler to get a maximum counter period longer than the time between 2 changes on the sensors,
- Program the channel 1 in capture mode (TRC selected): write the CC1S bits in the TIMx\_CCMR1 register to '01'. The digital filter can also be programmed if needed,
- Program the channel 2 in PWM 2 mode with the desired delay: write the OC2M bits to '111' and the CC2S bits to '00' in the TIMx\_CCMR1 register,
- Select OC2REF as trigger output on TRGO: write the MMS bits in the TIMx\_CR2 register to '101',

In the advanced-control timer TIM1, the right ITR input must be selected as trigger input, the timer is programmed to generate PWM signals, the capture/compare control signals are preloaded (CCPC=1 in the TIMx\_CR2 register) and the COM event is controlled by the trigger input (CCUS=1 in the TIMx\_CR2 register). The PWM control bits (CCxE, OCxM) are written after a COM event for the next step (this can be done in an interrupt subroutine generated by the rising edge of OC2REF).

The [Figure 279](#) describes this example.

Figure 279. Example of Hall sensor interface

### 30.3.26 Timer synchronization

The TIMx timers are linked together internally for timer synchronization or chaining. Refer to [Section 31.3.19: Timer synchronization](#) for details. They can be synchronized in several modes: Reset mode, Gated mode, and Trigger mode.

#### Slave mode: Reset mode

The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIMx\_CR1 register is low, an update event UEV is generated. Then all the preloaded registers (TIMx\_ARR, TIMx\_CCRx) are updated.

In the following example, the upcounter is cleared in response to a rising edge on TI1 input:

- Configure the channel 1 to detect rising edges on TI1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S = 01 in the TIMx\_CCMR1 register. Write CC1P=0 and CC1NP='0' in TIMx\_CCER register to validate the polarity (and detect rising edges only).
- Configure the timer in reset mode by writing SMS=100 in TIMx\_SMCR register. Select TI1 as the input source by writing TS=101 in TIMx\_SMCR register.
- Start the counter by writing CEN=1 in the TIMx\_CR1 register.

The counter starts counting on the internal clock, then behaves normally until TI1 rising edge. When TI1 rises, the counter is cleared and restarts from 0. In the meantime, the trigger flag is set (TIF bit in the TIMx\_SR register) and an interrupt request, or a DMA request can be sent if enabled (depending on the TIE and TDE bits in TIMx\_DIER register).

The following figure shows this behavior when the auto-reload register TIMx\_ARR=0x36. The delay between the rising edge on TI1 and the actual reset of the counter is due to the resynchronization circuit on TI1 input.

**Figure 280. Control circuit in reset mode**

### Slave mode: Gated mode

The counter can be enabled depending on the level of a selected input.

In the following example, the upcounter counts only when TI1 input is low:

- Configure the channel 1 to detect low levels on TI1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S=01 in TIMx\_CCMR1 register. Write CC1P=1 and CC1NP=0' in TIMx\_CCER register to validate the polarity (and detect low level only).
- Configure the timer in gated mode by writing SMS=101 in TIMx\_SMCR register. Select TI1 as the input source by writing TS=101 in TIMx\_SMCR register.
- Enable the counter by writing CEN=1 in the TIMx\_CR1 register (in gated mode, the counter doesn't start if CEN=0, whatever is the trigger input level).

The counter starts counting on the internal clock as long as TI1 is low and stops as soon as TI1 becomes high. The TIF flag in the TIMx\_SR register is set both when the counter starts or stops.

The delay between the rising edge on TI1 and the actual stop of the counter is due to the resynchronization circuit on TI1 input.

**Figure 281. Control circuit in Gated mode**

### Slave mode: Trigger mode

The counter can start in response to an event on a selected input.

In the following example, the upcounter starts in response to a rising edge on TI2 input:

- Configure the channel 2 to detect rising edges on TI2. Configure the input filter duration (in this example, we do not need any filter, so we keep IC2F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC2S bits are configured to select the input capture source only, CC2S=01 in TIMx\_CCMR1

register. Write CC2P=1 and CC2NP=0 in TIMx\_CCER register to validate the polarity (and detect low level only).

- Configure the timer in trigger mode by writing SMS=110 in TIMx\_SMCR register. Select TI2 as the input source by writing TS=110 in TIMx\_SMCR register.

When a rising edge occurs on TI2, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on TI2 and the actual start of the counter is due to the resynchronization circuit on TI2 input.

**Figure 282. Control circuit in trigger mode**

### Slave mode: Combined reset + trigger mode

In this case, a rising edge of the selected trigger input (TRGI) reinitializes the counter, generates an update of the registers, and starts the counter.

This mode is used for one-pulse mode.

### Slave mode: external clock mode 2 + trigger mode

The external clock mode 2 can be used in addition to another slave mode (except external clock mode 1 and encoder mode). In this case, the ETR signal is used as external clock input, and another input can be selected as trigger input (in reset mode, gated mode or trigger mode). It is recommended not to select ETR as TRGI through the TS bits of TIMx\_SMCR register.

In the following example, the upcounter is incremented at each rising edge of the ETR signal as soon as a rising edge of TI1 occurs:

1. Configure the external trigger input circuit by programming the TIMx\_SMCR register as follows:
  - ETF = 0000: no filter
  - ETPS = 00: prescaler disabled
  - ETP = 0: detection of rising edges on ETR and ECE=1 to enable the external clock mode 2.
2. Configure the channel 1 as follows, to detect rising edges on TI:
  - IC1F = 0000: no filter.
  - The capture prescaler is not used for triggering and does not need to be configured.
  - CC1S = 01 in TIMx\_CCMR1 register to select only the input capture source
  - CC1P = 0 and CC1NP = 0 in TIMx\_CCER register to validate the polarity (and detect rising edge only).
3. Configure the timer in trigger mode by writing SMS=110 in TIMx\_SMCR register. Select TI1 as the input source by writing TS=101 in TIMx\_SMCR register.

A rising edge on TI1 enables the counter and sets the TIF flag. The counter then counts on ETR rising edges.

The delay between the rising edge of the ETR signal and the actual reset of the counter is due to the resynchronization circuit on ETRP input.

**Figure 283. Control circuit in external clock mode 2 + trigger mode**

**Note:**

*The clock of the slave peripherals (timer, ADC, ...) receiving the TRGO or the TRGO2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.*

### 30.3.27 ADC synchronization

The timer can generate an ADC triggering event with various internal signals, such as reset, enable or compare events. It is also possible to generate a pulse issued by internal edge detectors, such as:

- Rising and falling edges of OC4ref
- Rising edge on OC5ref or falling edge on OC6ref

The triggers are issued on the TRGO2 internal line which is redirected to the ADC. There is a total of 16 possible events, which can be selected using the MMS2[3:0] bits in the TIMx\_CR2 register.

An example of an application for 3-phase motor drives is given in [Figure 263 on page 931](#).

*Note: The clock of the slave peripherals (timer, ADC, ...) receiving the TRGO or the TRGO2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.*

*Note: The clock of the ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the timer.*

### 30.3.28 DMA burst mode

The TIMx timers have the capability to generate multiple DMA requests upon a single event. The main purpose is to be able to re-program part of the timer multiple times without software overhead, but it can also be used to read several registers in a row, at regular intervals.

The DMA controller destination is unique and must point to the virtual register TIMx\_DMAR. On a given timer event, the timer launches a sequence of DMA requests (burst). Each write into the TIMx\_DMAR register is actually redirected to one of the timer registers.

The DBL[4:0] bits in the TIMx\_DCR register set the DMA burst length. The timer recognizes a burst transfer when a read or a write access is done to the TIMx\_DMAR address, i.e. the number of transfers (either in half-words or in bytes).

The DBA[4:0] bits in the TIMx\_DCR registers define the DMA base address for DMA transfers (when read/write access are done through the TIMx\_DMAR address). DBA is defined as an offset starting from the address of the TIMx\_CR1 register:

Example:

00000: TIMx\_CR1

00001: TIMx\_CR2

00010: TIMx\_SMCR

As an example, the timer DMA burst feature is used to update the contents of the CCRx registers (x = 2, 3, 4) upon an update event, with the DMA transferring half words into the CCRx registers.

This is done in the following steps:

1. Configure the corresponding DMA channel as follows:
  - DMA channel peripheral address is the DMAR register address
  - DMA channel memory address is the address of the buffer in the RAM containing the data to be transferred by DMA into CCRx registers.
  - Number of data to transfer = 3 (See note below).
  - Circular mode disabled.
2. Configure the DCR register by configuring the DBA and DBL bit fields as follows:  
DBL = 3 transfers, DBA = 0xE.
3. Enable the TIMx update DMA request (set the UDE bit in the DIER register).
4. Enable TIMx
5. Enable the DMA channel

This example is for the case where every CCRx register to be updated once. If every CCRx register is to be updated twice for example, the number of data to transfer should be 6. Let's take the example of a buffer in the RAM containing data1, data2, data3, data4, data5 and data6. The data is transferred to the CCRx registers as follows: on the first update DMA request, data1 is transferred to CCR2, data2 is transferred to CCR3, data3 is transferred to CCR4 and on the second update DMA request, data4 is transferred to CCR2, data5 is transferred to CCR3 and data6 is transferred to CCR4.

*Note:* A null value can be written to the reserved registers.

### 30.3.29 Debug mode

When the microcontroller enters debug mode (Cortex<sup>®</sup>-M4 core halted), the TIMx counter either continues to work normally or stops, depending on DBG\_TIMx\_STOP configuration bit in DBG module.

For safety purposes, when the counter is stopped, the outputs are disabled (as if the MOE bit was reset). The outputs can either be forced to an inactive state (OSSI bit = 1), or have their control taken over by the GPIO controller (OSSI bit = 0), typically to force a Hi-Z.

For more details, refer to section Debug support (DBG).

## 30.4 TIM1/TIM8 registers

Refer to for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

### 30.4.1 TIMx control register 1 (TIMx\_CR1)(x = 1, 8)

Address offset: 0x00

Reset value: 0x0000

| 15   | 14   | 13   | 12   | 11           | 10   | 9        | 8  | 7    | 6        | 5  | 4   | 3   | 2   | 1    | 0   |
|------|------|------|------|--------------|------|----------|----|------|----------|----|-----|-----|-----|------|-----|
| Res. | Res. | Res. | Res. | UIFRE<br>MAP | Res. | CKD[1:0] |    | ARPE | CMS[1:0] |    | DIR | OPM | URS | UDIS | CEN |
|      |      |      |      | rw           |      | rw       | rw | rw   | rw       | rw | rw  | rw  | rw  | rw   | rw  |

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 **UIFREMAP**: UIF status bit remapping

0: No remapping. UIF status bit is not copied to TIMx\_CNT register bit 31.

1: Remapping enabled. UIF status bit is copied to TIMx\_CNT register bit 31.

Bit 10 Reserved, must be kept at reset value.

Bits 9:8 **CKD[1:0]**: Clock division

This bit-field indicates the division ratio between the timer clock (CK\_INT) frequency and the dead-time and sampling clock ( $t_{DTS}$ ) used by the dead-time generators and the digital filters (ETR, TIx):

00:  $t_{DTS} = t_{CK\_INT}$

01:  $t_{DTS} = 2 * t_{CK\_INT}$

10:  $t_{DTS} = 4 * t_{CK\_INT}$

11: Reserved, do not program this value

*Note:*  $t_{DTS} = 1/f_{DTS}$ ,  $t_{CK\_INT} = 1/f_{CK\_INT}$ .

Bit 7 **ARPE**: Auto-reload preload enable

0: TIMx\_ARR register is not buffered

1: TIMx\_ARR register is buffered

Bits 6:5 **CMS[1:0]**: Center-aligned mode selection

00: Edge-aligned mode. The counter counts up or down depending on the direction bit (DIR).

01: Center-aligned mode 1. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx\_CCMRx register) are set only when the counter is counting down.

10: Center-aligned mode 2. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx\_CCMRx register) are set only when the counter is counting up.

11: Center-aligned mode 3. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx\_CCMRx register) are set both when the counter is counting up or down.

*Note:* Switch from edge-aligned mode to center-aligned mode as long as the counter is enabled (CEN=1) is not allowed

Bit 4 **DIR**: Direction

- 0: Counter used as upcounter
- 1: Counter used as downcounter

*Note: This bit is read only when the timer is configured in Center-aligned mode or Encoder mode.*

Bit 3 **OPM**: One pulse mode

- 0: Counter is not stopped at update event
- 1: Counter stops counting at the next update event (clearing the bit CEN)

Bit 2 **URS**: Update request source

This bit is set and cleared by software to select the UEV event sources.

0: Any of the following events generate an update interrupt or DMA request if enabled.

These events can be:

- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller

1: Only counter overflow/underflow generates an update interrupt or DMA request if enabled.

Bit 1 **UDIS**: Update disable

This bit is set and cleared by software to enable/disable UEV event generation.

0: UEV enabled. The Update (UEV) event is generated by one of the following events:

- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller

Buffered registers are then loaded with their preload values.

1: UEV disabled. The Update event is not generated, shadow registers keep their value (ARR, PSC, CCRx). However the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.

Bit 0 **CEN**: Counter enable

- 0: Counter disabled
- 1: Counter enabled

*Note: External clock, gated mode and encoder mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.*

### 30.4.2 TIMx control register 2 (TIMx\_CR2)(x = 1, 8)

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:20 **MMS2[3:0]**: Master mode selection 2

These bits allow the information to be sent to ADC for synchronization (TRGO2) to be selected. The combination is as follows:

0000: **Reset** - the UG bit from the TIMx\_EGR register is used as trigger output (TRGO2). If the reset is generated by the trigger input (slave mode controller configured in reset mode), the signal on TRGO2 is delayed compared to the actual reset.

0001: **Enable** - the Counter Enable signal CNT\_EN is used as trigger output (TRGO2). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic AND between the CEN control bit and the trigger input when configured in Gated mode. When the Counter Enable signal is controlled by the trigger input, there is a delay on TRGO2, except if the Master/Slave mode is selected (see the MSM bit description in TIMx\_SMCR register).

0010: **Update** - the update event is selected as trigger output (TRGO2). For instance, a master timer can then be used as a prescaler for a slave timer.

0011: **Compare pulse** - the trigger output sends a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or compare match occurs (TRGO2).

0100: **Compare** - OC1REFC signal is used as trigger output (TRGO2)

0101: **Compare** - OC2REFC signal is used as trigger output (TRGO2)

0110: **Compare** - OC3REFC signal is used as trigger output (TRGO2)

0111: **Compare** - OC4REFC signal is used as trigger output (TRGO2)

1000: **Compare** - OC5REFC signal is used as trigger output (TRGO2)

1001: **Compare** - OC6REFC signal is used as trigger output (TRGO2)

1010: **Compare Pulse** - OC4REFC rising or falling edges generate pulses on TRGO2

1011: **Compare Pulse** - OC6REFC rising or falling edges generate pulses on TRGO2

1100: **Compare Pulse** - OC4REFC or OC6REFC rising edges generate pulses on TRGO2

1101: **Compare Pulse** - OC4REFC rising or OC6REFC falling edges generate pulses on TRGO2

1110: **Compare Pulse** - OC5REFC or OC6REFC rising edges generate pulses on TRGO2

1111: **Compare Pulse** - OC5REFC rising or OC6REFC falling edges generate pulses on TRGO2

*Note: The clock of the slave timer or ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.*

Bit 19 Reserved, must be kept at reset value.

Bit 18 **OIS6**: Output Idle state 6 (OC6 output)

Refer to OIS1 bit

Bit 17 Reserved, must be kept at reset value.

Bit 16 **OIS5**: Output Idle state 5 (OC5 output)

Refer to OIS1 bit

Bit 15 Reserved, must be kept at reset value.

Bit 14 **OIS4**: Output Idle state 4 (OC4 output)

Refer to OIS1 bit

Bit 13 **OIS3N**: Output Idle state 3 (OC3N output)

Refer to OIS1N bit

- Bit 12 **OIS3**: Output Idle state 3 (OC3 output)  
Refer to OIS1 bit
- Bit 11 **OIS2N**: Output Idle state 2 (OC2N output)  
Refer to OIS1N bit
- Bit 10 **OIS2**: Output Idle state 2 (OC2 output)  
Refer to OIS1 bit
- Bit 9 **OIS1N**: Output Idle state 1 (OC1N output)  
0: OC1N=0 after a dead-time when MOE=0  
1: OC1N=1 after a dead-time when MOE=0  
*Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx\_BDTR register).*
- Bit 8 **OIS1**: Output Idle state 1 (OC1 output)  
0: OC1=0 (after a dead-time if OC1N is implemented) when MOE=0  
1: OC1=1 (after a dead-time if OC1N is implemented) when MOE=0  
*Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx\_BDTR register).*
- Bit 7 **TI1S**: TI1 selection  
0: The TIMx\_CH1 pin is connected to TI1 input  
1: The TIMx\_CH1, CH2 and CH3 pins are connected to the TI1 input (XOR combination)
- Bits 6:4 **MMS[2:0]**: Master mode selection  
These bits allow selected information to be sent in master mode to slave timers for synchronization (TRGO). The combination is as follows:  
000: **Reset** - the UG bit from the TIMx\_EGR register is used as trigger output (TRGO). If the reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on TRGO is delayed compared to the actual reset.  
001: **Enable** - the Counter Enable signal CNT\_EN is used as trigger output (TRGO). It is useful to start several timers at the same time or to control a window in which a slave timer is enable. The Counter Enable signal is generated by a logic AND between CEN control bit and the trigger input when configured in gated mode. When the Counter Enable signal is controlled by the trigger input, there is a delay on TRGO, except if the master/slave mode is selected (see the MSM bit description in TIMx\_SMCR register).  
010: **Update** - The update event is selected as trigger output (TRGO). For instance a master timer can then be used as a prescaler for a slave timer.  
011: **Compare Pulse** - The trigger output send a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or a compare match occurred. (TRGO).  
100: **Compare** - OC1REFC signal is used as trigger output (TRGO)  
101: **Compare** - OC2REFC signal is used as trigger output (TRGO)  
110: **Compare** - OC3REFC signal is used as trigger output (TRGO)  
111: **Compare** - OC4REFC signal is used as trigger output (TRGO)  
*Note: The clock of the slave timer or ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.*
- Bit 3 **CCDS**: Capture/compare DMA selection  
0: CCx DMA request sent when CCx event occurs  
1: CCx DMA requests sent when update event occurs

Bit 2 **CCUS**: Capture/compare control update selection

0: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit only

1: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit or when an rising edge occurs on TRGI

*Note: This bit acts only on channels that have a complementary output.*

Bit 1 Reserved, must be kept at reset value.

Bit 0 **CCPC**: Capture/compare preloaded control

0: CCxE, CCxNE and OCxM bits are not preloaded

1: CCxE, CCxNE and OCxM bits are preloaded, after having been written, they are updated only when a commutation event (COM) occurs (COMG bit set or rising edge detected on TRGI, depending on the CCUS bit).

*Note: This bit acts only on channels that have a complementary output.*

### 30.4.3 TIMx slave mode control register (TIMx\_SMCR)(x = 1, 8)

Address offset: 0x08

Bits 31:17 Reserved, must be kept at reset value.

Bit 15 **ETP**: External trigger polarity

This bit selects whether ETR or  $\overline{\text{ETR}}$  is used for trigger operations

0: ETR is non-inverted, active at high level or rising edge.

1: ETR is inverted, active at low level or falling edge.

Bit 14 **ECE**: External clock enable

This bit enables External clock mode 2.

0: External clock mode 2 disabled

1: External clock mode 2 enabled. The counter is clocked by any active edge on the ETRF signal.

*Note: Setting the ECE bit has the same effect as selecting external clock mode 1 with TRGI connected to ETRF (SMS=111 and TS=111).*

*It is possible to simultaneously use external clock mode 2 with the following slave modes: reset mode, gated mode and trigger mode. Nevertheless, TRGI must not be connected to ETRF in this case (TS bits must not be 111).*

*If external clock mode 1 and external clock mode 2 are enabled at the same time, the external clock input is ETRF.*

Bits 13:12 **ETPS[1:0]**: External trigger prescaler

External trigger signal ETRP frequency must be at most 1/4 of  $f_{CK\_INT}$  frequency. A prescaler can be enabled to reduce ETRP frequency. It is useful when inputting fast external clocks.

- 00: Prescaler OFF
- 01: ETRP frequency divided by 2
- 10: ETRP frequency divided by 4
- 11: ETRP frequency divided by 8

Bits 11:8 **ETF[3:0]**: External trigger filter

This bit-field then defines the frequency used to sample ETRP signal and the length of the digital filter applied to ETRP. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

- 0000: No filter, sampling is done at  $f_{DTS}$
- 0001:  $f_{SAMPLING}=f_{CK\_INT}$ , N=2
- 0010:  $f_{SAMPLING}=f_{CK\_INT}$ , N=4
- 0011:  $f_{SAMPLING}=f_{CK\_INT}$ , N=8
- 0100:  $f_{SAMPLING}=f_{DTS}/2$ , N=6
- 0101:  $f_{SAMPLING}=f_{DTS}/2$ , N=8
- 0110:  $f_{SAMPLING}=f_{DTS}/4$ , N=6
- 0111:  $f_{SAMPLING}=f_{DTS}/4$ , N=8
- 1000:  $f_{SAMPLING}=f_{DTS}/8$ , N=6
- 1001:  $f_{SAMPLING}=f_{DTS}/8$ , N=8
- 1010:  $f_{SAMPLING}=f_{DTS}/16$ , N=5
- 1011:  $f_{SAMPLING}=f_{DTS}/16$ , N=6
- 1100:  $f_{SAMPLING}=f_{DTS}/16$ , N=8
- 1101:  $f_{SAMPLING}=f_{DTS}/32$ , N=5
- 1110:  $f_{SAMPLING}=f_{DTS}/32$ , N=6
- 1111:  $f_{SAMPLING}=f_{DTS}/32$ , N=8

Bit 7 **MSM**: Master/slave mode

- 0: No action
- 1: The effect of an event on the trigger input (TRGI) is delayed to allow a perfect synchronization between the current timer and its slaves (through TRGO). It is useful if we want to synchronize several timers on a single external event.

Bits 6:4 **TS[2:0]**: Trigger selection

This bit-field selects the trigger input to be used to synchronize the counter.

- 000: Internal Trigger 0 (ITR0)
- 001: Internal Trigger 1 (ITR1)
- 010: Internal Trigger 2 (ITR2)
- 011: Internal Trigger 3 (ITR3)
- 100: TI1 Edge Detector (TI1F\_ED)
- 101: Filtered Timer Input 1 (TI1FP1)
- 110: Filtered Timer Input 2 (TI2FP2)
- 111: External Trigger input (ETRF)

See [Table 198: TIMx internal trigger connection on page 962](#) for more details on ITRx meaning for each Timer.

*Note:* These bits must be changed only when they are not used (e.g. when SMS=000) to avoid wrong edge detections at the transition.

*Note:* The other bit is at position 16 in the same register

Bit 3 **OCCE**: OCREF clear selection

This bit is used to select the OCREF clear source.

- 0: OCREF\_CLR\_INT is not connected (reserved configuration)
- 1: OCREF\_CLR\_INT is connected to ETRF

Bits 16, 2, 1, 0 **SMS[3:0]**: Slave mode selection

When external signals are selected the active edge of the trigger signal (TRGI) is linked to the polarity selected on the external input (refer to ETP bit in TIMx\_SMCR for tim\_etr\_in and CCxP/CCxNP bits in TIMx\_CCER register for tim\_ti1fp1 and tim\_ti2fp2).

0000: Slave mode disabled - if CEN = '1' then the prescaler is clocked directly by the internal clock.

0001: Encoder mode 1 - Counter counts up/down on TI1FP1 edge depending on TI2FP2 level.

0010: Encoder mode 2 - Counter counts up/down on TI2FP2 edge depending on TI1FP1 level.

0011: Encoder mode 3 - Counter counts up/down on both TI1FP1 and TI2FP2 edges depending on the level of the other input.

0100: Reset Mode - Rising edge of the selected trigger input (TRGI) reinitializes the counter and generates an update of the registers.

0101: Gated Mode - The counter clock is enabled when the trigger input (TRGI) is high. The counter stops (but is not reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

0110: Trigger Mode - The counter starts at a rising edge of the trigger TRGI (but it is not reset). Only the start of the counter is controlled.

0111: External Clock Mode 1 - Rising edges of the selected trigger (TRGI) clock the counter.

1000: Combined reset + trigger mode - Rising edge of the selected trigger input (TRGI) reinitializes the counter, generates an update of the registers and starts the counter.

Codes above 1000: Reserved.

*Note: The gated mode must not be used if TI1F\_ED is selected as the trigger input (TS=100). Indeed, TI1F\_ED outputs 1 pulse for each transition on TI1F, whereas the gated mode checks the level of the trigger signal.*

*Note: The clock of the slave peripherals (timer, ADC, ...) receiving the TRGO or the TRGO2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.*

**Table 198. TIMx internal trigger connection**

| Slave TIM | ITR0 (TS = 000) | ITR1 (TS = 001) | ITR2 (TS = 010) | ITR3 (TS = 011) |
|-----------|-----------------|-----------------|-----------------|-----------------|
| TIM1      | TIM15           | TIM2            | TIM3            | TIM4            |

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **CC6IF**: Compare 6 interrupt flag

Refer to CC1IF description (Note: Channel 6 can only be configured as output)

Bit 16 **CC5IF**: Compare 5 interrupt flag

Refer to CC1IF description (Note: Channel 5 can only be configured as output)

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **SBIF**: System Break interrupt flag

This flag is set by hardware as soon as the system break input goes active. It can be cleared by software if the system break input is not active.

This flag must be reset to re-start PWM operation.

0: No break event occurred.

1: An active level has been detected on the system break input. An interrupt is generated if BIE=1 in the TIMx\_DIER register.

Bit 12 **CC4OF**: Capture/Compare 4 overcapture flag

Refer to CC1OF description

Bit 11 **CC3OF**: Capture/Compare 3 overcapture flag

Refer to CC1OF description

Bit 10 **CC2OF**: Capture/Compare 2 overcapture flag

Refer to CC1OF description

Bit 9 **CC1OF**: Capture/Compare 1 overcapture flag

This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to '0'.

0: No overcapture has been detected.

1: The counter value has been captured in TIMx\_CCR1 register while CC1IF flag was already set

Bit 8 **B2IF**: Break 2 interrupt flag

This flag is set by hardware as soon as the break 2 input goes active. It can be cleared by software if the break 2 input is not active.

0: No break event occurred.

1: An active level has been detected on the break 2 input. An interrupt is generated if BIE=1 in the TIMx\_DIER register.

Bit 7 **BIF**: Break interrupt flag

This flag is set by hardware as soon as the break input goes active. It can be cleared by software if the break input is not active.

0: No break event occurred.

1: An active level has been detected on the break input. An interrupt is generated if BIE=1 in the TIMx\_DIER register.

Bit 6 **TIF**: Trigger interrupt flag

This flag is set by hardware on the TRG trigger event (active edge detected on TRGI input when the slave mode controller is enabled in all modes but gated mode. It is set when the counter starts or stops when gated mode is selected. It is cleared by software.

0: No trigger event occurred.

1: Trigger interrupt pending.

Bit 5 **COMIF**: COM interrupt flag

This flag is set by hardware on COM event (when Capture/compare Control bits - CCxE, CCxNE, OCxM - have been updated). It is cleared by software.

0: No COM event occurred.

1: COM interrupt pending.

Bit 4 **CC4IF**: Capture/Compare 4 interrupt flag

Refer to CC1IF description

Bit 3 **CC3IF**: Capture/Compare 3 interrupt flag

Refer to CC1IF description

Bit 2 **CC2IF**: Capture/Compare 2 interrupt flag

Refer to CC1IF description

Bit 1 **CC1IF**: Capture/Compare 1 interrupt flag

This flag is set by hardware. It is cleared by software (input capture or output compare mode) or by reading the TIMx\_CCR1 register (input capture mode only).

0: No compare match / No input capture occurred

1: A compare match or an input capture occurred.

**If channel CC1 is configured as output:** this flag is set when the content of the counter TIMx\_CNT matches the content of the TIMx\_CCR1 register. When the content of TIMx\_CCR1 is greater than the content of TIMx\_ARR, the CC1IF bit goes high on the counter overflow (in up-counting and up/down-counting modes) or underflow (in down-counting mode). There are 3 possible options for flag setting in center-aligned mode, refer to the CMS bits in the TIMx\_CR1 register for the full description.

**If channel CC1 is configured as input:** this bit is set when counter value has been captured in TIMx\_CCR1 register (an edge has been detected on IC1, as per the edge sensitivity defined with the CC1P and CC1NP bits setting, in TIMx\_CCER).

**Bit 0 UIF:** Update interrupt flag

This bit is set by hardware on an update event. It is cleared by software.

0: No update occurred.

1: Update interrupt pending. This bit is set by hardware when the registers are updated:

- At overflow or underflow regarding the repetition counter value (update if repetition counter = 0) and if the UDIS=0 in the TIMx\_CR1 register.
- When CNT is reinitialized by software using the UG bit in TIMx\_EGR register, if URS=0 and UDIS=0 in the TIMx\_CR1 register.
- When CNT is reinitialized by a trigger event (refer to [Section 30.4.3: TIMx slave mode control register \(TIMx\\_SMCR\)\(x = 1, 8\)](#)), if URS=0 and UDIS=0 in the TIMx\_CR1 register.

**30.4.6 TIMx event generation register (TIMx\_EGR)(x = 1, 8)**

Address offset: 0x14

Reset value: 0x0000

| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8   | 7  | 6  | 5    | 4    | 3    | 2    | 1    | 0  |

|      |      |      |      |      |      |      | w   | w  | w  | w    | w    | w    | w    | w    | w  |

Bits 15:9 Reserved, must be kept at reset value.

**Bit 8 B2G:** Break 2 generation

This bit is set by software in order to generate an event, it is automatically cleared by hardware.

0: No action

1: A break 2 event is generated. MOE bit is cleared and B2IF flag is set. Related interrupt can occur if enabled.

**Bit 7 BG:** Break generation

This bit is set by software in order to generate an event, it is automatically cleared by hardware.

0: No action

1: A break event is generated. MOE bit is cleared and BIF flag is set. Related interrupt or DMA transfer can occur if enabled.

**Bit 6 TG:** Trigger generation

This bit is set by software in order to generate an event, it is automatically cleared by hardware.

0: No action

1: The TIF flag is set in TIMx\_SR register. Related interrupt or DMA transfer can occur if enabled.

**Bit 5 COMG:** Capture/Compare control update generation

This bit can be set by software, it is automatically cleared by hardware

0: No action

1: When CCPC bit is set, it allows CCxE, CCxNE and OCxM bits to be updated.

*Note: This bit acts only on channels having a complementary output.*

**Bit 4 CC4G:** Capture/Compare 4 generation

Refer to CC1G description

**Bit 3 CC3G:** Capture/Compare 3 generation

Refer to CC1G description

Bit 2 **CC2G**: Capture/Compare 2 generation

Refer to CC1G description

Bit 1 **CC1G**: Capture/Compare 1 generation

This bit is set by software in order to generate an event, it is automatically cleared by hardware.

0: No action

1: A capture/compare event is generated on channel 1:

**If channel CC1 is configured as output:**

CC1IF flag is set, Corresponding interrupt or DMA request is sent if enabled.

**If channel CC1 is configured as input:**

The current value of the counter is captured in TIMx\_CCR1 register. The CC1IF flag is set, the corresponding interrupt or DMA request is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.

Bit 0 **UG**: Update generation

This bit can be set by software, it is automatically cleared by hardware.

0: No action

1: Reinitialize the counter and generates an update of the registers. The prescaler internal counter is also cleared (the prescaler ratio is not affected). The counter is cleared if the center-aligned mode is selected or if DIR=0 (upcounting), else it takes the auto-reload value (TIMx\_ARR) if DIR=1 (downcounting).

### 30.4.7 TIMx capture/compare mode register 1 (TIMx\_CCMR1)(x = 1, 8)

Address offset: 0x18

Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (e.g. channel 1 in input capture mode and channel 2 in output compare mode).

**Input capture mode:**

|           |      |      |      |             |      |           |      |           |      |      |      |             |      |           |      |
|-----------|------|------|------|-------------|------|-----------|------|-----------|------|------|------|-------------|------|-----------|------|

| Res.      | Res. | Res. | Res. | Res.        | Res. | Res.      | Res. | Res.      | Res. | Res. | Res. | Res.        | Res. | Res.      | Res. |
|           |      |      |      |             |      |           |      |           |      |      |      |             |      |           |      |
| 15        | 14   | 13   | 12   | 11          | 10   | 9         | 8    | 7         | 6    | 5    | 4    | 3           | 2    | 1         | 0    |
| IC2F[3:0] |      |      |      | IC2PSC[1:0] |      | CC2S[1:0] |      | IC1F[3:0] |      |      |      | IC1PSC[1:0] |      | CC1S[1:0] |      |
| rw        | rw   | rw   | rw   | rw          | rw   | rw        | rw   | rw        | rw   | rw   | rw   | rw          | rw   | rw        | rw   |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:12 **IC2F[3:0]**: Input capture 2 filter

Refer to IC1F[3:0] description.

Bits 11:10 **IC2PSC[1:0]**: Input capture 2 prescaler

Refer to IC1PSC[1:0] description.

Bits 9:8 **CC2S[1:0]**: Capture/Compare 2 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC2 channel is configured as output

01: CC2 channel is configured as input, IC2 is mapped on TI2

10: CC2 channel is configured as input, IC2 is mapped on TI1

11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note:* CC2S bits are writable only when the channel is OFF (CC2E = '0' in TIMx\_CCER).

Bits 7:4 **IC1F[3:0]**: Input capture 1 filter

This bit-field defines the frequency used to sample TI1 input and the length of the digital filter applied to TI1. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000: No filter, sampling is done at  $f_{DTS}$

0001:  $f_{SAMPLING}=f_{CK\_INT}$ , N=2

0010:  $f_{SAMPLING}=f_{CK\_INT}$ , N=4

0011:  $f_{SAMPLING}=f_{CK\_INT}$ , N=8

0100:  $f_{SAMPLING}=f_{DTS}/2$ , N=6

0101:  $f_{SAMPLING}=f_{DTS}/2$ , N=8

0110:  $f_{SAMPLING}=f_{DTS}/4$ , N=6

0111:  $f_{SAMPLING}=f_{DTS}/4$ , N=8

1000:  $f_{SAMPLING}=f_{DTS}/8$ , N=6

1001:  $f_{SAMPLING}=f_{DTS}/8$ , N=8

1010:  $f_{SAMPLING}=f_{DTS}/16$ , N=5

1011:  $f_{SAMPLING}=f_{DTS}/16$ , N=6

1100:  $f_{SAMPLING}=f_{DTS}/16$ , N=8

1101:  $f_{SAMPLING}=f_{DTS}/32$ , N=5

1110:  $f_{SAMPLING}=f_{DTS}/32$ , N=6

1111:  $f_{SAMPLING}=f_{DTS}/32$ , N=8

Bits 3:2 **IC1PSC[1:0]**: Input capture 1 prescaler

This bit-field defines the ratio of the prescaler acting on CC1 input (IC1). The prescaler is reset as soon as CC1E='0' (TIMx\_CCER register).

00: no prescaler, capture is done each time an edge is detected on the capture input

01: capture is done once every 2 events

10: capture is done once every 4 events

11: capture is done once every 8 events

Bits 1:0 **CC1S[1:0]**: Capture/Compare 1 Selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC1 channel is configured as output

01: CC1 channel is configured as input, IC1 is mapped on TI1

10: CC1 channel is configured as input, IC1 is mapped on TI2

11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note:* CC1S bits are writable only when the channel is OFF (CC1E = '0' in TIMx\_CCER).

### 30.4.8 TIMx capture/compare mode register 1 [alternate] (TIMx\_CCMR1)(x = 1, 8)

Address offset: 0x18

Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the

corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (e.g. channel 1 in input capture mode and channel 2 in output compare mode).

#### Output compare mode:

|           |           |      |      |           |           |           |         |           |           |      |      |           |           |           |         |
|-----------|-----------|------|------|-----------|-----------|-----------|---------|-----------|-----------|------|------|-----------|-----------|-----------|---------|

Bits 31:25 Reserved, must be kept at reset value.

Bits 23:17 Reserved, must be kept at reset value.

Bit 15 **OC2CE**: Output Compare 2 clear enable  
Refer to OC1CE description.

Bits 24, 14:12 **OC2M[3:0]**: Output Compare 2 mode  
Refer to OC1M[3:0] description.

Bit 11 **OC2PE**: Output Compare 2 preload enable  
Refer to OC1PE description.

Bit 10 **OC2FE**: Output Compare 2 fast enable  
Refer to OC1FE description.

Bits 9:8 **CC2S[1:0]**: Capture/Compare 2 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC2 channel is configured as output

01: CC2 channel is configured as input, IC2 is mapped on TI2

10: CC2 channel is configured as input, IC2 is mapped on TI1

11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode is working only if an internal trigger input is selected through the TS bit (TIMx\_SMCR register)

*Note: CC2S bits are writable only when the channel is OFF (CC2E = '0' in TIMx\_CCER).*

Bit 7 **OC1CE**: Output Compare 1 clear enable

0: OC1Ref is not affected by the ocref\_clr\_int signal

1: OC1Ref is cleared as soon as a High level is detected on ocref\_clr\_int signal  
(OCREF\_CLR input or ETRF input)

Bits 16, 6:4 **OC1M[3:0]**: Output Compare 1 mode

These bits define the behavior of the output reference signal OC1REF from which OC1 and OC1N are derived. OC1REF is active high whereas OC1 and OC1N active level depends on CC1P and CC1NP bits.

0000: Frozen - The comparison between the output compare register TIMx\_CCR1 and the counter TIMx\_CNT has no effect on the outputs. This mode can be used when the timer serves as a software timebase. When the frozen mode is enabled during timer operation, the output keeps the state (active or inactive) it had before entering the frozen state.

0001: Set channel 1 to active level on match. OC1REF signal is forced high when the counter TIMx\_CNT matches the capture/compare register 1 (TIMx\_CCR1).

0010: Set channel 1 to inactive level on match. OC1REF signal is forced low when the counter TIMx\_CNT matches the capture/compare register 1 (TIMx\_CCR1).

0011: Toggle - OC1REF toggles when TIMx\_CNT=TIMx\_CCR1.

0100: Force inactive level - OC1REF is forced low.

0101: Force active level - OC1REF is forced high.

0110: PWM mode 1 - In upcounting, channel 1 is active as long as TIMx\_CNT<TIMx\_CCR1 else inactive. In downcounting, channel 1 is inactive (OC1REF='0') as long as TIMx\_CNT>TIMx\_CCR1 else active (OC1REF='1').

0111: PWM mode 2 - In upcounting, channel 1 is inactive as long as TIMx\_CNT<TIMx\_CCR1 else active. In downcounting, channel 1 is active as long as TIMx\_CNT>TIMx\_CCR1 else inactive.

1000: Retriggerable OPM mode 1 - In up-counting mode, the channel is active until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update. In down-counting mode, the channel is inactive until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update.

1001: Retriggerable OPM mode 2 - In up-counting mode, the channel is inactive until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes inactive again at the next update. In down-counting mode, the channel is active until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update.

1010: Reserved,

1011: Reserved,

1100: Combined PWM mode 1 - OC1REF has the same behavior as in PWM mode 1. OC1REFC is the logical OR between OC1REF and OC2REF.

1101: Combined PWM mode 2 - OC1REF has the same behavior as in PWM mode 2. OC1REFC is the logical AND between OC1REF and OC2REF.

1110: Asymmetric PWM mode 1 - OC1REF has the same behavior as in PWM mode 1. OC1REFC outputs OC1REF when the counter is counting up, OC2REF when it is counting down.

1111: Asymmetric PWM mode 2 - OC1REF has the same behavior as in PWM mode 2. OC1REFC outputs OC1REF when the counter is counting up, OC2REF when it is counting down.

*Note: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx\_BDTR register) and CC1S='00' (the channel is configured in output).*

*Note: In PWM mode, the OCREF level changes only when the result of the comparison changes or when the output compare mode switches from "frozen" mode to "PWM" mode.*

*Note: On channels having a complementary output, this bit field is preloaded. If the CCPC bit is set in the TIMx\_CR2 register then the OC1M active bits take the new value from the preloaded bits only when a COM event is generated.*

*Note: The OC1M[3] bit is not contiguous, located in bit 16.*

Bit 3 **OC1PE**: Output Compare 1 preload enable

0: Preload register on TIMx\_CCR1 disabled. TIMx\_CCR1 can be written at anytime, the new value is taken in account immediately.

1: Preload register on TIMx\_CCR1 enabled. Read/Write operations access the preload register. TIMx\_CCR1 preload value is loaded in the active register at each update event.

*Note: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx\_BDTR register) and CC1S='00' (the channel is configured in output).*

Bit 2 **OC1FE**: Output Compare 1 fast enable

This bit decreases the latency between a trigger event and a transition on the timer output. It must be used in one-pulse mode (OPM bit set in TIMx\_CR1 register), to have the output pulse starting as soon as possible after the starting trigger.

0: CC1 behaves normally depending on counter and CCR1 values even when the trigger is ON. The minimum delay to activate CC1 output when an edge occurs on the trigger input is 5 clock cycles.

1: An active edge on the trigger input acts like a compare match on CC1 output. Then, OC is set to the compare level independently from the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OCFE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 **CC1S[1:0]**: Capture/Compare 1 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC1 channel is configured as output

01: CC1 channel is configured as input, IC1 is mapped on TI1

10: CC1 channel is configured as input, IC1 is mapped on TI2

11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note: CC1S bits are writable only when the channel is OFF (CC1E = '0' in TIMx\_CCER).*

### 30.4.9 TIMx capture/compare mode register 2 (TIMx\_CCMR2)(x = 1, 8)

Address offset: 0x1C

Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (e.g. channel 1 in input capture mode and channel 2 in output compare mode).

**Input capture mode:**

|           |      |      |      |             |      |           |      |           |      |      |      |             |      |           |      |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:12 **IC4F[3:0]**: Input capture 4 filter  
Refer to IC1F[3:0] description.

Bits 11:10 **IC4PSC[1:0]**: Input capture 4 prescaler  
Refer to IC1PSC[1:0] description.

Bits 9:8 **CC4S[1:0]**: Capture/Compare 4 selection  
This bit-field defines the direction of the channel (input/output) as well as the used input.  
00: CC4 channel is configured as output  
01: CC4 channel is configured as input, IC4 is mapped on TI4  
10: CC4 channel is configured as input, IC4 is mapped on TI3  
11: CC4 channel is configured as input, IC4 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)  
*Note: CC4S bits are writable only when the channel is OFF (CC4E = '0' in TIMx\_CCER).*

Bits 7:4 **IC3F[3:0]**: Input capture 3 filter  
Refer to IC1F[3:0] description.

Bits 3:2 **IC3PSC[1:0]**: Input capture 3 prescaler  
Refer to IC1PSC[1:0] description.

Bits 1:0 **CC3S[1:0]**: Capture/compare 3 selection  
This bit-field defines the direction of the channel (input/output) as well as the used input.  
00: CC3 channel is configured as output  
01: CC3 channel is configured as input, IC3 is mapped on TI3  
10: CC3 channel is configured as input, IC3 is mapped on TI4  
11: CC3 channel is configured as input, IC3 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)  
*Note: CC3S bits are writable only when the channel is OFF (CC3E = '0' in TIMx\_CCER).*

### 30.4.10 TIMx capture/compare mode register 2 [alternate] (TIMx\_CCMR2)(x = 1, 8)

Address offset: 0x1C

Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (e.g. channel 1 in input capture mode and channel 2 in output compare mode).

#### Output compare mode

|           |           |      |      |           |           |           |         |           |           |      |      |           |           |           |         |

Bit 8 **CC3E**: Capture/Compare 3 output enable  
Refer to CC1E description

Bit 7 **CC2NP**: Capture/Compare 2 complementary output polarity  
Refer to CC1NP description

Bit 6 **CC2NE**: Capture/Compare 2 complementary output enable  
Refer to CC1NE description

Bit 5 **CC2P**: Capture/Compare 2 output polarity  
Refer to CC1P description

Bit 4 **CC2E**: Capture/Compare 2 output enable  
Refer to CC1E description

Bit 3 **CC1NP**: Capture/Compare 1 complementary output polarity

**CC1 channel configured as output:**

0: OC1N active high.

1: OC1N active low.

**CC1 channel configured as input:**

This bit is used in conjunction with CC1P to define the polarity of TI1FP1 and TI2FP1. Refer to CC1P description.

*Note: This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx\_BDTR register) and CC1S="00" (channel configured as output).*

*On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx\_CR2 register then the CC1NP active bit takes the new value from the preloaded bit only when a Commutation event is generated.*

Bit 2 **CC1NE**: Capture/Compare 1 complementary output enable

0: Off - OC1N is not active. OC1N level is then function of MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.

1: On - OC1N signal is output on the corresponding output pin depending on MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.

*On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx\_CR2 register then the CC1NE active bit takes the new value from the preloaded bit only when a Commutation event is generated.*

Bit 1 **CC1P**: Capture/Compare 1 output polarity

0: OC1 active high (output mode) / Edge sensitivity selection (input mode, see below)

1: OC1 active low (output mode) / Edge sensitivity selection (input mode, see below)

When CC1 channel is configured as input, both CC1NP/CC1P bits select the active polarity of TI1FP1 and TI2FP1 for trigger or capture operations.

CC1NP=0, CC1P=0: non-inverted/rising edge. The circuit is sensitive to TIxFP1 rising edge (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger operation in gated mode or encoder mode).

CC1NP=0, CC1P=1: inverted/falling edge. The circuit is sensitive to TIxFP1 falling edge (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is inverted (trigger operation in gated mode or encoder mode).

CC1NP=1, CC1P=1: non-inverted/both edges/ The circuit is sensitive to both TIxFP1 rising and falling edges (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger operation in gated mode). This configuration must not be used in encoder mode.

CC1NP=1, CC1P=0: The configuration is reserved, it must not be used.

*Note: This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx\_BDTR register).*

*On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx\_CR2 register then the CC1P active bit takes the new value from the preloaded bit only when a Commutation event is generated.*

Bit 0 **CC1E**: Capture/Compare 1 output enable

0: Capture mode disabled / OC1 is not active (see below)

1: Capture mode enabled / OC1 signal is output on the corresponding output pin

**When CC1 channel is configured as output**, the OC1 level depends on MOE, OSS1, OSSR, OIS1, OIS1N and CC1NE bits, regardless of the CC1E bits state. Refer to [Table 199](#) for details.

*Note: On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx\_CR2 register then the CC1E active bit takes the new value from the preloaded bit only when a Commutation event is generated.*

**Table 199. Output control bits for complementary OCx and OCxN channels with break feature**

| Control bits |          |          |          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Output states <sup>(1)</sup>                                     |                                                              |

Bit 31 **UIFCPY**: UIF copy

This bit is a read-only copy of the UIF bit of the TIMx\_ISR register. If the UIFREMAP bit in the TIMxCR1 is reset, bit 31 is reserved and read at 0.

Bits 30:16 Reserved, must be kept at reset value.

Bits 15:0 **CNT[15:0]**: Counter value**30.4.13 TIMx prescaler (TIMx\_PSC)(x = 1, 8)**

Address offset: 0x28

Reset value: 0x0000

|           |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|-----------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| 15        | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
| PSC[15:0] |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
| r/w       | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w |

Bits 15:0 **PSC[15:0]**: Prescaler value

The counter clock frequency (CK\_CNT) is equal to  $f_{CK\_PSC} / (PSC[15:0] + 1)$ .

PSC contains the value to be loaded in the active prescaler register at each update event (including when the counter is cleared through UG bit of TIMx\_EGR register or through trigger controller when configured in “reset mode”).

**30.4.14 TIMx auto-reload register (TIMx\_ARR)(x = 1, 8)**

Address offset: 0x2C

Reset value: 0xFFFF

|           |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|-----------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| 15        | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
| ARR[15:0] |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
| r/w       | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w |

Bits 15:0 **ARR[15:0]**: Auto-reload value

ARR is the value to be loaded in the actual auto-reload register.

Refer to the [Section 30.3.1: Time-base unit on page 898](#) for more details about ARR update and behavior.

The counter is blocked while the auto-reload value is null.

### 30.4.15 TIMx repetition counter register (TIMx\_RCR)(x = 1, 8)

Address offset: 0x30

Reset value: 0x0000

|           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 15        | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| REP[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw        | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 15:0 **REP[15:0]**: Repetition counter value

These bits allow the user to set-up the update rate of the compare registers (i.e. periodic transfers from preload to active registers) when preload registers are enable, as well as the update interrupt generation rate, if this interrupt is enable.

Each time the REP\_CNT related downcounter reaches zero, an update event is generated and it restarts counting from REP value. As REP\_CNT is reloaded with REP value only at the repetition update event U\_RC, any write to the TIMx\_RCR register is not taken in account until the next repetition update event.

It means in PWM mode (REP+1) corresponds to:  
the number of PWM periods in edge-aligned mode  
the number of half PWM period in center-aligned mode.

### 30.4.16 TIMx capture/compare register 1 (TIMx\_CCR1)(x = 1, 8)

Address offset: 0x34

Reset value: 0x0000

|            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| CCR1[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw         | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 15:0 **CCR1[15:0]**: Capture/Compare 1 value

**If channel CC1 is configured as output:** CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIMx\_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx\_CNT and signaled on OC1 output.

**If channel CC1 is configured as input:** CR1 is the counter value transferred by the last input capture 1 event (IC1). The TIMx\_CCR1 register is read-only and cannot be programmed.

### 30.4.17 TIMx capture/compare register 2 (TIMx\_CCR2)(x = 1, 8)

Address offset: 0x38

Reset value: 0x0000

|            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| CCR2[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw         | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 15:0 **CCR2[15:0]**: Capture/Compare 2 value

**If channel CC2 is configured as output:** CCR2 is the value to be loaded in the actual capture/compare 2 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIMx\_CCMR1 register (bit OC2PE). Else the preload value is copied in the active capture/compare 2 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx\_CNT and signaled on OC2 output.

**If channel CC2 is configured as input:** CCR2 is the counter value transferred by the last input capture 2 event (IC2). The TIMx\_CCR2 register is read-only and cannot be programmed.

### 30.4.18 TIMx capture/compare register 3 (TIMx\_CCR3)(x = 1, 8)

Address offset: 0x3C

Reset value: 0x0000

|            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| CCR3[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw         | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 15:0 **CCR3[15:0]**: Capture/Compare value

**If channel CC3 is configured as output:** CCR3 is the value to be loaded in the actual capture/compare 3 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIMx\_CCMR2 register (bit OC3PE). Else the preload value is copied in the active capture/compare 3 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx\_CNT and signalled on OC3 output.

**If channel CC3 is configured as input:** CCR3 is the counter value transferred by the last input capture 3 event (IC3). The TIMx\_CCR3 register is read-only and cannot be programmed.

### 30.4.19 TIMx capture/compare register 4 (TIMx\_CCR4)(x = 1, 8)

Address offset: 0x40

Reset value: 0x0000

|            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| CCR4[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw         | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 15:0 **CCR4[15:0]**: Capture/Compare value

**If channel CC4 is configured as output:** CCR4 is the value to be loaded in the actual capture/compare 4 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIMx\_CCMR2 register (bit OC4PE). Else the preload value is copied in the active capture/compare 4 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx\_CNT and signalled on OC4 output.

**If channel CC4 is configured as input:** CCR4 is the counter value transferred by the last input capture 4 event (IC4). The TIMx\_CCR4 register is read-only and cannot be programmed.

### 30.4.20 TIMx break and dead-time register (TIMx\_BDTR)(x = 1, 8)

Address offset: 0x44

Reset value: 0x0000 0000

|      |      |      |      |      |      |           |      |           |    |    |    |          |    |    |    |
|------|------|------|------|------|------|-----------|------|-----------|----|----|----|----------|----|----|----|
| 31   | 30   | 29   | 28   | 27   | 26   | 25        | 24   | 23        | 22 | 21 | 20 | 19       | 18 | 17 | 16 |
| Res. | Res. | Res. | Res. | Res. | Res. | BK2P      | BK2E | BK2F[3:0] |    |    |    | BKF[3:0] |    |    |    |
|      |      |      |      |      |      | rw        | rw   | rw        | rw | rw | rw | rw       | rw | rw | rw |
| 15   | 14   | 13   | 12   | 11   | 10   | 9         | 8    | 7         | 6  | 5  | 4  | 3        | 2  | 1  | 0  |
| MOE  | AOE  | BKP  | BKE  | OSSR | OSSI | LOCK[1:0] |      | DTG[7:0]  |    |    |    |          |    |    |    |
| rw   | rw   | rw   | rw   | rw   | rw   | rw        | rw   | rw        | rw | rw | rw | rw       | rw | rw | rw |

**Note:** As the bits BK2P, BK2E, BK2F[3:0], BKF[3:0], AOE, BKP, BKE, OSSI, OSSR and DTG[7:0] can be write-locked depending on the LOCK configuration, it can be necessary to configure all of them during the first write access to the TIMx\_BDTR register.

Bits 31:26 Reserved, must be kept at reset value.

Bit 25 **BK2P**: Break 2 polarity

0: Break input BRK2 is active low

1: Break input BRK2 is active high

**Note:** This bit cannot be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).

**Note:** Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 24 **BK2E**: Break 2 enable

This bit enables the complete break 2 protection (including all sources connected to bk\_acth and BKIN sources, as per [Figure 267: Break and Break2 circuitry overview](#)).

0: Break2 function disabled

1: Break2 function enabled

*Note: The BKIN2 must only be used with OSSR = OSSI = 1.*

*Note: This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

*Note: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.*

Bits 23:20 **BK2F[3:0]**: Break 2 filter

This bit-field defines the frequency used to sample BRK2 input and the length of the digital filter applied to BRK2. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000: No filter, BRK2 acts asynchronously

0001:  $f_{\text{SAMPLING}} = f_{\text{CK\_INT}}$ , N=2

0010:  $f_{\text{SAMPLING}} = f_{\text{CK\_INT}}$ , N=4

0011:  $f_{\text{SAMPLING}} = f_{\text{CK\_INT}}$ , N=8

0100:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/2$ , N=6

0101:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/2$ , N=8

0110:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/4$ , N=6

0111:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/4$ , N=8

1000:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/8$ , N=6

1001:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/8$ , N=8

1010:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/16$ , N=5

1011:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/16$ , N=6

1100:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/16$ , N=8

1101:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/32$ , N=5

1110:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/32$ , N=6

1111:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/32$ , N=8

*Note: This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

Bits 19:16 **BKF[3:0]**: Break filter

This bit-field defines the frequency used to sample BRK input and the length of the digital filter applied to BRK. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000: No filter, BRK acts asynchronously

0001:  $f_{\text{SAMPLING}} = f_{\text{CK\_INT}}$ , N=2

0010:  $f_{\text{SAMPLING}} = f_{\text{CK\_INT}}$ , N=4

0011:  $f_{\text{SAMPLING}} = f_{\text{CK\_INT}}$ , N=8

0100:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/2$ , N=6

0101:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/2$ , N=8

0110:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/4$ , N=6

0111:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/4$ , N=8

1000:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/8$ , N=6

1001:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/8$ , N=8

1010:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/16$ , N=5

1011:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/16$ , N=6

1100:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/16$ , N=8

1101:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/32$ , N=5

1110:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/32$ , N=6

1111:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/32$ , N=8

*Note: This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

Bit 15 **MOE**: Main output enable

This bit is cleared asynchronously by hardware as soon as one of the break inputs is active (BRK or BRK2). It is set by software or automatically depending on the AOE bit. It is acting only on the channels which are configured in output.

0: In response to a break 2 event. OC and OCN outputs are disabled

In response to a break event or if MOE is written to 0: OC and OCN outputs are disabled or forced to idle state depending on the OSSR bit.

1: OC and OCN outputs are enabled if their respective enable bits are set (CCxE, CCxNE in TIMx\_CCER register).

See OC/OCN enable description for more details ([Section 30.4.11: TIMx capture/compare enable register \(TIMx\\_CCER\)\(x = 1, 8\)](#)).

Bit 14 **AOE**: Automatic output enable

0: MOE can be set only by software

1: MOE can be set by software or automatically at the next update event (if none of the break inputs BRK and BRK2 is active)

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

Bit 13 **BKP**: Break polarity

0: Break input BRK is active low

1: Break input BRK is active high

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

*Note: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.*

Bit 12 **BKE**: Break enable

This bit enables the complete break protection (including all sources connected to bk\_ach and BRK sources, as per [Figure 267: Break and Break2 circuitry overview](#)).

0: Break function disabled

1: Break function enabled

*Note: This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

*Note: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.*

Bit 11 **OSSR**: Off-state selection for Run mode

This bit is used when MOE=1 on channels having a complementary output which are configured as outputs. OSSR is not implemented if no complementary output is implemented in the timer.

See OC/OCN enable description for more details ([Section 30.4.11: TIMx capture/compare enable register \(TIMx\\_CCER\)\(x = 1, 8\)](#)).

0: When inactive, OC/OCN outputs are disabled (the timer releases the output control which is taken over by the GPIO logic, which forces a Hi-Z state).

1: When inactive, OC/OCN outputs are enabled with their inactive level as soon as CCxE=1 or CCxNE=1 (the output is still controlled by the timer).

*Note: This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx\_BDTR register).*

Bit 10 **OSSI**: Off-state selection for Idle mode

This bit is used when MOE=0 due to a break event or by a software write, on channels configured as outputs.

See OC/OCN enable description for more details ([Section 30.4.11: TIMx capture/compare enable register \(TIMx\\_CCER\)\(x = 1, 8\)](#)).

0: When inactive, OC/OCN outputs are disabled (the timer releases the output control which is taken over by the GPIO logic and which imposes a Hi-Z state).

1: When inactive, OC/OCN outputs are first forced with their inactive level then forced to their idle level after the deadtime. The timer maintains its control over the output.

*Note: This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx\_BDTR register).*

Bits 9:8 **LOCK[1:0]**: Lock configuration

These bits offer a write protection against software errors.

00: LOCK OFF - No bit is write protected.

01: LOCK Level 1 = DTG bits in TIMx\_BDTR register, OISx and OISxN bits in TIMx\_CR2 register and BKE/BKP/AOE bits in TIMx\_BDTR register can no longer be written.

10: LOCK Level 2 = LOCK Level 1 + CC Polarity bits (CCxP/CCxNP bits in TIMx\_CCER register, as long as the related channel is configured in output through the CCxS bits) as well as OSSR and OSSI bits can no longer be written.

11: LOCK Level 3 = LOCK Level 2 + CC Control bits (OCxM and OCxPE bits in TIMx\_CCMRx registers, as long as the related channel is configured in output through the CCxS bits) can no longer be written.

*Note: The LOCK bits can be written only once after the reset. Once the TIMx\_BDTR register has been written, their content is frozen until the next reset.*

Bits 7:0 **DTG[7:0]**: Dead-time generator setup

This bit-field defines the duration of the dead-time inserted between the complementary outputs. DT correspond to this duration.

DTG[7:5] = 0xx => DT = DTG[7:0] x  $t_{DTG}$  with  $t_{DTG} = t_{DTS}$ .

DTG[7:5] = 10x => DT = (64 + DTG[5:0]) x  $t_{DTG}$  with  $t_{DTG} = 2 \times t_{DTS}$ .

DTG[7:5] = 110 => DT = (32 + DTG[4:0]) x  $t_{DTG}$  with  $t_{DTG} = 8 \times t_{DTS}$ .

DTG[7:5] = 111 => DT = (32 + DTG[4:0]) x  $t_{DTG}$  with  $t_{DTG} = 16 \times t_{DTS}$ .

Example if  $t_{DTS} = 125$  ns (8 MHz), dead-time possible values are:

0 to 15875 ns by 125 ns steps,

16  $\mu$ s to 31750 ns by 250 ns steps,

32  $\mu$ s to 63  $\mu$ s by 1  $\mu$ s steps,

64  $\mu$ s to 126  $\mu$ s by 2  $\mu$ s steps

*Note: This bit-field can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx\_BDTR register).*

### 30.4.21 TIMx DMA control register (TIMx\_DCR)(x = 1, 8)

Address offset: 0x48

Reset value: 0x0000

| 15   | 14   | 13   | 12       | 11 | 10 | 9  | 8  | 7    | 6    | 5    | 4        | 3  | 2  | 1  | 0  |
|------|------|------|----------|----|----|----|----|------|------|------|----------|----|----|----|----|
| Res. | Res. | Res. | DBL[4:0] |    |    |    |    | Res. | Res. | Res. | DBA[4:0] |    |    |    |    |
|      |      |      | rw       | rw | rw | rw | rw |      |      |      | rw       | rw | rw | rw | rw |

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:8 **DBL[4:0]**: DMA burst length

This 5-bit vector defines the length of DMA transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIMx\_DMAR address), i.e. the number of transfers. Transfers can be in half-words or in bytes (see example below).

00000: 1 transfer

00001: 2 transfers

00010: 3 transfers

...

10001: 18 transfers

**Example:** Let us consider the following transfer: DBL = 7 bytes & DBA = TIMx\_CR1.

– If DBL = 7 bytes and DBA = TIMx\_CR1 represents the address of the byte to be transferred, the address of the transfer should be given by the following equation:

(TIMx\_CR1 address) + DBA + (DMA index), where DMA index = DBL

In this example, 7 bytes are added to (TIMx\_CR1 address) + DBA, which gives us the address from/to which the data is copied. In this case, the transfer is done to 7 registers starting from the following address: (TIMx\_CR1 address) + DBA

According to the configuration of the DMA Data Size, several cases may occur:

– If the DMA Data Size is configured in half-words, 16-bit data is transferred to each of the 7 registers.

– If the DMA Data Size is configured in bytes, the data is also transferred to 7 registers: the first register contains the first MSB byte, the second register, the first LSB byte and so on. So with the transfer Timer, one also has to specify the size of data transferred by DMA.

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **DBA[4:0]**: DMA base address

This 5-bits vector defines the base-address for DMA transfers (when read/write access are done through the TIMx\_DMAR address). DBA is defined as an offset starting from the address of the TIMx\_CR1 register.

Example:

00000: TIMx\_CR1,

00001: TIMx\_CR2,

00010: TIMx\_SMCR,

...

### 30.4.22 TIMx DMA address for full transfer (TIMx\_DMAR)(x = 1, 8)

Address offset: 0x4C

Reset value: 0x0000 0000

|             |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31          | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| DMAB[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw          | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
| 15          | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| DMAB[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw          | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:0 **DMAB[31:0]**: DMA register for burst accesses

A read or write operation to the DMAR register accesses the register located at the address (TIMx\_CR1 address) + (DBA + DMA index) x 4

where TIMx\_CR1 address is the address of the control register 1, DBA is the DMA base address configured in TIMx\_DCR register, DMA index is automatically controlled by the DMA transfer, and ranges from 0 to DBL (DBL configured in TIMx\_DCR).

### 30.4.23 TIM1 option register 1 (TIM1\_OR1)

Address offset: 0x50

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |      |      |         |              |      |                    |      |

|      |      |      |      |      |      |      |      |      |      |      |         |              |      |                    |      |
|      |      |      |      |      |      |      |      |      |      |      | rw      | rw           | rw   | rw                 | rw   |

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **TI1\_RMP**: Input Capture 1 remap

0: TIM1 input capture 1 is connected to I/O

1: TIM1 input capture 1 is connected to COMP1 output.

Bits 3:2 **ETR\_ADC3\_RMP[1:0]**: External trigger remap on ADC3 analog watchdog

00: TIM1\_ETR is not connected to ADC3 AWDx. This configuration must be selected when the ETR comes from the I/O.

01: TIM1\_ETR is connected to ADC3 AWD1.

10: TIM1\_ETR is connected to ADC3 AWD2.

11: TIM1\_ETR is connected to ADC3 AWD3.

*Note: ADC3 AWDx sources are 'ORed' with the TIM1\_ETR input signals. When ADC3 AWDx is used, it is necessary to make sure that the corresponding TIM1\_ETR input pin is not enabled in the alternate function controller. Refer to [Figure 245: TIM1 ETR input circuitry](#).*

Bits 1:0 **ETR\_ADC1\_RMP[1:0]**: External trigger remap on ADC1 analog watchdog

00 : TIM1\_ETR is not connected to ADC1 AWDx. This configuration must be selected when the ETR comes from the I/O.

01 : TIM1\_ETR is connected to ADC1 AWD1.

10 : TIM1\_ETR is connected to ADC1 AWD2.

11 : TIM1\_ETR is connected to ADC1 AWD3.

*Note: ADC1 AWDx sources are 'ORed' with the TIM1\_ETR input signals. When ADC1 AWDx is used, it is necessary to make sure that the corresponding TIM1\_ETR input pin is not enabled in the alternate function controller. Refer to [Figure 245: TIM1 ETR input circuitry](#).*

### 30.4.24 TIM8 option register 1 (TIM8\_OR1)

Distortion on Channel 3 output:

0: No effect of OC5REF on OC3REFC

1: OC3REFC is the logical AND of OC3REFC and OC5REF

This bit can either have immediate effect or be preloaded and taken into account after an update event (if preload feature is selected in TIMxCCMR2).

*Note: it is also possible to apply this distortion on combined PWM signals.*Bit 30 **GC5C2**: Group Channel 5 and Channel 2

Distortion on Channel 2 output:

0: No effect of OC5REF on OC2REFC

1: OC2REFC is the logical AND of OC2REFC and OC5REF

This bit can either have immediate effect or be preloaded and taken into account after an update event (if preload feature is selected in TIMxCCMR1).

*Note: it is also possible to apply this distortion on combined PWM signals.*Bit 29 **GC5C1**: Group Channel 5 and Channel 1

Distortion on Channel 1 output:

0: No effect of OC5REF on OC1REFC5

1: OC1REFC is the logical AND of OC1REFC and OC5REF

This bit can either have immediate effect or be preloaded and taken into account after an update event (if preload feature is selected in TIMxCCMR1).

*Note: it is also possible to apply this distortion on combined PWM signals.*

Bits 28:16 Reserved, must be kept at reset value.

Bits 15:0 **CCR5[15:0]**: Capture/Compare 5 value

CCR5 is the value to be loaded in the actual capture/compare 5 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIMx\_CCMR3 register (bit OC5PE). Else the preload value is copied in the active capture/compare 5 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx\_CNT and signaled on OC5 output.

**30.4.27 TIMx capture/compare register 6 (TIMx\_CCR6)(x = 1, 8)**

Address offset: 0x5C

Reset value: 0x0000

| 15         | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |

Bits 15:0 **CCR6[15:0]**: Capture/Compare 6 value

CCR6 is the value to be loaded in the actual capture/compare 6 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIMx\_CCMR3 register (bit OC6PE). Else the preload value is copied in the active capture/compare 6 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx\_CNT and signaled on OC6 output.

### 30.4.28 TIM1 option register 2 (TIM1\_OR2)

Address offset: 0x60

Reset value: 0x0000 0001

Bits 31:17 Reserved, must be kept at reset value.

Bits 16:14 **ETRSEL[2:0]**: ETR source selection

These bits select the ETR input source.

000: TIM1\_ETR source is selected with the ETR\_ADC3\_RMP and ETR\_ADC1\_RMP bitfield in TIM1\_OR1 register

001: COMP1 output connected to ETR input

010: COMP2 output connected to ETR input

Others: Reserved

Note: These bits can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).

Bits 13:12 Reserved, must be kept at reset value.

Bit 11 **BKCOMP2P**: BRK COMP2 input polarity

This bit selects the COMP2 input sensitivity. It must be programmed together with the BKP polarity bit.

0: COMP2 input polarity is not inverted (active low if BKP=0, active high if BKP=1)

1: COMP2 input polarity is inverted (active high if BKP=0, active low if BKP=1)

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).

Bit 10 **BKCOMP1P**: BRK COMP1 input polarity

This bit selects the COMP1 input sensitivity. It must be programmed together with the BKP polarity bit.

0: COMP1 input polarity is not inverted (active low if BKP=0, active high if BKP=1)

1: COMP1 input polarity is inverted (active high if BKP=0, active low if BKP=1)

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).

Bit 9 **BKINP**: BRK BKIN input polarity

This bit selects the BKIN alternate function input sensitivity. It must be programmed together with the BKP polarity bit.

0: BKIN input polarity is not inverted (active low if BKP=0, active high if BKP=1)

1: BKIN input polarity is inverted (active high if BKP=0, active low if BKP=1)

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).

Bit 8 **BKDF1BK0E**: BRK dfsdm1\_break[0] enable

This bit enables the dfsdm1\_break[0] for the timer's BRK input. dfsdm1\_break[0] output is 'ORed' with the other BRK sources.

0: dfsdm1\_break[0] input disabled

1: dfsdm1\_break[0] input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

Bits 7:3 Reserved, must be kept at reset value.

Bit 2 **BKCOMP2E**: BRK COMP2 enable

This bit enables the COMP2 for the timer's BRK input. COMP2 output is 'ORed' with the other BRK sources.

0: COMP2 input disabled

1: COMP2 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

Bit 1 **BKCOMP1E**: BRK COMP1 enable

This bit enables the COMP1 for the timer's BRK input. COMP1 output is 'ORed' with the other BRK sources.

0: COMP1 input disabled

1: COMP1 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

Bit 0 **BKINE**: BRK BKIN input enable

This bit enables the BKIN alternate function input for the timer's BRK input. BKIN input is 'ORed' with the other BRK sources.

0: BKIN input disabled

1: BKIN input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

*Note: Refer to [Figure 245: TIM1 ETR input circuitry](#) and to [Figure 267: Break and Break2 circuitry overview](#).*

### 30.4.29 TIM1 option register 3 (TIM1\_OR3)

Bits 31:12 Reserved, must be kept at reset value.

**Bit 11 BK2CMP2P:** BRK2 COMP2 input polarity

This bit selects the COMP2 input sensitivity. It must be programmed together with the BK2P polarity bit.

0: COMP2 input polarity is not inverted (active low if BK2P=0, active high if BK2P=1)

1: COMP2 input polarity is inverted (active high if BK2P=0, active low if BK2P=1)

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

**Bit 10 BK2CMP1P:** BRK2 COMP1 input polarity

This bit selects the COMP1 input sensitivity. It must be programmed together with the BK2P polarity bit.

0: COMP1 input polarity is not inverted (active low if BK2P=0, active high if BK2P=1)

1: COMP1 input polarity is inverted (active high if BK2P=0, active low if BK2P=1)

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

**Bit 9 BK2INP:** BRK2 BKIN2 input polarity

This bit selects the BKIN2 alternate function input sensitivity. It must be programmed together with the BK2P polarity bit.

0: BKIN2 input polarity is not inverted (active low if BK2P=0, active high if BK2P=1)

1: BKIN2 input polarity is inverted (active high if BK2P=0, active low if BK2P=1)

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

**Bit 8 BK2DF1BK1E:** BRK2 dfsdm1\_break[1] enable

This bit enables the dfsdm1\_break[1] for the timer's BRK2 input. dfsdm1\_break[1] output is 'ORed' with the other BRK2 sources.

0: dfsdm1\_break[1] input disabled

1: dfsdm1\_break[1] input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

Bits 7:3 Reserved, must be kept at reset value.

**Bit 2 BK2CMP2E:** BRK2 COMP2 enable

This bit enables the COMP2 for the timer's BRK2 input. COMP2 output is 'ORed' with the other BRK2 sources.

0: COMP2 input disabled

1: COMP2 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

**Bit 1 BK2CMP1E:** BRK2 COMP1 enable

This bit enables the COMP1 for the timer's BRK2 input. COMP1 output is 'ORed' with the other BRK2 sources.

0: COMP1 input disabled

1: COMP1 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

Bit 0 **BK2INE**: BRK2 BKIN input enable

This bit enables the BKIN2 alternate function input for the timer's BRK2 input. BKIN2 input is 'ORed' with the other BRK2 sources.

0: BKIN2 input disabled

1: BKIN2 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

*Note: Refer to [Figure 267: Break and Break2 circuitry overview](#).*

Bits 31:17 Reserved, must be kept at reset value.

Bits 16:14 **ETRSEL[2:0]**: ETR source selection

These bits select the ETR input source.

000: TIM8\_ETR is selected with the ETR\_ADC3\_RMP and ETR\_ADC2\_RMP bitfield in TIM8\_OR1 register

001: COMP1 output connected to ETR input

010: COMP2 output connected to ETR input

Others: Reserved

*Note: These bits can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

Bits 13:12 Reserved, must be kept at reset value.

Bit 11 **BKCMP2P**: BRK COMP2 input polarity

This bit selects the COMP2 input sensitivity. It must be programmed together with the BKP polarity bit.

0: COMP2 input polarity is not inverted (active low if BKP=0, active high if BKP=1)

1: COMP2 input polarity is inverted (active high if BKP=0, active low if BKP=1)

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

Bit 10 **BKCMP1P**: BRK COMP1 input polarity

This bit selects the COMP1 input sensitivity. It must be programmed together with the BKP polarity bit.

0: COMP1 input polarity is not inverted (active low if BKP=0, active high if BKP=1)

1: COMP1 input polarity is inverted (active high if BKP=0, active low if BKP=1)

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

**Bit 9 BKINP:** BRK BKIN input polarity

This bit selects the BKIN alternate function input sensitivity. It must be programmed together with the BKP polarity bit.

0: BKIN input polarity is not inverted (active low if BKP=0, active high if BKP=1)

1: BKIN input polarity is inverted (active high if BKP=0, active low if BKP=1)

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

**Bit 8 BKDF1BK2E:** BRK dfsdm1\_break[2] enable

This bit enables the dfsdm1\_break[2] for the timer's BRK input. dfsdm1\_break[2] output is 'ORed' with the other BRK sources.

0: dfsdm1\_break[2] input disabled

1: dfsdm1\_break[2] input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

Bits 7:3 Reserved, must be kept at reset value.

**Bit 2 BKCMP2E:** BRK COMP2 enable

This bit enables the COMP2 for the timer's BRK input. COMP2 output is 'ORed' with the other BRK sources.

0: COMP2 input disabled

1: COMP2 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

**Bit 1 BKCMP1E:** BRK COMP1 enable

This bit enables the COMP1 for the timer's BRK input. COMP1 output is 'ORed' with the other BRK sources.

0: COMP1 input disabled

1: COMP1 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

**Bit 0 BKINE:** BRK BKIN input enable

This bit enables the BKIN alternate function input for the timer's BRK input. BKIN input is 'ORed' with the other BRK sources.

0: BKIN input disabled

1: BKIN input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

*Note:* Refer to [Figure 246: TIM8 ETR input circuitry](#) and to [Figure 267: Break and Break2 circuitry overview](#).

Bits 31:12 Reserved, must be kept at reset value.

**Bit 11 BK2CMP2P:** BRK2 COMP2 input polarity

This bit selects the COMP2 input sensitivity. It must be programmed together with the BK2P polarity bit.

0: COMP2 input polarity is not inverted (active low if BK2P=0, active high if BK2P=1)

1: COMP2 input polarity is inverted (active high if BK2P=0, active low if BK2P=1)

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

**Bit 10 BK2CMP1P:** BRK2 COMP1 input polarity

This bit selects the COMP1 input sensitivity. It must be programmed together with the BK2P polarity bit.

0: COMP1 input polarity is not inverted (active low if BK2P=0, active high if BK2P=1)

1: COMP1 input polarity is inverted (active high if BK2P=0, active low if BK2P=1)

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

**Bit 9 BK2INP:** BRK2 BKIN2 input polarity

This bit selects the BKIN2 alternate function input sensitivity. It must be programmed together with the BK2P polarity bit.

0: BKIN2 input polarity is not inverted (active low if BK2P=0, active high if BK2P=1)

1: BKIN2 input polarity is inverted (active high if BK2P=0, active low if BK2P=1)

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

**Bit 8 BK2DF1BK3E:** BRK2 dfsdm1\_break[3] enable

This bit enables the dfsdm1\_break[3] for the timer's BRK2 input. dfsdm1\_break[3] output is 'ORed' with the other BRK2 sources.

0: dfsdm1\_break[3] input disabled

1: dfsdm1\_break[3] input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

Bits 7:3 Reserved, must be kept at reset value.

**Bit 2 BK2CMP2E:** BRK2 COMP2 enable

This bit enables the COMP2 for the timer's BRK2 input. COMP2 output is 'ORed' with the other BRK2 sources.

0: COMP2 input disabled

1: COMP2 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

**Bit 1 BK2CMP1E:** BRK2 COMP1 enable

This bit enables the COMP1 for the timer's BRK2 input. COMP1 output is 'ORed' with the other BRK2 sources.

0: COMP1 input disabled

1: COMP1 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

**Bit 0 BK2INE:** BRK2 BKIN input enable

This bit enables the BKIN2 alternate function input for the timer's BRK2 input. BKIN2 input is 'ORed' with the other BRK2 sources.

0: BKIN2 input disabled

1: BKIN2 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

*Note:* Refer to [Figure 267: Break and Break2 circuitry overview](#).

## 30.4.32 TIM1 register map

TIM1 registers are mapped as 16-bit addressable registers as described in the table below:

Table 200. TIM1 register map and reset values

| Offset | Register name                     | 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24      | 23        | 22   | 21   | 20   | 19   | 18   | 17   | 16      | 15        | 14         | 13          | 12            | 11          | 10        | 9           | 8    | 7             | 6           | 5     | 4        | 3     | 2           | 1     | 0    |      |
|--------|-----------------------------------|------|------|------|------|------|------|------|---------|-----------|------|------|------|------|------|------|---------|-----------|------------|-------------|---------------|-------------|-----------|-------------|------|---------------|-------------|-------|----------|-------|-------------|-------|------|------|

Refer to [Section 2.2 on page 75](#) for the register boundary addresses.

### 30.4.33 TIM8 register map

TIM8 registers are mapped as 16-bit addressable registers as described in the table below:

Table 201. TIM8 register map and reset values

| Offset | Register name | 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23        | 22   | 21   | 20   | 19   | 18   | 17     | 16    | 15   | 14         | 13    | 12       | 11      | 10    | 9         | 8       | 7         | 6         | 5     | 4     | 3     | 2     | 1     | 0   |

Refer to [Section 2.2 on page 75](#) for the register boundary addresses.

## 31 General-purpose timers (TIM2/TIM3/TIM4/TIM5)

### 31.1 TIM2/TIM3/TIM4/TIM5 introduction

The general-purpose timers consist of a 16-bit/32-bit auto-reload counter driven by a programmable prescaler.

They may be used for a variety of purposes, including measuring the pulse lengths of input signals (*input capture*) or generating output waveforms (*output compare and PWM*).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The timers are completely independent, and do not share any resources. They can be synchronized together as described in [Section 31.3.19: Timer synchronization](#).

### 31.2 TIM2/TIM3/TIM4/TIM5 main features

General-purpose TIMx timer features include:

- 16-bit (TIM3, TIM4) or 32-bit (TIM2 and TIM5) up, down, up/down auto-reload counter.
- 16-bit programmable prescaler used to divide (also “on the fly”) the counter clock frequency by any factor between 1 and 65535.
- Up to 4 independent channels for:
  - Input capture
  - Output compare
  - PWM generation (Edge- and Center-aligned modes)
  - One-pulse mode output
- Synchronization circuit to control the timer with external signals and to interconnect several timers.
- Interrupt/DMA generation on the following events:
  - Update: counter overflow/underflow, counter initialization (by software or internal/external trigger)
  - Trigger event (counter start, stop, initialization or count by internal/external trigger)
  - Input capture
  - Output compare
- Supports incremental (quadrature) encoder and hall-sensor circuitry for positioning purposes
- Trigger input for external clock or cycle-by-cycle current management

Figure 284. General-purpose timer block diagram

## 31.3 TIM2/TIM3/TIM4/TIM5 functional description

### 31.3.1 Time-base unit

The main block of the programmable timer is a 16-bit/32-bit counter with its related auto-reload register. The counter can count up, down or both up and down. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:

- Counter Register (TIMx\_CNT)
- Prescaler Register (TIMx\_PSC)
- Auto-Reload Register (TIMx\_ARR)

The auto-reload register is preloaded. Writing to or reading from the auto-reload register accesses the preload register. The content of the preload register are transferred into the shadow register permanently or at each update event (UEV), depending on the auto-reload preload enable bit (ARPE) in TIMx\_CR1 register. The update event is sent when the counter reaches the overflow (or underflow when downcounting) and if the UDIS bit equals 0 in the TIMx\_CR1 register. It can also be generated by software. The generation of the update event is described in detail for each configuration.

The counter is clocked by the prescaler output CK\_CNT, which is enabled only when the counter enable bit (CEN) in TIMx\_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

Note that the actual counter enable signal CNT\_EN is set 1 clock cycle after CEN.

#### Prescaler description

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit/32-bit register (in the TIMx\_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

[Figure 285](#) and [Figure 286](#) give some examples of the counter behavior when the prescaler ratio is changed on the fly:

Figure 285. Counter timing diagram with prescaler division change from 1 to 2

Figure 286. Counter timing diagram with prescaler division change from 1 to 4

### 31.3.2 Counter modes

#### Upcounting mode

In upcounting mode, the counter counts from 0 to the auto-reload value (content of the TIMx\_ARR register), then restarts from 0 and generates a counter overflow event.

An Update event can be generated at each counter overflow or by setting the UG bit in the TIMx\_EGR register (by software or by using the slave mode controller).

The UEV event can be disabled by software by setting the UDIS bit in TIMx\_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIMx\_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx\_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (content of the TIMx\_PSC register)
- The auto-reload shadow register is updated with the preload value (TIMx\_ARR)

The following figures show some examples of the counter behavior for different clock frequencies when TIMx\_ARR=0x36.

**Figure 287. Counter timing diagram, internal clock divided by 1**

Figure 288. Counter timing diagram, internal clock divided by 2

Figure 289. Counter timing diagram, internal clock divided by 4

Figure 290. Counter timing diagram, internal clock divided by N

Figure 291. Counter timing diagram, Update event when ARPE=0 (TIMx\_ARR not preloaded)

**Figure 292. Counter timing diagram, Update event when ARPE=1 (TIMx\_ARR preloaded)**

### Downcounting mode

In downcounting mode, the counter counts from the auto-reload value (content of the TIMx\_ARR register) down to 0, then restarts from the auto-reload value and generates a counter underflow event.

An Update event can be generated at each counter underflow or by setting the UG bit in the TIMx\_EGR register (by software or by using the slave mode controller)

The UEV update event can be disabled by software by setting the UDIS bit in TIMx\_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until UDIS bit has been written to 0. However, the counter restarts from the current auto-reload value, whereas the counter of the prescaler restarts from 0 (but the prescale rate doesn't change).

In addition, if the URS bit (update request selection) in TIMx\_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx\_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (content of the TIMx\_PSC register).
- The auto-reload active register is updated with the preload value (content of the TIMx\_ARR register). Note that the auto-reload is updated before the counter is reloaded, so that the next period is the expected one.

The following figures show some examples of the counter behavior for different clock frequencies when TIMx\_ARR=0x36.

Figure 293. Counter timing diagram, internal clock divided by 1

Figure 294. Counter timing diagram, internal clock divided by 2

Figure 295. Counter timing diagram, internal clock divided by 4

Figure 296. Counter timing diagram, internal clock divided by N

Figure 297. Counter timing diagram, Update event

### Center-aligned mode (up/down counting)

In center-aligned mode, the counter counts from 0 to the auto-reload value (content of the TIMx\_ARR register) – 1, generates a counter overflow event, then counts from the auto-reload value down to 1 and generates a counter underflow event. Then it restarts counting from 0.

Center-aligned mode is active when the CMS bits in TIMx\_CR1 register are not equal to '00'. The Output compare interrupt flag of channels configured in output is set when: the counter counts down (Center aligned mode 1, CMS = "01"), the counter counts up (Center aligned mode 2, CMS = "10") the counter counts up and down (Center aligned mode 3, CMS = "11").

In this mode, the direction bit (DIR from TIMx\_CR1 register) cannot be written. It is updated by hardware and gives the current direction of the counter.

The update event can be generated at each counter overflow and at each counter underflow or by setting the UG bit in the TIMx\_EGR register (by software or by using the slave mode controller) also generates an update event. In this case, the counter restarts counting from 0, as well as the counter of the prescaler.

The UEV update event can be disabled by software by setting the UDIS bit in TIMx\_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter continues counting up and down, based on the current auto-reload value.

In addition, if the URS bit (update request selection) in TIMx\_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or

DMA request is sent). This is to avoid generating both update and capture interrupt when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx\_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (content of the TIMx\_PSC register).
- The auto-reload active register is updated with the preload value (content of the TIMx\_ARR register). Note that if the update source is a counter overflow, the auto-reload is updated before the counter is reloaded, so that the next period is the expected one (the counter is loaded with the new value).

The following figures show some examples of the counter behavior for different clock frequencies.

**Figure 298. Counter timing diagram, internal clock divided by 1, TIMx\_ARR=0x6**

1. Here, center-aligned mode 1 is used (for more details refer to [Section 31.4.1: TIMx control register 1 \(TIMx\\_CR1\)\(x = 2 to 5\) on page 1047](#)).

Figure 302. Counter timing diagram, Update event with ARPE=1 (counter underflow)

**Figure 303. Counter timing diagram, Update event with ARPE=1 (counter overflow)**

### 31.3.3 Clock selection

The counter clock can be provided by the following clock sources:

- Internal clock (CK\_INT)
- External clock mode1: external input pin (TIx)
- External clock mode2: external trigger input (ETR)
- Internal trigger inputs (ITRx): using one timer as prescaler for another timer, for example, Timer X can be configured to act as a prescaler for Timer Y. Refer to : [Using one timer as prescaler for another timer on page 1041](#) for more details.

#### Internal clock source (CK\_INT)

If the slave mode controller is disabled (SMS=000 in the TIMx\_SMCR register), then the CEN, DIR (in the TIMx\_CR1 register) and UG bits (in the TIMx\_EGR register) are actual control bits and can be changed only by software (except UG which remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock CK\_INT.

[Figure 304](#) shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.

Figure 304. Control circuit in normal mode, internal clock divided by 1

External clock source mode 1

This mode is selected when SMS=111 in the TIMx\_SMCR register. The counter can count at each rising or falling edge on a selected input.

Figure 305. TI2 external clock connection example

For example, to configure the upcounter to count in response to a rising edge on the TI2 input, use the following procedure:

1. Configure channel 2 to detect rising edges on the TI2 input by writing CC2S= '01 in the TIMx\_CCMR1 register.
2. Configure the input filter duration by writing the IC2F[3:0] bits in the TIMx\_CCMR1 register (if no filter is needed, keep IC2F=0000).

*Note:* The capture prescaler is not used for triggering, so it does not need to be configured.

3. Select rising edge polarity by writing CC2P=0 and CC2NP=0 and CC2NP=0 in the TIMx\_CCER register.
4. Configure the timer in external clock mode 1 by writing SMS=111 in the TIMx\_SMCR register.
5. Select TI2 as the input source by writing TS=110 in the TIMx\_SMCR register.
6. Enable the counter by writing CEN=1 in the TIMx\_CR1 register.

When a rising edge occurs on TI2, the counter counts once and the TIF flag is set.

The delay between the rising edge on TI2 and the actual clock of the counter is due to the resynchronization circuit on TI2 input.

**Figure 306. Control circuit in external clock mode 1**

### External clock source mode 2

This mode is selected by writing ECE=1 in the TIMx\_SMCR register.

The counter can count at each rising or falling edge on the external trigger input ETR.

[Figure 307](#) gives an overview of the external trigger input block.

Figure 307. External trigger input block

For example, to configure the upcounter to count each 2 rising edges on ETR, use the following procedure:

1. As no filter is needed in this example, write ETF[3:0]=0000 in the TIMx\_SMCR register.
2. Set the prescaler by writing ETPS[1:0]=01 in the TIMx\_SMCR register
3. Select rising edge detection on the ETR pin by writing ETP=0 in the TIMx\_SMCR register
4. Enable external clock mode 2 by writing ECE=1 in the TIMx\_SMCR register.
5. Enable the counter by writing CEN=1 in the TIMx\_CR1 register.

The counter counts once each 2 ETR rising edges.

The delay between the rising edge on ETR and the actual clock of the counter is due to the resynchronization circuit on the ETRP signal. As a consequence, the maximum frequency which can be correctly captured by the counter is at most  $\frac{1}{4}$  of TIMxCLK frequency. When the ETRP signal is faster, the user should apply a division of the external signal by a proper ETPS prescaler setting.

Figure 308. Control circuit in external clock mode 2

### 31.3.4 Capture/Compare channels

Each Capture/Compare channel is built around a capture/compare register (including a shadow register), a input stage for capture (with digital filter, multiplexing and prescaler) and an output stage (with comparator and output control).

The following figure gives an overview of one Capture/Compare channel.

The input stage samples the corresponding TIx input to generate a filtered signal TIxF. Then, an edge detector with polarity selection generates a signal (TIxFPx) which can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (ICxPS).

Figure 309. Capture/Compare channel (example: channel 1 input stage)

The output stage generates an intermediate waveform which is then used for reference: OCxRef (active high). The polarity acts at the end of the chain.

Figure 310. Capture/Compare channel 1 main circuit

Figure 311. Output stage of Capture/Compare channel (channel 1)

The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register.

In capture mode, captures are actually done in the shadow register, which is copied into the preload register.

In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

### 31.3.5 Input capture mode

In Input capture mode, the Capture/Compare Registers (TIMx\_CCRx) are used to latch the value of the counter after a transition detected by the corresponding ICx signal. When a capture occurs, the corresponding CCxIF flag (TIMx\_SR register) is set and an interrupt or a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was already high, then the over-capture flag CCxOF (TIMx\_SR register) is set. CCxIF can be cleared by software by writing it to 0 or by reading the captured data stored in the TIMx\_CCRx register. CCxOF is cleared when it is written with 0.

The following example shows how to capture the counter value in TIMx\_CCR1 when TI1 input rises. To do this, use the following procedure:

1. Select the active input: TIMx\_CCR1 must be linked to the TI1 input, so write the CC1S bits to 01 in the TIMx\_CCMR1 register. As soon as CC1S becomes different from 00, the channel is configured in input and the TIMx\_CCR1 register becomes read-only.
2. Program the appropriate input filter duration in relation with the signal connected to the timer (when the input is one of the TIx (ICxF bits in the TIMx\_CCMRx register). Let's imagine that, when toggling, the input signal is not stable during at most 5 internal clock cycles. We must program a filter duration longer than these 5 clock cycles. We can validate a transition on TI1 when 8 consecutive samples with the new level have been

detected (sampled at  $f_{DTS}$  frequency). Then write IC1F bits to 0011 in the TIMx\_CCMR1 register.

3. Select the edge of the active transition on the TI1 channel by writing the CC1P and CC1NP and CC1NP bits to 000 in the TIMx\_CCER register (rising edge in this case).
4. Program the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to 00 in the TIMx\_CCMR1 register).
5. Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx\_CCER register.
6. If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx\_DIER register, and/or the DMA request by setting the CC1DE bit in the TIMx\_DIER register.

When an input capture occurs:

- The TIMx\_CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.
- A DMA request is generated depending on the CC1DE bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which could happen after reading the flag and before reading the data.

*Note:* IC interrupt and/or DMA requests can be generated by software by setting the corresponding CCxG bit in the TIMx\_EGR register.

### 31.3.6 PWM input mode

This mode is a particular case of input capture mode. The procedure is the same except:

- Two ICx signals are mapped on the same TIx input.
- These 2 ICx signals are active on edges with opposite polarity.
- One of the two TIxFP signals is selected as trigger input and the slave mode controller is configured in reset mode.

For example, one can measure the period (in TIMx\_CCR1 register) and the duty cycle (in TIMx\_CCR2 register) of the PWM applied on TI1 using the following procedure (depending on CK\_INT frequency and prescaler value):

1. Select the active input for TIMx\_CCR1: write the CC1S bits to 01 in the TIMx\_CCMR1 register (TI1 selected).
2. Select the active polarity for TI1FP1 (used both for capture in TIMx\_CCR1 and counter clear): write the CC1P to '0' and the CC1NP bit to '0' (active on rising edge).
3. Select the active input for TIMx\_CCR2: write the CC2S bits to 10 in the TIMx\_CCMR1 register (TI1 selected).
4. Select the active polarity for TI1FP2 (used for capture in TIMx\_CCR2): write the CC2P bit to '1' and the CC2NP bit to '0' (active on falling edge).
5. Select the valid trigger input: write the TS bits to 101 in the TIMx\_SMCR register (TI1FP1 selected).
6. Configure the slave mode controller in reset mode: write the SMS bits to 100 in the TIMx\_SMCR register.
7. Enable the captures: write the CC1E and CC2E bits to '1' in the TIMx\_CCER register.

**Figure 312. PWM input mode timing**

1. The PWM input mode can be used only with the TIMx\_CH1/TIMx\_CH2 signals due to the fact that only TI1FP1 and TI2FP2 are connected to the slave mode controller.

### 31.3.7 Forced output mode

In output mode (CCxS bits = 00 in the TIMx\_CCMRx register), each output compare signal (OCxREF and then OCx) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (ocxref/OCx) to its active level, one just needs to write 101 in the OCxM bits in the corresponding TIMx\_CCMRx register. Thus ocxref is forced high (OCxREF is always active high) and OCx get opposite value to CCxP polarity bit.

e.g.: CCxP=0 (OCx active high) => OCx is forced to high level.

ocxref signal can be forced low by writing the OCxM bits to 100 in the TIMx\_CCMRx register.

Anyway, the comparison between the TIMx\_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt and DMA requests can be sent accordingly. This is described in the Output Compare Mode section.

### 31.3.8 Output compare mode

This function is used to control an output waveform or indicating when a period of time has elapsed.

When a match is found between the capture/compare register and the counter, the output compare function:

- Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx\_CCMRx register) and the output polarity (CCxP bit in the TIMx\_CCER register). The output pin can keep its level (OCxM=000), be set active (OCxM=001), be set inactive (OCxM=010) or can toggle (OCxM=011) on match.
- Sets a flag in the interrupt status register (CCxIF bit in the TIMx\_SR register).
- Generates an interrupt if the corresponding interrupt mask is set (CCxIE bit in the TIMx\_DIER register).
- Sends a DMA request if the corresponding enable bit is set (CCxDE bit in the TIMx\_DIER register, CCDS bit in the TIMx\_CR2 register for the DMA request selection).

The TIMx\_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx\_CCMRx register.

In output compare mode, the update event UEV has no effect on ocxref and OCx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One-pulse mode).

#### Procedure

1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx\_ARR and TIMx\_CCRx registers.
3. Set the CCxIE and/or CCxDE bits if an interrupt and/or a DMA request is to be generated.
4. Select the output mode. For example, one must write OCxM=011, OCxPE=0, CCxP=0 and CCxE=1 to toggle OCx output pin when CNT matches CCRx, CCRx preload is not used, OCx is enabled and active high.
5. Enable the counter by setting the CEN bit in the TIMx\_CR1 register.

The TIMx\_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE=0, else TIMx\_CCRx shadow register is updated only at the next update event UEV). An example is given in [Figure 313](#).

Figure 313. Output compare mode, toggle on OC1

### 31.3.9 PWM mode

Pulse width modulation mode permits to generate a signal with a frequency determined by the value of the TIMx\_ARR register and a duty cycle determined by the value of the TIMx\_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per OCx output) by writing 110 (PWM mode 1) or '111 (PWM mode 2) in the OCxM bits in the TIMx\_CCMRx register. The corresponding preload register must be enabled by setting the OCxPE bit in the TIMx\_CCMRx register, and eventually the auto-reload preload register (in upcounting or center-aligned modes) by setting the ARPE bit in the TIMx\_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, all registers must be initialized by setting the UG bit in the TIMx\_EGR register.

OCx polarity is software programmable using the CCxP bit in the TIMx\_CCER register. It can be programmed as active high or active low. OCx output is enabled by the CCxE bit in the TIMx\_CCER register. Refer to the TIMx\_CCERx register description for more details.

In PWM mode (1 or 2), TIMx\_CNT and TIMx\_CCRx are always compared to determine whether  $TIMx\_CCRx \leq TIMx\_CNT$  or  $TIMx\_CNT \leq TIMx\_CCRx$  (depending on the direction of the counter). However, to comply with the OCREF\_CLR functionality (OCREF can be cleared by an external event through the ETR signal until the next PWM period), the OCREF signal is asserted only:

- When the result of the comparison or
- When the output compare mode (OCxM bits in TIMx\_CCMRx register) switches from the "frozen" configuration (no comparison, OCxM='000) to one of the PWM modes (OCxM='110 or '111).

This forces the PWM by software while the timer is running.

The timer is able to generate PWM in edge-aligned mode or center-aligned mode depending on the CMS bits in the TIMx\_CR1 register.

### PWM edge-aligned mode

#### Upcounting configuration

Upcounting is active when the DIR bit in the TIMx\_CR1 register is low. Refer to [Upcounting mode on page 1005](#).

In the following example, we consider PWM mode 1. The reference PWM signal OCxREF is high as long as TIMx\_CNT < TIMx\_CCRx else it becomes low. If the compare value in TIMx\_CCRx is greater than the auto-reload value (in TIMx\_ARR) then OCxREF is held at '1'. If the compare value is 0 then OCxREF is held at '0'. [Figure 314](#) shows some edge-aligned PWM waveforms in an example where TIMx\_ARR=8.

**Figure 314. Edge-aligned PWM waveforms (ARR=8)**

#### Downcounting configuration

Downcounting is active when DIR bit in TIMx\_CR1 register is high. Refer to [Downcounting mode on page 1008](#).

In PWM mode 1, the reference signal ocxref is low as long as TIMx\_CNT > TIMx\_CCRx else it becomes high. If the compare value in TIMx\_CCRx is greater than the auto-reload value in TIMx\_ARR, then ocxref is held at 100%. PWM is not possible in this mode.

### PWM center-aligned mode

Center-aligned mode is active when the CMS bits in TIMx\_CR1 register are different from '00' (all the remaining configurations having the same effect on the ocxref/OCx signals). The

compare flag is set when the counter counts up, when it counts down or both when it counts up and down depending on the CMS bits configuration. The direction bit (DIR) in the TIMx\_CR1 register is updated by hardware and must not be changed by software. Refer to [Center-aligned mode \(up/down counting\) on page 1011](#).

Figure 315 shows some center-aligned PWM waveforms in an example where:

- TIMx\_ARR=8,
- PWM mode is the PWM mode 1,
- The flag is set when the counter counts down corresponding to the center-aligned mode 1 selected for CMS=01 in TIMx\_CR1 register.

**Figure 315. Center-aligned PWM waveforms (ARR=8)**

Hints on using center-aligned mode:

- When starting in center-aligned mode, the current up-down configuration is used. It means that the counter counts up or down depending on the value written in the DIR bit

- in the TIMx\_CR1 register. Moreover, the DIR and CMS bits must not be changed at the same time by the software.
- Writing to the counter while running in center-aligned mode is not recommended as it can lead to unexpected results. In particular:
    - The direction is not updated if a value greater than the auto-reload value is written in the counter (TIMx\_CNT > TIMx\_ARR). For example, if the counter was counting up, it continues to count up.
    - The direction is updated if 0 or the TIMx\_ARR value is written in the counter but no Update Event UEV is generated.
  - The safest way to use center-aligned mode is to generate an update by software (setting the UG bit in the TIMx\_EGR register) just before starting the counter and not to write the counter while it is running.

### 31.3.10 Asymmetric PWM mode

Asymmetric mode allows two center-aligned PWM signals to be generated with a programmable phase shift. While the frequency is determined by the value of the TIMx\_ARR register, the duty cycle and the phase-shift are determined by a pair of TIMx\_CCRx registers. One register controls the PWM during up-counting, the second during down-counting, so that PWM is adjusted every half PWM cycle:

- OC1REFC (or OC2REFC) is controlled by TIMx\_CCR1 and TIMx\_CCR2
- OC3REFC (or OC4REFC) is controlled by TIMx\_CCR3 and TIMx\_CCR4

Asymmetric PWM mode can be selected independently on two channels (one OCx output per pair of CCR registers) by writing '1110' (Asymmetric PWM mode 1) or '1111' (Asymmetric PWM mode 2) in the OCxM bits in the TIMx\_CCMRx register.

*Note:* The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

When a given channel is used as asymmetric PWM channel, its secondary channel can also be used. For instance, if an OC1REFC signal is generated on channel 1 (Asymmetric PWM mode 1), it is possible to output either the OC2REF signal on channel 2, or an OC2REFC signal resulting from asymmetric PWM mode 2.

Figure 316 shows an example of signals that can be generated using Asymmetric PWM mode (channels 1 to 4 are configured in Asymmetric PWM mode 1).

**Figure 316. Generation of 2 phase-shifted PWM signals with 50% duty cycle**

### 31.3.11 Combined PWM mode

Combined PWM mode allows two edge or center-aligned PWM signals to be generated with programmable delay and phase shift between respective pulses. While the frequency is determined by the value of the TIMx\_ARR register, the duty cycle and delay are determined by the two TIMx\_CCRx registers. The resulting signals, OCxREFC, are made of an OR or AND logical combination of two reference PWMs:

- OC1REFC (or OC2REFC) is controlled by TIMx\_CCR1 and TIMx\_CCR2
- OC3REFC (or OC4REFC) is controlled by TIMx\_CCR3 and TIMx\_CCR4

Combined PWM mode can be selected independently on two channels (one OCx output per pair of CCR registers) by writing '1100' (Combined PWM mode 1) or '1101' (Combined PWM mode 2) in the OCxM bits in the TIMx\_CCMRx register.

When a given channel is used as combined PWM channel, its secondary channel must be configured in the opposite PWM mode (for instance, one in Combined PWM mode 1 and the other in Combined PWM mode 2).

*Note: The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.*

*Figure 317* shows an example of signals that can be generated using Asymmetric PWM mode, obtained with the following configuration:

- Channel 1 is configured in Combined PWM mode 2,
- Channel 2 is configured in PWM mode 1,
- Channel 3 is configured in Combined PWM mode 2,
- Channel 4 is configured in PWM mode 1

Figure 317. Combined PWM mode on channels 1 and 3

### 31.3.12 Clearing the OCxREF signal on an external event

The OCxREF signal of a given channel can be cleared when a high level is applied on the ocref\_clr\_int input (OCxCE enable bit in the corresponding TIMx\_CCMRx register set to 1). OCxREF remains low until the next transition to the active state, on the following PWM cycle. This function can only be used in Output compare and PWM modes. It does not work in Forced mode.

OCREF\_CLR\_INPUT can be selected between the OCREF\_CLR input and ETRF (ETR after the filter) by configuring the OCCS bit in the TIMx\_SMCR register.

The OCxREF signal for a given channel can be reset by applying a high level on the ETRF input (OCxCE enable bit set to 1 in the corresponding TIMx\_CCMRx register). OCxREF remains low until the next transition to the active state, on the following PWM cycle.

This function can be used only in the output compare and PWM modes. It does not work in forced mode.

For example, the OCxREF signal can be connected to the output of a comparator to be used for current handling. In this case, ETR must be configured as follows:

1. The external trigger prescaler should be kept off: bits ETPS[1:0] in the TIMx\_SMCR register are cleared to 00.
2. The external clock mode 2 must be disabled: bit ECE in the TIM1\_SMCR register is cleared to 0.
3. The external trigger polarity (ETP) and the external trigger filter (ETF) can be configured according to the application's needs.

Figure 318 shows the behavior of the OCxREF signal when the ETRF input becomes high, for both values of the OCxCE enable bit. In this example, the timer TIMx is programmed in PWM mode.

**Figure 318. Clearing TIMx OCxREF**

**Note:**

*In case of a PWM with a 100% duty cycle (if  $CCR_x > ARR$ ), OCxREF is enabled again at the next counter overflow.*

### 31.3.13 One-pulse mode

One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. One-pulse mode is selected by setting the OPM bit in the TIMx\_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be:

- $CNT < CCRx \leq ARR$  (in particular,  $0 < CCRx$ ),

**Figure 319. Example of one-pulse mode.**

For example one may want to generate a positive pulse on OC1 with a length of  $t_{PULSE}$  and after a delay of  $t_{DELAY}$  as soon as a positive edge is detected on the TI2 input pin.

Let's use TI2FP2 as trigger 1:

1. Map TI2FP2 on TI2 by writing CC2S=01 in the TIMx\_CCMR1 register.
2. TI2FP2 must detect a rising edge, write CC2P=0 and CC2NP='0' in the TIMx\_CCER register.
3. Configure TI2FP2 as trigger for the slave mode controller (TRGI) by writing TS=110 in the TIMx\_SMCR register.
4. TI2FP2 is used to start the counter by writing SMS to '110 in the TIMx\_SMCR register (trigger mode).

The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler).

- The  $t_{\text{DELAY}}$  is defined by the value written in the TIMx\_CCR1 register.
- The  $t_{\text{PULSE}}$  is defined by the difference between the auto-reload value and the compare value (TIMx\_ARR - TIMx\_CCR1).
- Let's say one want to build a waveform with a transition from '0' to '1' when a compare match occurs and a transition from '1' to '0' when the counter reaches the auto-reload value. To do this PWM mode 2 must be enabled by writing OC1M=111 in the TIMx\_CCMR1 register. Optionally the preload registers can be enabled by writing OC1PE=1 in the TIMx\_CCMR1 register and ARPE in the TIMx\_CR1 register. In this case one has to write the compare value in the TIMx\_CCR1 register, the auto-reload value in the TIMx\_ARR register, generate an update by setting the UG bit and wait for external trigger event on TI2. CC1P is written to '0' in this example.

In our example, the DIR and CMS bits in the TIMx\_CR1 register should be low.

Since only 1 pulse (Single mode) is needed, a 1 must be written in the OPM bit in the TIMx\_CR1 register to stop the counter at the next update event (when the counter rolls over from the auto-reload value back to 0). When OPM bit in the TIMx\_CR1 register is set to '0', so the Repetitive Mode is selected.

#### Particular case: OCx fast enable:

In One-pulse mode, the edge detection on TIx input set the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations and it limits the minimum delay  $t_{\text{DELAY min}}$  we can get.

If one wants to output a waveform with the minimum delay, the OCxFE bit can be set in the TIMx\_CCMRx register. Then OCxRef (and OCx) is forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

### 31.3.14 Retriggerable one pulse mode

This mode allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length, but with the following differences with Non-retriggerable one pulse mode described in [Section 31.3.13](#):

- The pulse starts as soon as the trigger occurs (no programmable delay)
- The pulse is extended if a new trigger occurs before the previous one is completed

The timer must be in Slave mode, with the bits SMS[3:0] = '1000' (Combined Reset + trigger mode) in the TIMx\_SMCR register, and the OCxM[3:0] bits set to '1000' or '1001' for Retriggerable OPM mode 1 or 2.

If the timer is configured in Up-counting mode, the corresponding CCRx must be set to 0 (the ARR register sets the pulse length). If the timer is configured in Down-counting mode CCRx must be above or equal to ARR.

*Note:* In retriggerable one pulse mode, the CCxIF flag is not significant.

*The OCxM[3:0] and SMS[3:0] bit fields are split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.*

*This mode must not be used with center-aligned PWM modes. It is mandatory to have CMS[1:0] = 00 in TIMx\_CR1.*

Figure 320. Retriggerable one-pulse mode

### 31.3.15 Encoder interface mode

To select Encoder Interface mode write SMS='001 in the TIMx\_SMCR register if the counter is counting on TI2 edges only, SMS=010 if it is counting on TI1 edges only and SMS=011 if it is counting on both TI1 and TI2 edges.

Select the TI1 and TI2 polarity by programming the CC1P and CC2P bits in the TIMx\_CCER register. CC1NP and CC2NP must be kept cleared. When needed, the input filter can be programmed as well. CC1NP and CC2NP must be kept low.

The two inputs TI1 and TI2 are used to interface to an incremental encoder. Refer to [Table 202](#). The counter is clocked by each valid transition on TI1FP1 or TI2FP2 (TI1 and TI2 after input filter and polarity selection, TI1FP1=TI1 if not filtered and not inverted, TI2FP2=TI2 if not filtered and not inverted) assuming that it is enabled (CEN bit in TIMx\_CR1 register written to '1'). The sequence of transitions of the two inputs is evaluated and generates count pulses as well as the direction signal. Depending on the sequence the counter counts up or down, the DIR bit in the TIMx\_CR1 register is modified by hardware accordingly. The DIR bit is calculated at each transition on any input (TI1 or TI2), whatever the counter is counting on TI1 only, TI2 only or both TI1 and TI2.

Encoder interface mode acts simply as an external clock with direction selection. This means that the counter just counts continuously between 0 and the auto-reload value in the TIMx\_ARR register (0 to ARR or ARR down to 0 depending on the direction). So the TIMx\_ARR must be configured before starting. In the same way, the capture, compare, prescaler, trigger output features continue to work as normal.

In this mode, the counter is modified automatically following the speed and the direction of the-quadrature encoder and its content, therefore, always represents the encoder's position. The count direction correspond to the rotation direction of the connected sensor. The table summarizes the possible combinations, assuming TI1 and TI2 do not switch at the same time.

**Table 202. Counting direction versus encoder signals**

| Active edge             | Level on opposite signal (TI1FP1 for TI2, TI2FP2 for TI1) | TI1FP1 signal |          | TI2FP2 signal |          |
|-------------------------|-----------------------------------------------------------|---------------|----------|---------------|----------|
|                         |                                                           | Rising        | Falling  | Rising        | Falling  |
| Counting on TI1 only    | High                                                      | Down          | Up       | No Count      | No Count |
|                         | Low                                                       | Up            | Down     | No Count      | No Count |
| Counting on TI2 only    | High                                                      | No Count      | No Count | Up            | Down     |
|                         | Low                                                       | No Count      | No Count | Down          | Up       |
| Counting on TI1 and TI2 | High                                                      | Down          | Up       | Up            | Down     |
|                         | Low                                                       | Up            | Down     | Down          | Up       |

An external incremental encoder can be connected directly to the MCU without external interface logic. However, comparators are normally be used to convert the encoder's differential outputs to digital signals. This greatly increases noise immunity. The third encoder output which indicate the mechanical zero position, may be connected to an external interrupt input and trigger a counter reset.

*Figure 321* gives an example of counter operation, showing count signal generation and direction control. It also shows how input jitter is compensated where both edges are selected. This might occur if the sensor is positioned near to one of the switching points. For this example we assume that the configuration is the following:

- CC1S= 01 (TIMx\_CCMR1 register, TI1FP1 mapped on TI1)
- CC2S= 01 (TIMx\_CCMR1 register, TI2FP2 mapped on TI2)
- CC1P and CC1NP = '0' (TIMx\_CCER register, TI1FP1 noninverted, TI1FP1=TI1)
- CC2P and CC2NP = '0' (TIMx\_CCER register, TI2FP2 noninverted, TI2FP2=TI2)
- SMS= 011 (TIMx\_SMCR register, both inputs are active on both rising and falling edges)
- CEN= 1 (TIMx\_CR1 register, Counter is enabled)

**Figure 321. Example of counter operation in encoder interface mode**

*Figure 322* gives an example of counter behavior when TI1FP1 polarity is inverted (same configuration as above except CC1P=1).

**Figure 322. Example of encoder interface mode with TI1FP1 polarity inverted**

The timer, when configured in Encoder Interface mode provides information on the sensor's current position. Dynamic information can be obtained (speed, acceleration, deceleration) by measuring the period between two encoder events using a second timer configured in capture mode. The output of the encoder which indicates the mechanical zero can be used for this purpose. Depending on the time between two events, the counter can also be read at regular times. This can be done by latching the counter value into a third input capture register if available (then the capture signal must be periodic and can be generated by another timer). when available, it is also possible to read its value through a DMA request generated by a Real-Time clock.

### 31.3.16 UIF bit remapping

The IUFREMAP bit in the TIMx\_CR1 register forces a continuous copy of the update interrupt flag (UIF) into bit 31 of the timer counter register's bit 31 (TIMxCNT[31]). This permits to atomically read both the counter value and a potential roll-over condition signaled by the UIFCPY flag. It eases the calculation of angular speed by avoiding race conditions caused, for instance, by a processing shared between a background task (counter reading) and an interrupt (update interrupt).

There is no latency between the UIF and UIFCPY flag assertions.

In 32-bit timer implementations, when the IUFREMAP bit is set, bit 31 of the counter is overwritten by the UIFCPY flag upon read access (the counter's most significant bit is only accessible in write mode).

### 31.3.17 Timer input XOR function

The TI1S bit in the TIM1xx\_CR2 register, allows the input filter of channel 1 to be connected to the output of a XOR gate, combining the three input pins TIMx\_CH1 to TIMx\_CH3.

The XOR output can be used with all the timer input functions such as trigger or input capture.

An example of this feature used to interface Hall sensors is given in [Section 30.3.25: Interfacing with Hall sensors on page 947](#).

### 31.3.18 Timers and external trigger synchronization

The TIMx Timers can be synchronized with an external trigger in several modes: Reset mode, Gated mode and Trigger mode.

#### Slave mode: Reset mode

The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIMx\_CR1 register is low, an update event UEV is generated. Then all the preloaded registers (TIMx\_ARR, TIMx\_CCRx) are updated.

In the following example, the upcounter is cleared in response to a rising edge on TI1 input:

1. Configure the channel 1 to detect rising edges on TI1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S = 01 in the TIMx\_CCMR1 register. Write CC1P=0 and CC1NP=0 in TIMx\_CCER register to validate the polarity (and detect rising edges only).
2. Configure the timer in reset mode by writing SMS=100 in TIMx\_SMCR register. Select TI1 as the input source by writing TS=101 in TIMx\_SMCR register.
3. Start the counter by writing CEN=1 in the TIMx\_CR1 register.

The counter starts counting on the internal clock, then behaves normally until TI1 rising edge. When TI1 rises, the counter is cleared and restarts from 0. In the meantime, the trigger flag is set (TIF bit in the TIMx\_SR register) and an interrupt request, or a DMA request can be sent if enabled (depending on the TIE and TDE bits in TIMx\_DIER register).

The following figure shows this behavior when the auto-reload register TIMx\_ARR=0x36. The delay between the rising edge on TI1 and the actual reset of the counter is due to the resynchronization circuit on TI1 input.

**Figure 323. Control circuit in reset mode**

#### Slave mode: Gated mode

The counter can be enabled depending on the level of a selected input.

In the following example, the upcounter counts only when TI1 input is low:

1. Configure the channel 1 to detect low levels on TI1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S=01 in TIMx\_CCMR1 register. Write CC1P=1 and CC1NP=0 in TIMx\_CCER register to validate the polarity (and detect low level only).
2. Configure the timer in gated mode by writing SMS=101 in TIMx\_SMCR register. Select TI1 as the input source by writing TS=101 in TIMx\_SMCR register.
3. Enable the counter by writing CEN=1 in the TIMx\_CR1 register (in gated mode, the counter doesn't start if CEN=0, whatever is the trigger input level).

The counter starts counting on the internal clock as long as TI1 is low and stops as soon as TI1 becomes high. The TIF flag in the TIMx\_SR register is set both when the counter starts or stops.

The delay between the rising edge on TI1 and the actual stop of the counter is due to the resynchronization circuit on TI1 input.

**Figure 324. Control circuit in gated mode**

1. The configuration "CCxP=CCxNP=1" (detection of both rising and falling edges) does not have any effect in gated mode because gated mode acts on a level and not on an edge.

**Note:** *The configuration "CCxP=CCxNP=1" (detection of both rising and falling edges) does not have any effect in gated mode because gated mode acts on a level and not on an edge.*

### Slave mode: Trigger mode

The counter can start in response to an event on a selected input.

In the following example, the upcounter starts in response to a rising edge on TI2 input:

1. Configure the channel 2 to detect rising edges on TI2. Configure the input filter duration (in this example, we do not need any filter, so we keep IC2F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. CC2S bits are selecting the input capture source only, CC2S=01 in TIMx\_CCMR1 register. Write

CC2P=1 and CC2NP=0 in TIMx\_CCER register to validate the polarity (and detect low level only).

2. Configure the timer in trigger mode by writing SMS=110 in TIMx\_SMCR register. Select TI2 as the input source by writing TS=110 in TIMx\_SMCR register.

When a rising edge occurs on TI2, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on TI2 and the actual start of the counter is due to the resynchronization circuit on TI2 input.

**Figure 325. Control circuit in trigger mode**

MS31403V1

### Slave mode: Combined reset + trigger mode

In this case, a rising edge of the selected trigger input (TRGI) reinitializes the counter, generates an update of the registers, and starts the counter.

This mode is used for one-pulse mode.

### Slave mode: External Clock mode 2 + trigger mode

The external clock mode 2 can be used in addition to another slave mode (except external clock mode 1 and encoder mode). In this case, the ETR signal is used as external clock input, and another input can be selected as trigger input when operating in reset mode, gated mode or trigger mode. It is recommended not to select ETR as TRGI through the TS bits of TIMx\_SMCR register.

In the following example, the upcounter is incremented at each rising edge of the ETR signal as soon as a rising edge of TI1 occurs:

1. Configure the external trigger input circuit by programming the TIMx\_SMCR register as follows:
  - ETF = 0000: no filter
  - ETPS=00: prescaler disabled
  - ETP=0: detection of rising edges on ETR and ECE=1 to enable the external clock mode 2.
2. Configure the channel 1 as follows, to detect rising edges on TI:
  - IC1F=0000: no filter.
  - The capture prescaler is not used for triggering and does not need to be configured.
  - CC1S=01 in TIMx\_CCMR1 register to select only the input capture source
  - CC1P=0 and CC1NP=0 in TIMx\_CCER register to validate the polarity (and detect rising edge only).
3. Configure the timer in trigger mode by writing SMS=110 in TIMx\_SMCR register. Select TI1 as the input source by writing TS=101 in TIMx\_SMCR register.

A rising edge on TI1 enables the counter and sets the TIF flag. The counter then counts on ETR rising edges.

The delay between the rising edge of the ETR signal and the actual reset of the counter is due to the resynchronization circuit on ETRP input.

**Figure 326. Control circuit in external clock mode 2 + trigger mode**

### 31.3.19 Timer synchronization

The TIMx timers are linked together internally for timer synchronization or chaining. When one Timer is configured in Master Mode, it can reset, start, stop or clock the counter of another Timer configured in Slave Mode.

*Figure 327: Master/Slave timer example* and *Figure 328: Master/slave connection example with 1 channel only timers* present an overview of the trigger selection and the master mode selection blocks.

Figure 327. Master/Slave timer example

Figure 328. Master/slave connection example with 1 channel only timers

Note:

The timers with one channel only (see [Figure 328](#)) do not feature a master mode. However, the OC1 output signal can be used to trigger some other timers (including timers described in other sections of this document). Check the “TIMx internal trigger connection” table of any TIMx\_SMCR register on the device to identify which timers can be targeted as slave. The OC1 signal pulse width must be programmed to be at least 2 clock cycles of the destination timer, to make sure the slave timer detects the trigger. For instance, if the destination's timer CK\_INT clock is 4 times slower than the source timer, the OC1 pulse width must be 8 clock cycles.

### Using one timer as prescaler for another timer

For example, TIM3 can be configured to act as a prescaler for TIM2. Refer to [Figure 327](#). To do this:

1. Configure TIM3 in master mode so that it outputs a periodic trigger signal on each update event UEV. If MMS=010 is written in the TIM3\_CR2 register, a rising edge is output on TRGO each time an update event is generated.
2. To connect the TRGO output of TIM3 to TIM2, TIM2 must be configured in slave mode using ITR2 as internal trigger. This is selected through the TS bits in the TIM2\_SMCR register (writing TS=010).
3. Then the slave mode controller must be put in external clock mode 1 (write SMS=111 in the TIM2\_SMCR register). This causes TIM2 to be clocked by the rising edge of the periodic TIM3 trigger signal (which correspond to the TIM3 counter overflow).
4. Finally both timers must be enabled by setting their respective CEN bits (TIMx\_CR1 register).

**Note:** If OCx is selected on TIM3 as the trigger output (MMS=1xx), its rising edge is used to clock the counter of TIM2.

### Using one timer to enable another timer

In this example, we control the enable of TIM2 with the output compare 1 of Timer 3. Refer to [Figure 327](#) for connections. TIM2 counts on the divided internal clock only when OC1REF of TIM3 is high. Both counter clock frequencies are divided by 3 by the prescaler compared to CK\_INT ( $f_{CK\_CNT} = f_{CK\_INT}/3$ ).

1. Configure TIM3 master mode to send its Output Compare 1 Reference (OC1REF) signal as trigger output (MMS=100 in the TIM3\_CR2 register).
2. Configure the TIM3 OC1REF waveform (TIM3\_CCMR1 register).
3. Configure TIM2 to get the input trigger from TIM3 (TS=010 in the TIM2\_SMCR register).
4. Configure TIM2 in gated mode (SMS=101 in TIM2\_SMCR register).
5. Enable TIM2 by writing '1' in the CEN bit (TIM2\_CR1 register).
6. Start TIM3 by writing '1' in the CEN bit (TIM3\_CR1 register).

**Note:** The counter 2 clock is not synchronized with counter 1, this mode only affects the TIM2 counter enable signal.

**Figure 329. Gating TIM2 with OC1REF of TIM3**

In the example in [Figure 329](#), the TIM2 counter and prescaler are not initialized before being started. So they start counting from their current value. It is possible to start from a given value by resetting both timers before starting TIM3. Then any value can be written in the timer counters. The timers can easily be reset by software using the UG bit in the TIMx\_EGR registers.

In the next example (refer to [Figure 330](#)), we synchronize TIM3 and TIM2. TIM3 is the master and starts from 0. TIM2 is the slave and starts from 0xE7. The prescaler ratio is the same for both timers. TIM2 stops when TIM3 is disabled by writing '0' to the CEN bit in the TIM3\_CR1 register:

1. Configure TIM3 master mode to send its Output Compare 1 Reference (OC1REF) signal as trigger output (MMS=100 in the TIM3\_CR2 register).
2. Configure the TIM3 OC1REF waveform (TIM3\_CCMR1 register).
3. Configure TIM2 to get the input trigger from TIM3 (TS=010 in the TIM2\_SMCR register).
4. Configure TIM2 in gated mode (SMS=101 in TIM2\_SMCR register).
5. Reset TIM3 by writing '1' in UG bit (TIM3\_EGR register).
6. Reset TIM2 by writing '1' in UG bit (TIM2\_EGR register).
7. Initialize TIM2 to 0xE7 by writing '0xE7' in the TIM2 counter (TIM2\_CNT).
8. Enable TIM2 by writing '1' in the CEN bit (TIM2\_CR1 register).
9. Start TIM3 by writing '1' in the CEN bit (TIM3\_CR1 register).
10. Stop TIM3 by writing '0' in the CEN bit (TIM3\_CR1 register).

**Figure 330. Gating TIM2 with Enable of TIM3**

MS33120V1

### Using one timer to start another timer

In this example, we set the enable of Timer 2 with the update event of Timer 3. Refer to [Figure 327](#) for connections. Timer 2 starts counting from its current value (which can be non-zero) on the divided internal clock as soon as the update event is generated by Timer 1. When Timer 2 receives the trigger signal its CEN bit is automatically set and the counter counts until we write '0' to the CEN bit in the TIM2\_CR1 register. Both counter clock frequencies are divided by 3 by the prescaler compared to CK\_INT ( $f_{CK\_CNT} = f_{CK\_INT}/3$ ).

1. Configure TIM3 master mode to send its Update Event (UEV) as trigger output (MMS=010 in the TIM3\_CR2 register).
2. Configure the TIM3 period (TIM3\_ARR registers).
3. Configure TIM2 to get the input trigger from TIM3 (TS=010 in the TIM2\_SMCR register).
4. Configure TIM2 in trigger mode (SMS=110 in TIM2\_SMCR register).
5. Start TIM3 by writing '1 in the CEN bit (TIM3\_CR1 register).

**Figure 331. Triggering TIM2 with update of TIM3**

As in the previous example, both counters can be initialized before starting counting. [Figure 332](#) shows the behavior with the same configuration as in [Figure 331](#) but in trigger mode instead of gated mode (SMS=110 in the TIM2\_SMCR register).

**Figure 332. Triggering TIM2 with Enable of TIM3**

### Starting 2 timers synchronously in response to an external trigger

In this example, we set the enable of TIM3 when its TI1 input rises, and the enable of TIM2 with the enable of TIM3. Refer to [Figure 327](#) for connections. To ensure the counters are

aligned, TIM3 must be configured in Master/Slave mode (slave with respect to TI1, master with respect to TIM2):

1. Configure TIM3 master mode to send its Enable as trigger output (MMS=001 in the TIM3\_CR2 register).
2. Configure TIM3 slave mode to get the input trigger from TI1 (TS=100 in the TIM3\_SMCR register).
3. Configure TIM3 in trigger mode (SMS=110 in the TIM3\_SMCR register).
4. Configure the TIM3 in Master/Slave mode by writing MSM=1 (TIM3\_SMCR register).
5. Configure TIM2 to get the input trigger from TIM3 (TS=000 in the TIM2\_SMCR register).
6. Configure TIM2 in trigger mode (SMS=110 in the TIM2\_SMCR register).

When a rising edge occurs on TI1 (TIM3), both counters starts counting synchronously on the internal clock and both TIF flags are set.

**Note:** *In this example both timers are initialized before starting (by setting their respective UG bits). Both counters starts from 0, but an offset can easily be inserted between them by writing any of the counter registers (TIMx\_CNT). One can see that the master/slave mode insert a delay between CNT\_EN and CK\_PSC on TIM3.*

**Figure 333. Triggering TIM3 and TIM2 with TIM3 TI1 input**

**Note:** *The clock of the slave peripherals (timer, ADC, ...) receiving the TRGO or the TRGO2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.*

### 31.3.20 DMA burst mode

The TIMx timers have the capability to generate multiple DMA requests upon a single event. The main purpose is to be able to re-program part of the timer multiple times without software overhead, but it can also be used to read several registers in a row, at regular intervals.

The DMA controller destination is unique and must point to the virtual register TIMx\_DMAR. On a given timer event, the timer launches a sequence of DMA requests (burst). Each write into the TIMx\_DMAR register is actually redirected to one of the timer registers.

The DBL[4:0] bits in the TIMx\_DCR register set the DMA burst length. The timer recognizes a burst transfer when a read or a write access is done to the TIMx\_DMAR address, i.e. the number of transfers (either in half-words or in bytes).

The DBA[4:0] bits in the TIMx\_DCR registers define the DMA base address for DMA transfers (when read/write access are done through the TIMx\_DMAR address). DBA is defined as an offset starting from the address of the TIMx\_CR1 register:

Example:

00000: TIMx\_CR1

00001: TIMx\_CR2

00010: TIMx\_SMCR

As an example, the timer DMA burst feature is used to update the contents of the CCRx registers (x = 2, 3, 4) upon an update event, with the DMA transferring half words into the CCRx registers.

This is done in the following steps:

1. Configure the corresponding DMA channel as follows:
  - DMA channel peripheral address is the DMAR register address
  - DMA channel memory address is the address of the buffer in the RAM containing the data to be transferred by DMA into CCRx registers.
  - Number of data to transfer = 3 (See note below).
  - Circular mode disabled.
2. Configure the DCR register by configuring the DBA and DBL bit fields as follows:  
DBL = 3 transfers, DBA = 0xE.
3. Enable the TIMx update DMA request (set the UDE bit in the DIER register).
4. Enable TIMx
5. Enable the DMA channel

This example is for the case where every CCRx register has to be updated once. If every CCRx register is to be updated twice for example, the number of data to transfer should be 6. Let's take the example of a buffer in the RAM containing data1, data2, data3, data4, data5 and data6. The data is transferred to the CCRx registers as follows: on the first update DMA request, data1 is transferred to CCR2, data2 is transferred to CCR3, data3 is transferred to CCR4 and on the second update DMA request, data4 is transferred to CCR2, data5 is transferred to CCR3 and data6 is transferred to CCR4.

*Note:* A null value can be written to the reserved registers.

### 31.3.21 Debug mode

When the microcontroller enters debug mode (Cortex<sup>®</sup>-M4 core - halted), the TIMx counter either continues to work normally or stops, depending on DBG\_TIMx\_STOP configuration bit in DBGMCU module. For more details, refer to [Section 48.16.2: Debug support for timers, RTC, watchdog, bxCAN and I<sup>2</sup>C](#).

## 31.4 TIM2/TIM3/TIM4/TIM5 registers

Refer to [Section 1.2](#) for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

### 31.4.1 TIMx control register 1 (TIMx\_CR1)(x = 2 to 5)

Address offset: 0x00

Reset value: 0x0000

| 15   | 14   | 13   | 12   | 11           | 10   | 9        | 8   | 7    | 6        | 5   | 4   | 3   | 2   | 1    | 0   |
|------|------|------|------|--------------|------|----------|-----|------|----------|-----|-----|-----|-----|------|-----|
| Res. | Res. | Res. | Res. | UIFRE<br>MAP | Res. | CKD[1:0] |     | ARPE | CMS[1:0] |     | DIR | OPM | URS | UDIS | CEN |
|      |      |      |      | r/w          |      | r/w      | r/w | r/w  | r/w      | r/w | r/w | r/w | r/w | r/w  | r/w |

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 **UIFREMAP**: UIF status bit remapping

0: No remapping. UIF status bit is not copied to TIMx\_CNT register bit 31.

1: Remapping enabled. UIF status bit is copied to TIMx\_CNT register bit 31.

Bit 10 Reserved, must be kept at reset value.

Bits 9:8 **CKD[1:0]**: Clock division

This bit-field indicates the division ratio between the timer clock (CK\_INT) frequency and sampling clock used by the digital filters (ETR, Tlx),

00:  $t_{DTS} = t_{CK\_INT}$

01:  $t_{DTS} = 2 \times t_{CK\_INT}$

10:  $t_{DTS} = 4 \times t_{CK\_INT}$

11: Reserved

Bit 7 **ARPE**: Auto-reload preload enable

0: TIMx\_ARR register is not buffered

1: TIMx\_ARR register is buffered

Bits 6:5 **CMS[1:0]**: Center-aligned mode selection

00: Edge-aligned mode. The counter counts up or down depending on the direction bit (DIR).

01: Center-aligned mode 1. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx\_CCMRx register) are set only when the counter is counting down.

10: Center-aligned mode 2. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx\_CCMRx register) are set only when the counter is counting up.

11: Center-aligned mode 3. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx\_CCMRx register) are set both when the counter is counting up or down.

*Note: It is not allowed to switch from edge-aligned mode to center-aligned mode as long as the counter is enabled (CEN=1)*

Bit 4 **DIR**: Direction

0: Counter used as upcounter

1: Counter used as downcounter

*Note: This bit is read only when the timer is configured in Center-aligned mode or Encoder mode.*

Bit 3 **OPM**: One-pulse mode

0: Counter is not stopped at update event

1: Counter stops counting at the next update event (clearing the bit CEN)

Bit 2 **URS**: Update request source

This bit is set and cleared by software to select the UEV event sources.

0: Any of the following events generate an update interrupt or DMA request if enabled.

These events can be:

- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller

1: Only counter overflow/underflow generates an update interrupt or DMA request if enabled.

Bit 1 **UDIS**: Update disable

This bit is set and cleared by software to enable/disable UEV event generation.

0: UEV enabled. The Update (UEV) event is generated by one of the following events:

- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller

Buffered registers are then loaded with their preload values.

1: UEV disabled. The Update event is not generated, shadow registers keep their value (ARR, PSC, CCRx). However the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.

Bit 0 **CEN**: Counter enable

0: Counter disabled

1: Counter enabled

*Note: External clock, gated mode and encoder mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.*

CEN is cleared automatically in one-pulse mode, when an update event occurs.

### 31.4.2 TIMx control register 2 (TIMx\_CR2)(x = 2 to 5)

Address offset: 0x04

Reset value: 0x0000

| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6        | 5  | 4  | 3    | 2    | 1    | 0    |
|------|------|------|------|------|------|------|------|------|----------|----|----|------|------|------|------|
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | TI1S | MMS[2:0] |    |    | CCDS | Res. | Res. | Res. |
|      |      |      |      |      |      |      |      | rw   | rw       | rw | rw | rw   |      |      |      |

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **TI1S**: TI1 selection

- 0: The TIMx\_CH1 pin is connected to TI1 input
  - 1: The TIMx\_CH1, CH2 and CH3 pins are connected to the TI1 input (XOR combination)
- See also [Section 30.3.25: Interfacing with Hall sensors on page 947](#)

Bits 6:4 **MMS[2:0]**: Master mode selection

These bits permit to select the information to be sent in master mode to slave timers for synchronization (TRGO). The combination is as follows:

000: **Reset** - the UG bit from the TIMx\_EGR register is used as trigger output (TRGO). If the reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on TRGO is delayed compared to the actual reset.

001: **Enable** - the Counter enable signal, CNT\_EN, is used as trigger output (TRGO). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic AND between CEN control bit and the trigger input when configured in gated mode.

When the Counter Enable signal is controlled by the trigger input, there is a delay on TRGO, except if the master/slave mode is selected (see the MSM bit description in TIMx\_SMCR register).

010: **Update** - The update event is selected as trigger output (TRGO). For instance a master timer can then be used as a prescaler for a slave timer.

011: **Compare Pulse** - The trigger output send a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or a compare match occurred. (TRGO)

100: **Compare** - OC1REFC signal is used as trigger output (TRGO)

101: **Compare** - OC2REFC signal is used as trigger output (TRGO)

110: **Compare** - OC3REFC signal is used as trigger output (TRGO)

111: **Compare** - OC4REFC signal is used as trigger output (TRGO)

*Note: The clock of the slave timer or ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.*

Bit 3 **CCDS**: Capture/compare DMA selection

- 0: CCx DMA request sent when CCx event occurs
- 1: CCx DMA requests sent when update event occurs

Bits 2:0 Reserved, must be kept at reset value.

### 31.4.3 TIMx slave mode control register (TIMx\_SMCR)(x = 2 to 5)

Address offset: 0x08

Reset value: 0x0000 0000

|      |      |           |      |          |      |      |      |      |         |      |      |      |          |      |        |

| 31   | 30   | 29        | 28   | 27       | 26   | 25   | 24   | 23   | 22      | 21   | 20   | 19   | 18       | 17   | 16     |
| Res. | Res. | Res.      | Res. | Res.     | Res. | Res. | Res. | Res. | Res.    | Res. | Res. | Res. | Res.     | Res. | SMS[3] |
|      |      |           |      |          |      |      |      |      |         |      |      |      |          |      | rw     |
| 15   | 14   | 13        | 12   | 11       | 10   | 9    | 8    | 7    | 6       | 5    | 4    | 3    | 2        | 1    | 0      |
| ETP  | ECE  | ETPS[1:0] |      | ETF[3:0] |      |      |      | MSM  | TS[2:0] |      |      | OCCS | SMS[2:0] |      |        |
| rw   | rw   | rw        | rw   | rw       | rw   | rw   | rw   | rw   | rw      | rw   | rw   | rw   | rw       | rw   | rw     |

Bits 31:17 Reserved, must be kept at reset value.

Bit 15 **ETP**: External trigger polarity

This bit selects whether ETR or  $\overline{\text{ETR}}$  is used for trigger operations

0: ETR is non-inverted, active at high level or rising edge

1: ETR is inverted, active at low level or falling edge

Bit 14 **ECE**: External clock enable

This bit enables External clock mode 2.

0: External clock mode 2 disabled

1: External clock mode 2 enabled. The counter is clocked by any active edge on the ETRF signal.

*Note: Setting the ECE bit has the same effect as selecting external clock mode 1 with TRGI connected to ETRF (SMS=111 and TS=111).*

*It is possible to simultaneously use external clock mode 2 with the following slave modes: reset mode, gated mode and trigger mode. Nevertheless, TRGI must not be connected to ETRF in this case (TS bits must not be 111).*

*If external clock mode 1 and external clock mode 2 are enabled at the same time, the external clock input is ETRF.*

Bits 13:12 **ETPS[1:0]**: External trigger prescaler

External trigger signal ETRP frequency must be at most 1/4 of CK\_INT frequency. A prescaler can be enabled to reduce ETRP frequency. It is useful when inputting fast external clocks.

00: Prescaler OFF

01: ETRP frequency divided by 2

10: ETRP frequency divided by 4

11: ETRP frequency divided by 8

Bits 11:8 **ETF[3:0]**: External trigger filter

This bit-field then defines the frequency used to sample ETRP signal and the length of the digital filter applied to ETRP. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000: No filter, sampling is done at  $f_{DTS}$

0001:  $f_{SAMPLING}=f_{CK\_INT}$ , N=2

0010:  $f_{SAMPLING}=f_{CK\_INT}$ , N=4

0011:  $f_{SAMPLING}=f_{CK\_INT}$ , N=8

0100:  $f_{SAMPLING}=f_{DTS}/2$ , N=6

0101:  $f_{SAMPLING}=f_{DTS}/2$ , N=8

0110:  $f_{SAMPLING}=f_{DTS}/4$ , N=6

0111:  $f_{SAMPLING}=f_{DTS}/4$ , N=8

1000:  $f_{SAMPLING}=f_{DTS}/8$ , N=6

1001:  $f_{SAMPLING}=f_{DTS}/8$ , N=8

1010:  $f_{SAMPLING}=f_{DTS}/16$ , N=5

1011:  $f_{SAMPLING}=f_{DTS}/16$ , N=6

1100:  $f_{SAMPLING}=f_{DTS}/16$ , N=8

1101:  $f_{SAMPLING}=f_{DTS}/32$ , N=5

1110:  $f_{SAMPLING}=f_{DTS}/32$ , N=6

1111:  $f_{SAMPLING}=f_{DTS}/32$ , N=8

Bit 7 **MSM**: Master/Slave mode

0: No action

1: The effect of an event on the trigger input (TRGI) is delayed to allow a perfect synchronization between the current timer and its slaves (through TRGO). It is useful if we want to synchronize several timers on a single external event.

Bits 6:4 **TS**: Trigger selection

This bit-field selects the trigger input to be used to synchronize the counter.

000: Internal Trigger 0 (ITR0).

001: Internal Trigger 1 (ITR1).

010: Internal Trigger 2 (ITR2).

011: Internal Trigger 3 (ITR3).

100: TI1 Edge Detector (TI1F\_ED)

101: Filtered Timer Input 1 (TI1FP1)

110: Filtered Timer Input 2 (TI2FP2)

111: External Trigger input (ETRF)

See [Table 203: TIMx internal trigger connection on page 1053](#) for more details on ITRx meaning for each Timer.

*Note: These bits must be changed only when they are not used (e.g. when SMS=000) to avoid wrong edge detections at the transition.*

Bit 3 **OCCS**: OCREF clear selection

This bit is used to select the OCREF clear source

0: OCREF\_CLR\_INT is connected to the OCREF\_CLR input

1: OCREF\_CLR\_INT is connected to ETRF

Bits 16, 2, 1, 0 **SMS[3:0]**: Slave mode selection

When external signals are selected the active edge of the trigger signal (TRGI) is linked to the polarity selected on the external input (see Input Control register and Control Register description).

0000: Slave mode disabled - if CEN = '1 then the prescaler is clocked directly by the internal clock.

0001: Encoder mode 1 - Counter counts up/down on TI1FP1 edge depending on TI2FP2 level.

0010: Encoder mode 2 - Counter counts up/down on TI2FP2 edge depending on TI1FP1 level.

0011: Encoder mode 3 - Counter counts up/down on both TI1FP1 and TI2FP2 edges depending on the level of the other input.

0100: Reset Mode - Rising edge of the selected trigger input (TRGI) reinitializes the counter and generates an update of the registers.

0101: Gated Mode - The counter clock is enabled when the trigger input (TRGI) is high. The counter stops (but is not reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

0110: Trigger Mode - The counter starts at a rising edge of the trigger TRGI (but it is not reset). Only the start of the counter is controlled.

0111: External Clock Mode 1 - Rising edges of the selected trigger (TRGI) clock the counter.

1000: Combined reset + trigger mode - Rising edge of the selected trigger input (TRGI) reinitializes the counter, generates an update of the registers and starts the counter.

*Note: The gated mode must not be used if TI1F\_ED is selected as the trigger input (TS=100). Indeed, TI1F\_ED outputs 1 pulse for each transition on TI1F, whereas the gated mode checks the level of the trigger signal.*

*Note: The clock of the slave peripherals (timer, ADC, ...) receiving the TRGO or the TRGO2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.*

Table 203. TIMx internal trigger connection

| Slave TIM | ITR0 (TS = 000) | ITR1 (TS = 001)                | ITR2 (TS = 010) | ITR3 (TS = 011) |
|-----------|-----------------|--------------------------------|-----------------|-----------------|
| TIM2      | TIM1            | TIM8/OTG_FS_SOF <sup>(1)</sup> | TIM3            | TIM4            |
| TIM3      | TIM1            | TIM2                           | TIM15           | TIM4            |
| TIM4      | TIM1            | TIM2                           | TIM3            | TIM8            |
| TIM5      | TIM2            | TIM3                           | TIM4            | TIM8            |

1. Depends on the bit ITR1\_RMP in TIM2\_OR1 register.

### 31.4.4 TIMx DMA/Interrupt enable register (TIMx\_DIER)(x = 2 to 5)

Address offset: 0x0C

Reset value: 0x0000

| 15   | 14  | 13   | 12    | 11    | 10    | 9     | 8   | 7    | 6   | 5    | 4     | 3     | 2     | 1     | 0   |

Bit 10 **CC2DE**: Capture/Compare 2 DMA request enable  
 0: CC2 DMA request disabled.  
 1: CC2 DMA request enabled.

Bit 9 **CC1DE**: Capture/Compare 1 DMA request enable  
 0: CC1 DMA request disabled.  
 1: CC1 DMA request enabled.

Bit 8 **UDE**: Update DMA request enable  
 0: Update DMA request disabled.  
 1: Update DMA request enabled.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **TIE**: Trigger interrupt enable  
 0: Trigger interrupt disabled.  
 1: Trigger interrupt enabled.

Bit 5 Reserved, must be kept at reset value.

Bit 4 **CC4IE**: Capture/Compare 4 interrupt enable  
 0: CC4 interrupt disabled.  
 1: CC4 interrupt enabled.

Bit 3 **CC3IE**: Capture/Compare 3 interrupt enable  
 0: CC3 interrupt disabled.  
 1: CC3 interrupt enabled.

Bit 2 **CC2IE**: Capture/Compare 2 interrupt enable  
 0: CC2 interrupt disabled.  
 1: CC2 interrupt enabled.

Bit 1 **CC1IE**: Capture/Compare 1 interrupt enable  
 0: CC1 interrupt disabled.  
 1: CC1 interrupt enabled.

Bit 0 **UIE**: Update interrupt enable  
 0: Update interrupt disabled.  
 1: Update interrupt enabled.

### 31.4.5 TIMx status register (TIMx\_SR)(x = 2 to 5)

Address offset: 0x10

Reset value: 0x0000

| 15   | 14   | 13   | 12    | 11    | 10    | 9     | 8    | 7    | 6     | 5    | 4     | 3     | 2     | 1     | 0     |
|------|------|------|-------|-------|-------|-------|------|------|-------|------|-------|-------|-------|-------|-------|
| Res. | Res. | Res. | CC4OF | CC3OF | CC2OF | CC1OF | Res. | Res. | TIF   | Res. | CC4IF | CC3IF | CC2IF | CC1IF | UIF   |
|      |      |      | rc_w0 | rc_w0 | rc_w0 | rc_w0 |      |      | rc_w0 |      | rc_w0 | rc_w0 | rc_w0 | rc_w0 | rc_w0 |

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **CC4OF**: Capture/Compare 4 overcapture flag  
 refer to CC1OF description

Bit 11 **CC3OF**: Capture/Compare 3 overcapture flag  
 refer to CC1OF description

Bit 10 **CC2OF**: Capture/compare 2 overcapture flag  
 refer to CC1OF description

Bit 9 **CC1OF**: Capture/Compare 1 overcapture flag  
 This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to '0'.  
 0: No overcapture has been detected.  
 1: The counter value has been captured in TIMx\_CCR1 register while CC1IF flag was already set

Bits 8:7 Reserved, must be kept at reset value.

Bit 6 **TIF**: Trigger interrupt flag  
 This flag is set by hardware on the TRG trigger event (active edge detected on TRGI input when the slave mode controller is enabled in all modes but gated mode. It is set when the counter starts or stops when gated mode is selected. It is cleared by software.  
 0: No trigger event occurred.  
 1: Trigger interrupt pending.

Bit 5 Reserved, must be kept at reset value.

- Bit 4 **CC4IF**: Capture/Compare 4 interrupt flag  
Refer to CC1IF description
- Bit 3 **CC3IF**: Capture/Compare 3 interrupt flag  
Refer to CC1IF description
- Bit 2 **CC2IF**: Capture/Compare 2 interrupt flag  
Refer to CC1IF description
- Bit 1 **CC1IF**: Capture/compare 1 interrupt flag  
This flag is set by hardware. It is cleared by software (input capture or output compare mode) or by reading the TIMx\_CCR1 register (input capture mode only).  
0: No compare match / No input capture occurred  
1: A compare match or an input capture occurred  
**If channel CC1 is configured as output**: this flag is set when the content of the counter TIMx\_CNT matches the content of the TIMx\_CCR1 register. When the content of TIMx\_CCR1 is greater than the content of TIMx\_ARR, the CC1IF bit goes high on the counter overflow (in up-counting and up/down-counting modes) or underflow (in down-counting mode). There are 3 possible options for flag setting in center-aligned mode, refer to the CMS bits in the TIMx\_CR1 register for the full description.  
**If channel CC1 is configured as input**: this bit is set when counter value has been captured in TIMx\_CCR1 register (an edge has been detected on IC1, as per the edge sensitivity defined with the CC1P and CC1NP bits setting, in TIMx\_CCER).
- Bit 0 **UIF**: Update interrupt flag  
This bit is set by hardware on an update event. It is cleared by software.  
0: No update occurred  
1: Update interrupt pending. This bit is set by hardware when the registers are updated: At overflow or underflow (for TIM2 to TIM4) and if UDIS=0 in the TIMx\_CR1 register. When CNT is reinitialized by software using the UG bit in TIMx\_EGR register, if URS=0 and UDIS=0 in the TIMx\_CR1 register. When CNT is reinitialized by a trigger event (refer to the synchro control register description), if URS=0 and UDIS=0 in the TIMx\_CR1 register.

### 31.4.6 TIMx event generation register (TIMx\_EGR)(x = 2 to 5)

Address offset: 0x14

Reset value: 0x0000

| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6  | 5    | 4    | 3    | 2    | 1    | 0  |
|------|------|------|------|------|------|------|------|------|----|------|------|------|------|------|----|
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | TG | Res. | CC4G | CC3G | CC2G | CC1G | UG |
|      |      |      |      |      |      |      |      |      | w  |      | w    | w    | w    | w    | w  |

Bits 15:7 Reserved, must be kept at reset value.

Bit 6 **TG**: Trigger generation

This bit is set by software in order to generate an event, it is automatically cleared by hardware.

0: No action

1: The TIF flag is set in TIMx\_SR register. Related interrupt or DMA transfer can occur if enabled.

Bit 5 Reserved, must be kept at reset value.

Bit 4 **CC4G**: Capture/compare 4 generation

Refer to CC1G description

Bit 3 **CC3G**: Capture/compare 3 generation

Refer to CC1G description

Bit 2 **CC2G**: Capture/compare 2 generation

Refer to CC1G description

Bit 1 **CC1G**: Capture/compare 1 generation

This bit is set by software in order to generate an event, it is automatically cleared by hardware.

0: No action

1: A capture/compare event is generated on channel 1:

**If channel CC1 is configured as output:**

CC1IF flag is set, Corresponding interrupt or DMA request is sent if enabled.

**If channel CC1 is configured as input:**

The current value of the counter is captured in TIMx\_CCR1 register. The CC1IF flag is set, the corresponding interrupt or DMA request is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.

Bit 0 **UG**: Update generation

This bit can be set by software, it is automatically cleared by hardware.

0: No action

1: Re-initialize the counter and generates an update of the registers. Note that the prescaler counter is cleared too (anyway the prescaler ratio is not affected). The counter is cleared if the center-aligned mode is selected or if DIR=0 (upcounting), else it takes the auto-reload value (TIMx\_ARR) if DIR=1 (downcounting).

### 31.4.7 TIMx capture/compare mode register 1 (TIMx\_CCMR1)(x = 2 to 5)

Address offset: 0x18

Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode.

**Input capture mode:**

|           |      |      |      |             |      |           |      |           |      |      |      |             |      |           |      |
|-----------|------|------|------|-------------|------|-----------|------|-----------|------|------|------|-------------|------|-----------|------|
| 31        | 30   | 29   | 28   | 27          | 26   | 25        | 24   | 23        | 22   | 21   | 20   | 19          | 18   | 17        | 16   |
| Res.      | Res. | Res. | Res. | Res.        | Res. | Res.      | Res. | Res.      | Res. | Res. | Res. | Res.        | Res. | Res.      | Res. |
|           |      |      |      |             |      |           |      |           |      |      |      |             |      |           |      |
| 15        | 14   | 13   | 12   | 11          | 10   | 9         | 8    | 7         | 6    | 5    | 4    | 3           | 2    | 1         | 0    |
| IC2F[3:0] |      |      |      | IC2PSC[1:0] |      | CC2S[1:0] |      | IC1F[3:0] |      |      |      | IC1PSC[1:0] |      | CC1S[1:0] |      |
| rw        | rw   | rw   | rw   | rw          | rw   | rw        | rw   | rw        | rw   | rw   | rw   | rw          | rw   | rw        | rw   |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:12 **IC2F[3:0]**: Input capture 2 filter

Bits 11:10 **IC2PSC[1:0]**: Input capture 2 prescaler

Bits 9:8 **CC2S[1:0]**: Capture/compare 2 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC2 channel is configured as output.

01: CC2 channel is configured as input, IC2 is mapped on TI2.

10: CC2 channel is configured as input, IC2 is mapped on TI1.

11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note: CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIMx\_CCER).*

Bits 7:4 **IC1F[3:0]**: Input capture 1 filter

This bit-field defines the frequency used to sample TI1 input and the length of the digital filter applied to TI1. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000: No filter, sampling is done at  $f_{DTS}$

0001:  $f_{SAMPLING} = f_{CK\_INT}$ , N=2

0010:  $f_{SAMPLING} = f_{CK\_INT}$ , N=4

0011:  $f_{SAMPLING} = f_{CK\_INT}$ , N=8

0100:  $f_{SAMPLING} = f_{DTS}/2$ , N=6

0101:  $f_{SAMPLING} = f_{DTS}/2$ , N=8

0110:  $f_{SAMPLING} = f_{DTS}/4$ , N=6

0111:  $f_{SAMPLING} = f_{DTS}/4$ , N=8

1000:  $f_{SAMPLING} = f_{DTS}/8$ , N=6

1001:  $f_{SAMPLING} = f_{DTS}/8$ , N=8

1010:  $f_{SAMPLING} = f_{DTS}/16$ , N=5

1011:  $f_{SAMPLING} = f_{DTS}/16$ , N=6

1100:  $f_{SAMPLING} = f_{DTS}/16$ , N=8

1101:  $f_{SAMPLING} = f_{DTS}/32$ , N=5

1110:  $f_{SAMPLING} = f_{DTS}/32$ , N=6

1111:  $f_{SAMPLING} = f_{DTS}/32$ , N=8

Bits 3:2 **IC1PSC[1:0]**: Input capture 1 prescaler

This bit-field defines the ratio of the prescaler acting on CC1 input (IC1). The prescaler is reset as soon as CC1E=0 (TIMx\_CCER register).

00: no prescaler, capture is done each time an edge is detected on the capture input

01: capture is done once every 2 events

10: capture is done once every 4 events

11: capture is done once every 8 events

Bits 1:0 **CC1S[1:0]**: Capture/Compare 1 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC1 channel is configured as output

01: CC1 channel is configured as input, IC1 is mapped on TI1

10: CC1 channel is configured as input, IC1 is mapped on TI2

11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note: CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx\_CCER).*

### 31.4.8 TIMx capture/compare mode register 1 [alternate] (TIMx\_CCMR1) (x = 2 to 5)

Address offset: 0x18

Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode.

#### Output compare mode:

|       |           |      |      |       |       |           |         |       |           |      |      |       |       |           |         |
|-------|-----------|------|------|-------|-------|-----------|---------|-------|-----------|------|------|-------|-------|-----------|---------|
| 31    | 30        | 29   | 28   | 27    | 26    | 25        | 24      | 23    | 22        | 21   | 20   | 19    | 18    | 17        | 16      |
| Res.  | Res.      | Res. | Res. | Res.  | Res.  | Res.      | OC2M[3] | Res.  | Res.      | Res. | Res. | Res.  | Res.  | Res.      | OC1M[3] |
|       |           |      |      |       |       |           | rw      |       |           |      |      |       |       |           | rw      |
| 15    | 14        | 13   | 12   | 11    | 10    | 9         | 8       | 7     | 6         | 5    | 4    | 3     | 2     | 1         | 0       |
| OC2CE | OC2M[2:0] |      |      | OC2PE | OC2FE | CC2S[1:0] |         | OC1CE | OC1M[2:0] |      |      | OC1PE | OC1FE | CC1S[1:0] |         |
| rw    | rw        | rw   | rw   | rw    | rw    | rw        | rw      | rw    | rw        | rw   | rw   | rw    | rw    | rw        | rw      |

Bits 31:25 Reserved, must be kept at reset value.

Bits 23:17 Reserved, must be kept at reset value.

Bit 15 **OC2CE**: Output compare 2 clear enable

Bits 24, 14:12 **OC2M[3:0]**: Output compare 2 mode  
refer to OC1M description on bits 6:4

Bit 11 **OC2PE**: Output compare 2 preload enable

Bit 10 **OC2FE**: Output compare 2 fast enable

Bits 9:8 **CC2S[1:0]**: Capture/Compare 2 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC2 channel is configured as output

01: CC2 channel is configured as input, IC2 is mapped on TI2

10: CC2 channel is configured as input, IC2 is mapped on TI1

11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode is working only if an internal trigger input is selected through the TS bit (TIMx\_SMCR register)

*Note:* CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIMx\_CCER).

Bit 7 **OC1CE**: Output compare 1 clear enable

0: OC1Ref is not affected by the ETRF input

1: OC1Ref is cleared as soon as a High level is detected on ETRF input

Bits 16, 6:4 **OC1M[3:0]**: Output compare 1 mode

These bits define the behavior of the output reference signal OC1REF from which OC1 and OC1N are derived. OC1REF is active high whereas OC1 and OC1N active level depends on CC1P and CC1NP bits.

0000: Frozen - The comparison between the output compare register TIMx\_CCR1 and the counter TIMx\_CNT has no effect on the outputs. This mode can be used when the timer serves as a software timebase. When the frozen mode is enabled during timer operation, the output keeps the state (active or inactive) it had before entering the frozen state.

0001: Set channel 1 to active level on match. OC1REF signal is forced high when the counter TIMx\_CNT matches the capture/compare register 1 (TIMx\_CCR1).

0010: Set channel 1 to inactive level on match. OC1REF signal is forced low when the counter TIMx\_CNT matches the capture/compare register 1 (TIMx\_CCR1).

0011: Toggle - OC1REF toggles when TIMx\_CNT=TIMx\_CCR1.

0100: Force inactive level - OC1REF is forced low.

0101: Force active level - OC1REF is forced high.

0110: PWM mode 1 - In upcounting, channel 1 is active as long as TIMx\_CNT<TIMx\_CCR1 else inactive. In downcounting, channel 1 is inactive (OC1REF=0) as long as TIMx\_CNT>TIMx\_CCR1 else active (OC1REF=1).

0111: PWM mode 2 - In upcounting, channel 1 is inactive as long as TIMx\_CNT<TIMx\_CCR1 else active. In downcounting, channel 1 is active as long as TIMx\_CNT>TIMx\_CCR1 else inactive.

1000: Retriggerable OPM mode 1 - In up-counting mode, the channel is active until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update. In down-counting mode, the channel is inactive until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update.

1001: Retriggerable OPM mode 2 - In up-counting mode, the channel is inactive until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes inactive again at the next update. In down-counting mode, the channel is active until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update.

1010: Reserved,

1011: Reserved,

1100: Combined PWM mode 1 - OC1REF has the same behavior as in PWM mode 1. OC1REFC is the logical OR between OC1REF and OC2REF.

1101: Combined PWM mode 2 - OC1REF has the same behavior as in PWM mode 2. OC1REFC is the logical AND between OC1REF and OC2REF.

1110: Asymmetric PWM mode 1 - OC1REF has the same behavior as in PWM mode 1. OC1REFC outputs OC1REF when the counter is counting up, OC2REF when it is counting down.

1111: Asymmetric PWM mode 2 - OC1REF has the same behavior as in PWM mode 2. OC1REFC outputs OC1REF when the counter is counting up, OC2REF when it is counting down.

*Note: In PWM mode, the OCREF level changes only when the result of the comparison changes or when the output compare mode switches from "frozen" mode to "PWM" mode.*

*Note: The OC1M[3] bit is not contiguous, located in bit 16.*

Bit 3 **OC1PE**: Output compare 1 preload enable

0: Preload register on TIMx\_CCR1 disabled. TIMx\_CCR1 can be written at anytime, the new value is taken in account immediately.

1: Preload register on TIMx\_CCR1 enabled. Read/Write operations access the preload register. TIMx\_CCR1 preload value is loaded in the active register at each update event.

Bit 2 **OC1FE**: Output compare 1 fast enable

This bit decreases the latency between a trigger event and a transition on the timer output. It must be used in one-pulse mode (OPM bit set in TIMx\_CR1 register), to have the output pulse starting as soon as possible after the starting trigger.

0: CC1 behaves normally depending on counter and CCR1 values even when the trigger is ON. The minimum delay to activate CC1 output when an edge occurs on the trigger input is 5 clock cycles.

1: An active edge on the trigger input acts like a compare match on CC1 output. Then, OC is set to the compare level independently from the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OC1FE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 **CC1S[1:0]**: Capture/Compare 1 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC1 channel is configured as output.

01: CC1 channel is configured as input, IC1 is mapped on TI1.

10: CC1 channel is configured as input, IC1 is mapped on TI2.

11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note: CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx\_CCER).*

### 31.4.9 TIMx capture/compare mode register 2 (TIMx\_CCMR2)(x = 2 to 5)

Address offset: 0x1C

Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode.

**Input capture mode:**

|           |      |      |      |             |      |           |      |           |      |      |      |             |      |           |      |
|-----------|------|------|------|-------------|------|-----------|------|-----------|------|------|------|-------------|------|-----------|------|
| 31        | 30   | 29   | 28   | 27          | 26   | 25        | 24   | 23        | 22   | 21   | 20   | 19          | 18   | 17        | 16   |

| 15        | 14   | 13   | 12   | 11          | 10   | 9         | 8    | 7         | 6    | 5    | 4    | 3           | 2    | 1         | 0    |
| IC4F[3:0] |      |      |      | IC4PSC[1:0] |      | CC4S[1:0] |      | IC3F[3:0] |      |      |      | IC3PSC[1:0] |      | CC3S[1:0] |      |
| r/w       | r/w  | r/w  | r/w  | r/w         | r/w  | r/w       | r/w  | r/w       | r/w  | r/w  | r/w  | r/w         | r/w  | r/w       | r/w  |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:12 **IC4F[3:0]**: Input capture 4 filter

Bits 11:10 **IC4PSC[1:0]**: Input capture 4 prescaler

Bits 9:8 **CC4S[1:0]**: Capture/Compare 4 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC4 channel is configured as output

01: CC4 channel is configured as input, IC4 is mapped on TI4

10: CC4 channel is configured as input, IC4 is mapped on TI3

11: CC4 channel is configured as input, IC4 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note: CC4S bits are writable only when the channel is OFF (CC4E = 0 in TIMx\_CCER).*

Bits 7:4 **IC3F[3:0]**: Input capture 3 filter

Bits 3:2 **IC3PSC[1:0]**: Input capture 3 prescaler

Bits 1:0 **CC3S[1:0]**: Capture/Compare 3 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC3 channel is configured as output

01: CC3 channel is configured as input, IC3 is mapped on TI3

10: CC3 channel is configured as input, IC3 is mapped on TI4

11: CC3 channel is configured as input, IC3 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note: CC3S bits are writable only when the channel is OFF (CC3E = 0 in TIMx\_CCER).*

### 31.4.10 TIMx capture/compare mode register 2 [alternate] (TIMx\_CCMR2) (x = 2 to 5)

Address offset: 0x1C

Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode.

**Output compare mode:**

|       |           |      |      |       |       |           |         |       |           |      |      |       |       |           |         |
|-------|-----------|------|------|-------|-------|-----------|---------|-------|-----------|------|------|-------|-------|-----------|---------|
| 31    | 30        | 29   | 28   | 27    | 26    | 25        | 24      | 23    | 22        | 21   | 20   | 19    | 18    | 17        | 16      |
| Res.  | Res.      | Res. | Res. | Res.  | Res.  | Res.      | OC4M[3] | Res.  | Res.      | Res. | Res. | Res.  | Res.  | Res.      | OC3M[3] |
|       |           |      |      |       |       |           | rw      |       |           |      |      |       |       |           | rw      |
| 15    | 14        | 13   | 12   | 11    | 10    | 9         | 8       | 7     | 6         | 5    | 4    | 3     | 2     | 1         | 0       |
| OC4CE | OC4M[2:0] |      |      | OC4PE | OC4FE | CC4S[1:0] |         | OC3CE | OC3M[2:0] |      |      | OC3PE | OC3FE | CC3S[1:0] |         |
| rw    | rw        | rw   | rw   | rw    | rw    | rw        | rw      | rw    | rw        | rw   | rw   | rw    | rw    | rw        | rw      |

Bits 31:25 Reserved, must be kept at reset value.

Bits 23:17 Reserved, must be kept at reset value.

Bit 15 **OC4CE**: Output compare 4 clear enable

Bits 24, 14:12 **OC4M[3:0]**: Output compare 4 mode

Refer to OC1M description (bits 6:4 in TIMx\_CCMR1 register)

Bit 11 **OC4PE**: Output compare 4 preload enable

Bit 10 **OC4FE**: Output compare 4 fast enable

Bits 9:8 **CC4S[1:0]**: Capture/Compare 4 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC4 channel is configured as output

01: CC4 channel is configured as input, IC4 is mapped on TI4

10: CC4 channel is configured as input, IC4 is mapped on TI3

11: CC4 channel is configured as input, IC4 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note: CC4S bits are writable only when the channel is OFF (CC4E = 0 in TIMx\_CCER).*

Bit 7 **OC3CE**: Output compare 3 clear enable

Bits 16, 6:4 **OC3M[3:0]**: Output compare 3 mode

Refer to OC1M description (bits 6:4 in TIMx\_CCMR1 register)

Bit 3 **OC3PE**: Output compare 3 preload enable

Bit 2 **OC3FE**: Output compare 3 fast enable

Bits 1:0 **CC3S[1:0]**: Capture/Compare 3 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC3 channel is configured as output

01: CC3 channel is configured as input, IC3 is mapped on TI3

10: CC3 channel is configured as input, IC3 is mapped on TI4

11: CC3 channel is configured as input, IC3 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note: CC3S bits are writable only when the channel is OFF (CC3E = 0 in TIMx\_CCER).*

### 31.4.11 TIMx capture/compare enable register (TIMx\_CCER)(x = 2 to 5)

Address offset: 0x20

Reset value: 0x0000

| 15    | 14   | 13   | 12   | 11    | 10   | 9    | 8    | 7     | 6    | 5    | 4    | 3     | 2    | 1    | 0    |
|-------|------|------|------|-------|------|------|------|-------|------|------|------|-------|------|------|------|
| CC4NP | Res. | CC4P | CC4E | CC3NP | Res. | CC3P | CC3E | CC2NP | Res. | CC2P | CC2E | CC1NP | Res. | CC1P | CC1E |
| rw    |      | rw   | rw   | rw    |      | rw   | rw   | rw    |      | rw   | rw   | rw    |      | rw   | rw   |

Bit 15 **CC4NP**: Capture/Compare 4 output Polarity.

Refer to CC1NP description

Bit 14 Reserved, must be kept at reset value.

Bit 13 **CC4P**: Capture/Compare 4 output Polarity.

Refer to CC1P description

Bit 12 **CC4E**: Capture/Compare 4 output enable.

refer to CC1E description

Bit 11 **CC3NP**: Capture/Compare 3 output Polarity.

Refer to CC1NP description

Bit 10 Reserved, must be kept at reset value.

Bit 9 **CC3P**: Capture/Compare 3 output Polarity.

Refer to CC1P description

Bit 8 **CC3E**: Capture/Compare 3 output enable.

Refer to CC1E description

Bit 7 **CC2NP**: *Capture/Compare 2 output Polarity.*

Refer to CC1NP description

Bit 6 Reserved, must be kept at reset value.

Bit 5 **CC2P**: *Capture/Compare 2 output Polarity.*

refer to CC1P description

Bit 4 **CC2E**: *Capture/Compare 2 output enable.*

Refer to CC1E description

Bit 3 **CC1NP**: *Capture/Compare 1 output Polarity.*

**CC1 channel configured as output**: CC1NP must be kept cleared in this case.

**CC1 channel configured as input**: This bit is used in conjunction with CC1P to define TI1FP1/TI2FP1 polarity. refer to CC1P description.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **CC1P**: *Capture/Compare 1 output Polarity.*

0: OC1 active high (output mode) / Edge sensitivity selection (input mode, see below)

1: OC1 active low (output mode) / Edge sensitivity selection (input mode, see below)

**When CC1 channel is configured as input**, both CC1NP/CC1P bits select the active polarity of TI1FP1 and TI2FP1 for trigger or capture operations.

CC1NP=0, CC1P=0: non-inverted/rising edge. The circuit is sensitive to TIxFP1 rising edge (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger operation in gated mode or encoder mode).

CC1NP=0, CC1P=1: inverted/falling edge. The circuit is sensitive to TIxFP1 falling edge (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is inverted (trigger operation in gated mode or encoder mode).

CC1NP=1, CC1P=1: non-inverted/both edges. The circuit is sensitive to both TIxFP1 rising and falling edges (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger operation in gated mode). This configuration must not be used in encoder mode.

CC1NP=1, CC1P=0: This configuration is reserved, it must not be used.

Bit 0 **CC1E**: *Capture/Compare 1 output enable.*

0: Capture mode disabled / OC1 is not active

1: Capture mode enabled / OC1 signal is output on the corresponding output pin

**Table 204. Output control bit for standard OCx channels**

| CCxE bit | OCx output state                                 |
|----------|--------------------------------------------------|
| 0        | Output disabled (not driven by the timer: Hi-Z)  |
| 1        | Output enabled (tim_ocx = tim_ocxref + Polarity) |

*Note:* The state of the external IO pins connected to the standard OCx channels depends on the OCx channel state and the GPIO control and alternate function registers.

### 31.4.12 TIMx counter (TIMx\_CNT)(x = 2 to 5)

Bit 31 of this register has two possible definitions depending on the value of UIFREMAP in TIMx\_CR1 register:

- This section is for UIFREMAP = 0
- Next section is for UIFREMAP = 1

Address offset: 0x24

Reset value: 0x0000 0000

|            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31         | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| CNT[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW         | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |
| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| CNT[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW         | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 31:16 **CNT[31:16]**: Most significant part counter value (TIM2 and TIM5)Bits 15:0 **CNT[15:0]**: Least significant part of counter value

### 31.4.13 TIMx counter [alternate] (TIMx\_CNT)(x = 2 to 5)

Bit 31 of this register has two possible definitions depending on the value of UIFREMAP in TIMx\_CR1 register:

- Previous section is for UIFREMAP = 0
- This section is for UIFREMAP = 1

Address offset: 0x24

Reset value: 0x0000 0000

|           |            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----------|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31        | 30         | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| UIFCPY    | CNT[30:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW        | rW         | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |
| 15        | 14         | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| CNT[15:0] |            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW        | rW         | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bit 31 **UIFCPY**: UIF Copy

This bit is a read-only copy of the UIF bit of the TIMx\_ISR register

Bits 30:16 **CNT[30:16]**: Most significant part counter value (TIM2 and TIM5)Bits 15:0 **CNT[15:0]**: Least significant part of counter value

### 31.4.14 TIMx prescaler (TIMx\_PSC)(x = 2 to 5)

Address offset: 0x28

Reset value: 0x0000

|           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 15        | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| PSC[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW        | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 15:0 **PSC[15:0]**: Prescaler value

The counter clock frequency  $CK\_CNT$  is equal to  $f_{CK\_PSC} / (PSC[15:0] + 1)$ .

PSC contains the value to be loaded in the active prescaler register at each update event (including when the counter is cleared through UG bit of TIMx\_EGR register or through trigger controller when configured in “reset mode”).

### 31.4.15 TIMx auto-reload register (TIMx\_ARR)(x = 2 to 5)

Address offset: 0x2C

Reset value: 0xFFFF FFFF

|            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31         | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| ARR[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW         | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |
| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| ARR[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW         | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 31:16 **ARR[31:16]**: High auto-reload value (TIM2 and TIM5)

Bits 15:0 **ARR[15:0]**: Low Auto-reload value

ARR is the value to be loaded in the actual auto-reload register.

Refer to the [Section 31.3.1: Time-base unit on page 1003](#) for more details about ARR update and behavior.

The counter is blocked while the auto-reload value is null.

### 31.4.16 TIMx capture/compare register 1 (TIMx\_CCR1)(x = 2 to 5)

Address offset: 0x34

Reset value: 0x0000 0000

|             |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31          | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| CCR1[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW          | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |
| 15          | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| CCR1[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW          | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 31:16 **CCR1[31:16]**: High Capture/Compare 1 value (TIM2 and TIM5)

Bits 15:0 **CCR1[15:0]**: Low Capture/Compare 1 value

**If channel CC1 is configured as output:**

CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIMx\_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx\_CNT and signaled on OC1 output.

**If channel CC1 is configured as input:**

CCR1 is the counter value transferred by the last input capture 1 event (IC1). The TIMx\_CCR1 register is read-only and cannot be programmed.

### 31.4.17 TIMx capture/compare register 2 (TIMx\_CCR2)(x = 2 to 5)

Address offset: 0x38

Reset value: 0x0000 0000

|             |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31          | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| CCR2[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw          | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
| 15          | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| CCR2[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw          | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:16 **CCR2[31:16]**: High Capture/Compare 2 value (TIM2 and TIM5)

Bits 15:0 **CCR2[15:0]**: Low Capture/Compare 2 value

**If channel CC2 is configured as output:**

CCR2 is the value to be loaded in the actual capture/compare 2 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIMx\_CCMR1 register (bit OC2PE). Else the preload value is copied in the active capture/compare 2 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx\_CNT and signalled on OC2 output.

**If channel CC2 is configured as input:**

CCR2 is the counter value transferred by the last input capture 2 event (IC2). The TIMx\_CCR2 register is read-only and cannot be programmed.

### 31.4.18 TIMx capture/compare register 3 (TIMx\_CCR3)(x = 2 to 5)

Address offset: 0x3C

Reset value: 0x0000 0000

|             |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31          | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| CCR3[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW          | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |
| 15          | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| CCR3[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW          | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 31:16 **CCR3[31:16]**: High Capture/Compare 3 value (TIM2 and TIM5)

Bits 15:0 **CCR3[15:0]**: Low Capture/Compare value

**If channel CC3 is configured as output:**

CCR3 is the value to be loaded in the actual capture/compare 3 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIMx\_CCMR2 register (bit OC3PE). Else the preload value is copied in the active capture/compare 3 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx\_CNT and signalled on OC3 output.

**If channel CC3 is configured as input:**

CCR3 is the counter value transferred by the last input capture 3 event (IC3). The TIMx\_CCR3 register is read-only and cannot be programmed.

### 31.4.19 TIMx capture/compare register 4 (TIMx\_CCR4)(x = 2 to 5)

Address offset: 0x40

Reset value: 0x0000 0000

|             |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31          | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| CCR4[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

Bits 31:16 **CCR4[31:16]**: High Capture/Compare 4 value (TIM2 and TIM5)

Bits 15:0 **CCR4[15:0]**: Low Capture/Compare value

- if CC4 channel is configured as output (CC4S bits):  
CCR4 is the value to be loaded in the actual capture/compare 4 register (preload value). It is loaded permanently if the preload feature is not selected in the TIMx\_CCMR2 register (bit OC4PE). Else the preload value is copied in the active capture/compare 4 register when an update event occurs.  
The active capture/compare register contains the value to be compared to the counter TIMx\_CNT and signalled on OC4 output.
- if CC4 channel is configured as input (CC4S bits in TIMx\_CCMR4 register):  
CCR4 is the counter value transferred by the last input capture 4 event (IC4). The TIMx\_CCR4 register is read-only and cannot be programmed.

**31.4.20 TIMx DMA control register (TIMx\_DCR)(x = 2 to 5)**

Address offset: 0x48

Reset value: 0x0000

| 15   | 14   | 13   | 12       | 11 | 10 | 9  | 8  | 7    | 6    | 5    | 4        | 3  | 2  | 1  | 0  |
|------|------|------|----------|----|----|----|----|------|------|------|----------|----|----|----|----|
| Res. | Res. | Res. | DBL[4:0] |    |    |    |    | Res. | Res. | Res. | DBA[4:0] |    |    |    |    |
|      |      |      | rw       | rw | rw | rw | rw |      |      |      | rw       | rw | rw | rw | rw |

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:8 **DBL[4:0]**: DMA burst length

This 5-bit vector defines the number of DMA transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIMx\_DMAR address).

00000: 1 transfer,

00001: 2 transfers,

00010: 3 transfers,

...

10001: 18 transfers.

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **DBA[4:0]**: DMA base address

This 5-bit vector defines the base-address for DMA transfers (when read/write access are done through the TIMx\_DMAR address). DBA is defined as an offset starting from the address of the TIMx\_CR1 register.

Example:

00000: TIMx\_CR1

00001: TIMx\_CR2

00010: TIMx\_SMCR

...

**Example:** Let us consider the following transfer: DBL = 7 transfers & DBA = TIMx\_CR1. In this case the transfer is done to/from 7 registers starting from the TIMx\_CR1 address.

**31.4.21 TIMx DMA address for full transfer (TIMx\_DMAR)(x = 2 to 5)**

Address offset: 0x4C

Reset value: 0x0000

| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| DMAB[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw         | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 15:0 **DMAB[15:0]**: DMA register for burst accesses

A read or write operation to the DMAR register accesses the register located at the address  
 $(\text{TIMx\_CR1 address}) + (\text{DBA} + \text{DMA index}) \times 4$

where TIMx\_CR1 address is the address of the control register 1, DBA is the DMA base address configured in TIMx\_DCR register, DMA index is automatically controlled by the DMA transfer, and ranges from 0 to DBL (DBL configured in TIMx\_DCR).

**31.4.22 TIM2 option register 1 (TIM2\_OR1)**

Address offset: 0x50

## 32 General-purpose timers (TIM15/TIM16/TIM17)

### 32.1 TIM15/TIM16/TIM17 introduction

The TIM15/TIM16/TIM17 timers consist of a 16-bit auto-reload counter driven by a programmable prescaler.

They may be used for a variety of purposes, including measuring the pulse lengths of input signals (input capture) or generating output waveforms (output compare, PWM, complementary PWM with dead-time insertion).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The TIM15/TIM16/TIM17 timers are completely independent, and do not share any resources. TIM15 can be synchronized as described in [Section 32.5.22: Timer synchronization \(TIM15\)](#).

### 32.2 TIM15 main features

TIM15 includes the following features:

- 16-bit auto-reload upcounter
- 16-bit programmable prescaler used to divide (also “on the fly”) the counter clock frequency by any factor between 1 and 65535
- Up to 2 independent channels for:
  - Input capture
  - Output compare
  - PWM generation (edge mode)
  - One-pulse mode output
- Complementary outputs with programmable dead-time (for channel 1 only)
- Synchronization circuit to control the timer with external signals and to interconnect several timers together
- Repetition counter to update the timer registers only after a given number of cycles of the counter
- Break input to put the timer’s output signals in the reset state or a known state
- Interrupt/DMA generation on the following events:
  - Update: counter overflow, counter initialization (by software or internal/external trigger)
  - Trigger event (counter start, stop, initialization or count by internal/external trigger)
  - Input capture
  - Output compare
  - Break input (interrupt request)

### 32.3 TIM16/TIM17 main features

The TIM16/TIM17 timers include the following features:

- 16-bit auto-reload upcounter
- 16-bit programmable prescaler used to divide (also “on the fly”) the counter clock frequency by any factor between 1 and 65535
- One channel for:
  - Input capture
  - Output compare
  - PWM generation (edge-aligned mode)
  - One-pulse mode output
- Complementary outputs with programmable dead-time
- Repetition counter to update the timer registers only after a given number of cycles of the counter
- Break input to put the timer’s output signals in the reset state or a known state
- Interrupt/DMA generation on the following events:
  - Update: counter overflow
  - Input capture
  - Output compare
  - Break input

Figure 334. TIM15 block diagram

- The internal break event source can be:
  - A clock failure event generated by CSS. For further information on the CSS, refer to [Section 6.2.10: Clock security system \(CSS\)](#)
  - A PVD output
  - SRAM parity error signal
  - Cortex<sup>®</sup>-M4 LOCKUP (Hardfault) output
  - COMP output

## 32.5 TIM15/TIM16/TIM17 functional description

### 32.5.1 Time-base unit

The main block of the programmable advanced-control timer is a 16-bit upcounter with its related auto-reload register. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:

- Counter register (TIMx\_CNT)
- Prescaler register (TIMx\_PSC)
- Auto-reload register (TIMx\_ARR)
- Repetition counter register (TIMx\_RCR)

The auto-reload register is preloaded. Writing to or reading from the auto-reload register accesses the preload register. The content of the preload register are transferred into the shadow register permanently or at each update event (UEV), depending on the auto-reload preload enable bit (ARPE) in TIMx\_CR1 register. The update event is sent when the counter reaches the overflow and if the UDIS bit equals 0 in the TIMx\_CR1 register. It can also be generated by software. The generation of the update event is described in detailed for each configuration.

The counter is clocked by the prescaler output CK\_CNT, which is enabled only when the counter enable bit (CEN) in TIMx\_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

Note that the counter starts counting 1 clock cycle after setting the CEN bit in the TIMx\_CR1 register.

#### Prescaler description

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx\_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

*Figure 336* and *Figure 337* give some examples of the counter behavior when the prescaler ratio is changed on the fly:

Figure 336. Counter timing diagram with prescaler division change from 1 to 2

Figure 337. Counter timing diagram with prescaler division change from 1 to 4

## 32.5.2 Counter modes

### Upcounting mode

In upcounting mode, the counter counts from 0 to the auto-reload value (content of the TIMx\_ARR register), then restarts from 0 and generates a counter overflow event.

If the repetition counter is used, the update event (UEV) is generated after upcounting is repeated for the number of times programmed in the repetition counter register (TIMx\_RCR). Else the update event is generated at each counter overflow.

Setting the UG bit in the TIMx\_EGR register (by software or by using the slave mode controller) also generates an update event.

The UEV event can be disabled by software by setting the UDIS bit in the TIMx\_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIMx\_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx\_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx\_RCR register,
- The auto-reload shadow register is updated with the preload value (TIMx\_ARR),
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx\_PSC register).

The following figures show some examples of the counter behavior for different clock frequencies when TIMx\_ARR=0x36.

Figure 338. Counter timing diagram, internal clock divided by 1

Figure 339. Counter timing diagram, internal clock divided by 2

Figure 340. Counter timing diagram, internal clock divided by 4

Figure 341. Counter timing diagram, internal clock divided by N

**Figure 342. Counter timing diagram, update event when ARPE=0 (TIMx\_ARR not preloaded)**

**Figure 343. Counter timing diagram, update event when ARPE=1 (TIMx\_ARR preloaded)**

### 32.5.3 Repetition counter

[Section 32.5.1: Time-base unit](#) describes how the update event (UEV) is generated with respect to the counter overflows. It is actually generated only when the repetition counter has reached zero. This can be useful when generating PWM signals.

This means that data are transferred from the preload registers to the shadow registers (TIMx\_ARR auto-reload register, TIMx\_PSC prescaler register, but also TIMx\_CCRx capture/compare registers in compare mode) every N counter overflows, where N is the value in the TIMx\_RCR repetition counter register.

The repetition counter is decremented at each counter overflow.

The repetition counter is an auto-reload type; the repetition rate is maintained as defined by the TIMx\_RCR register value (refer to [Figure 344](#)). When the update event is generated by software (by setting the UG bit in TIMx\_EGR register) or by hardware through the slave mode controller, it occurs immediately whatever the value of the repetition counter is and the repetition counter is reloaded with the content of the TIMx\_RCR register.

**Figure 344. Update rate examples depending on mode and TIMx\_RCR register settings**

### 32.5.4 Clock selection

The counter clock can be provided by the following clock sources:

- Internal clock (CK\_INT)
- External clock mode1: external input pin
- Internal trigger inputs (ITRx) (only for TIM15): using one timer as the prescaler for another timer, for example, TIM1 can be configured to act as a prescaler for TIM15. Refer to [Using one timer as prescaler for another timer on page 1041](#) for more details.

#### Internal clock source (CK\_INT)

If the slave mode controller is disabled (SMS=000), then the CEN (in the TIMx\_CR1 register) and UG bits (in the TIMx\_EGR register) are actual control bits and can be changed

only by software (except UG which remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock CK\_INT.

Figure 345 shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.

**Figure 345. Control circuit in normal mode, internal clock divided by 1**

### External clock source mode 1

This mode is selected when SMS=111 in the TIMx\_SMCR register. The counter can count at each rising or falling edge on a selected input.

**Figure 346. TI2 external clock connection example**

For example, to configure the upcounter to count in response to a rising edge on the TI2 input, use the following procedure:

1. Configure channel 2 to detect rising edges on the TI2 input by writing CC2S = '01' in the TIMx\_CCMR1 register.
2. Configure the input filter duration by writing the IC2F[3:0] bits in the TIMx\_CCMR1 register (if no filter is needed, keep IC2F=0000).
3. Select rising edge polarity by writing CC2P=0 in the TIMx\_CCER register.
4. Configure the timer in external clock mode 1 by writing SMS=111 in the TIMx\_SMCR register.
5. Select TI2 as the trigger input source by writing TS=110 in the TIMx\_SMCR register.
6. Enable the counter by writing CEN=1 in the TIMx\_CR1 register.

**Note:** *The capture prescaler is not used for triggering, so it does not need to be configured.*

When a rising edge occurs on TI2, the counter counts once and the TIF flag is set.

The delay between the rising edge on TI2 and the actual clock of the counter is due to the resynchronization circuit on TI2 input.

**Figure 347. Control circuit in external clock mode 1**

### 32.5.5 Capture/compare channels

Each Capture/Compare channel is built around a capture/compare register (including a shadow register), a input stage for capture (with digital filter, multiplexing and prescaler) and an output stage (with comparator and output control).

[Figure 348](#) to [Figure 351](#) give an overview of one Capture/Compare channel.

The input stage samples the corresponding TIx input to generate a filtered signal TIxF. Then, an edge detector with polarity selection generates a signal (TIxFPx) which can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (ICxPS).

Figure 348. Capture/compare channel (example: channel 1 input stage)

MS31088V2

The output stage generates an intermediate waveform which is then used for reference: OCxRef (active high). The polarity acts at the end of the chain.

Figure 350. Output stage of capture/compare channel (channel 1)

Figure 351. Output stage of capture/compare channel (channel 2 for TIM15)

The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register.

In capture mode, captures are actually done in the shadow register, which is copied into the preload register.

In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

### 32.5.6 Input capture mode

In Input capture mode, the Capture/Compare registers (TIMx\_CCRx) are used to latch the value of the counter after a transition detected by the corresponding ICx signal. When a capture occurs, the corresponding CCxIF flag (TIMx\_SR register) is set and an interrupt or a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was

already high, then the over-capture flag CCxOF (TIMx\_SR register) is set. CCxIF can be cleared by software by writing it to '0' or by reading the captured data stored in the TIMx\_CCRx register. CCxOF is cleared when it is written with 0.

The following example shows how to capture the counter value in TIMx\_CCR1 when TI1 input rises. To do this, use the following procedure:

1. Select the active input: TIMx\_CCR1 must be linked to the TI1 input, so write the CC1S bits to 01 in the TIMx\_CCMR1 register. As soon as CC1S becomes different from 00, the channel is configured in input and the TIMx\_CCR1 register becomes read-only.
2. Program the appropriate input filter duration in relation with the signal connected to the timer (when the input is one of the TIx (ICxF bits in the TIMx\_CCMRx register). Let's imagine that, when toggling, the input signal is not stable during at least 5 internal clock cycles. We must program a filter duration longer than these 5 clock cycles. We can validate a transition on TI1 when 8 consecutive samples with the new level have been detected (sampled at  $f_{DTS}$  frequency). Then write IC1F bits to 0011 in the TIMx\_CCMR1 register.
3. Select the edge of the active transition on the TI1 channel by writing CC1P bit to 0 in the TIMx\_CCER register (rising edge in this case).
4. Program the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to '00' in the TIMx\_CCMR1 register).
5. Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx\_CCER register.
6. If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx\_DIER register, and/or the DMA request by setting the CC1DE bit in the TIMx\_DIER register.

When an input capture occurs:

- The TIMx\_CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.
- A DMA request is generated depending on the CC1DE bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which could happen after reading the flag and before reading the data.

*Note:* IC interrupt and/or DMA requests can be generated by software by setting the corresponding CCxG bit in the TIMx\_EGR register.

### 32.5.7 PWM input mode (only for TIM15)

This mode is a particular case of input capture mode. The procedure is the same except:

- Two ICx signals are mapped on the same TIx input.
- These 2 ICx signals are active on edges with opposite polarity.
- One of the two TIxFP signals is selected as trigger input and the slave mode controller is configured in reset mode.

For example, one can measure the period (in TIMx\_CCR1 register) and the duty cycle (in TIMx\_CCR2 register) of the PWM applied on TI1 using the following procedure (depending on CK\_INT frequency and prescaler value):

1. Select the active input for TIMx\_CCR1: write the CC1S bits to 01 in the TIMx\_CCMR1 register (TI1 selected).
2. Select the active polarity for TI1FP1 (used both for capture in TIMx\_CCR1 and counter clear): write the CC1P and CC1NP bits to '0' (active on rising edge).
3. Select the active input for TIMx\_CCR2: write the CC2S bits to 10 in the TIMx\_CCMR1 register (TI1 selected).
4. Select the active polarity for TI1FP2 (used for capture in TIMx\_CCR2): write the CC2P and CC2NP bits to '10' (active on falling edge).
5. Select the valid trigger input: write the TS bits to 101 in the TIMx\_SMCR register (TI1FP1 selected).
6. Configure the slave mode controller in reset mode: write the SMS bits to 100 in the TIMx\_SMCR register.
7. Enable the captures: write the CC1E and CC2E bits to '1' in the TIMx\_CCER register.

Figure 352. PWM input mode timing

1. The PWM input mode can be used only with the TIMx\_CH1/TIMx\_CH2 signals due to the fact that only TI1FP1 and TI2FP2 are connected to the slave mode controller.

### 32.5.8 Forced output mode

In output mode (CCxS bits = 00 in the TIMx\_CCMRx register), each output compare signal (OCxREF and then OCx/OCxN) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (OCxREF/OCx) to its active level, one just needs to write 101 in the OCxM bits in the corresponding TIMx\_CCMRx register. Thus OCxREF is forced high (OCxREF is always active high) and OCx get opposite value to CCxP polarity bit.

For example: CCxP=0 (OCx active high) => OCx is forced to high level.

The OCxREF signal can be forced low by writing the OCxM bits to 100 in the TIMx\_CCMRx register.

Anyway, the comparison between the TIMx\_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt and DMA requests can be sent accordingly. This is described in the output compare mode section below.

### 32.5.9 Output compare mode

This function is used to control an output waveform or indicating when a period of time has elapsed.

When a match is found between the capture/compare register and the counter, the output compare function:

- Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx\_CCMRx register) and the output polarity (CCxP bit in the TIMx\_CCER register). The output pin can keep its level (OCxM=000), be set active (OCxM=001), be set inactive (OCxM=010) or can toggle (OCxM=011) on match.
- Sets a flag in the interrupt status register (CCxIF bit in the TIMx\_SR register).
- Generates an interrupt if the corresponding interrupt mask is set (CCXIE bit in the TIMx\_DIER register).
- Sends a DMA request if the corresponding enable bit is set (CCxDE bit in the TIMx\_DIER register, CCDS bit in the TIMx\_CR2 register for the DMA request selection).

The TIMx\_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx\_CCMRx register.

In output compare mode, the update event UEV has no effect on OCxREF and OCx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One-pulse mode).

#### Procedure

1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx\_ARR and TIMx\_CCRx registers.
3. Set the CCXIE bit if an interrupt request is to be generated.
4. Select the output mode. For example:
  - Write OCxM = 011 to toggle OCx output pin when CNT matches CCRx
  - Write OCxPE = 0 to disable preload register
  - Write CCxP = 0 to select active high polarity
  - Write CCxE = 1 to enable the output
5. Enable the counter by setting the CEN bit in the TIMx\_CR1 register.

The TIMx\_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE='0', else TIMx\_CCRx shadow register is updated only at the next update event UEV). An example is given in [Figure 353](#).

Figure 353. Output compare mode, toggle on OC1

### 32.5.10 PWM mode

Pulse Width Modulation mode allows a signal to be generated with a frequency determined by the value of the TIMx\_ARR register and a duty cycle determined by the value of the TIMx\_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per OCx output) by writing '110' (PWM mode 1) or '111' (PWM mode 2) in the OCxM bits in the TIMx\_CCMRx register. The corresponding preload register must be enabled by setting the OCxPE bit in the TIMx\_CCMRx register, and eventually the auto-reload preload register (in upcounting or center-aligned modes) by setting the ARPE bit in the TIMx\_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, all registers must be initialized by setting the UG bit in the TIMx\_EGR register.

OCx polarity is software programmable using the CCxP bit in the TIMx\_CCER register. It can be programmed as active high or active low. OCx output is enabled by a combination of the CCxE, CCxNE, MOE, OSSI and OSSR bits (TIMx\_CCER and TIMx\_BDTR registers). Refer to the TIMx\_CCER register description for more details.

In PWM mode (1 or 2), TIMx\_CNT and TIMx\_CCRx are always compared to determine whether  $TIMx\_CCRx \leq TIMx\_CNT$  or  $TIMx\_CNT \leq TIMx\_CCRx$  (depending on the direction of the counter).

The TIM15/TIM16/TIM17 are capable of upcounting only. Refer to [Upcounting mode on page 1080](#).

In the following example, we consider PWM mode 1. The reference PWM signal OCxREF is high as long as  $TIMx\_CNT < TIMx\_CCRx$  else it becomes low. If the compare value in TIMx\_CCRx is greater than the auto-reload value (in TIMx\_ARR) then OCxREF is held at

'1'. If the compare value is 0 then OCxRef is held at '0'. [Figure 354](#) shows some edge-aligned PWM waveforms in an example where TIMx\_ARR=8.

**Figure 354. Edge-aligned PWM waveforms (ARR=8)**

### 32.5.11 Combined PWM mode (TIM15 only)

Combined PWM mode allows two edge or center-aligned PWM signals to be generated with programmable delay and phase shift between respective pulses. While the frequency is determined by the value of the TIMx\_ARR register, the duty cycle and delay are determined by the two TIMx\_CCRx registers. The resulting signals, OCxREFC, are made of an OR or AND logical combination of two reference PWMs:

- OC1REFC (or OC2REFC) is controlled by the TIMx\_CCR1 and TIMx\_CCR2 registers

Combined PWM mode can be selected independently on two channels (one OCx output per pair of CCR registers) by writing '1100' (Combined PWM mode 1) or '1101' (Combined PWM mode 2) in the OCxM bits in the TIMx\_CCMRx register.

When a given channel is used as a combined PWM channel, its complementary channel must be configured in the opposite PWM mode (for instance, one in Combined PWM mode 1 and the other in Combined PWM mode 2).

**Note:** The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

[Figure 355](#) represents an example of signals that can be generated using Asymmetric PWM mode, obtained with the following configuration:

- Channel 1 is configured in Combined PWM mode 2,
- Channel 2 is configured in PWM mode 1,

Figure 355. Combined PWM mode on channel 1 and 2

### 32.5.12 Complementary outputs and dead-time insertion

The TIM15/TIM16/TIM17 general-purpose timers can output one complementary signal and manage the switching-off and switching-on of the outputs.

This time is generally known as dead-time and it has to be adjusted depending on the devices that are connected to the outputs and their characteristics (intrinsic delays of level-shifters, delays due to power switches...)

The polarity of the outputs (main output OCx or complementary OCxN) can be selected independently for each output. This is done by writing to the CCxP and CCxNP bits in the TIMx\_CCER register.

The complementary signals OCx and OCxN are activated by a combination of several control bits: the CCxE and CCxNE bits in the TIMx\_CCER register and the MOE, OISx, OISxN, OSSI and OSSR bits in the TIMx\_BDTR and TIMx\_CR2 registers. Refer to [Table 209: Output control bits for complementary OCx and OCxN channels with break feature \(TIM16/17\) on page 1147](#) for more details. In particular, the dead-time is activated when switching to the idle state (MOE falling down to 0).

Dead-time insertion is enabled by setting both CCxE and CCxNE bits, and the MOE bit if the break circuit is present. There is one 10-bit dead-time generator for each channel. From a

reference waveform OCxREF, it generates 2 outputs OCx and OCxN. If OCx and OCxN are active high:

- The OCx output signal is the same as the reference signal except for the rising edge, which is delayed relative to the reference rising edge.
- The OCxN output signal is the opposite of the reference signal except for the rising edge, which is delayed relative to the reference falling edge.

If the delay is greater than the width of the active output (OCx or OCxN) then the corresponding pulse is not generated.

The following figures show the relationships between the output signals of the dead-time generator and the reference signal OCxREF. (we suppose CCxP=0, CCxNP=0, MOE=1, CCxE=1 and CCxNE=1 in these examples)

**Figure 356. Complementary output with dead-time insertion.**

**Figure 357. Dead-time waveforms with delay greater than the negative pulse.**

**Figure 358. Dead-time waveforms with delay greater than the positive pulse.**

The dead-time delay is the same for each of the channels and is programmable with the DTG bits in the TIMx\_BDTR register. Refer to [Section 32.7.14: TIMx break and dead-time register \(TIMx\\_BDTR\)\(x = 16 to 17\) on page 1150](#) for delay calculation.

### Re-directing OCxREF to OCx or OCxN

In output mode (forced, output compare or PWM), OCxREF can be re-directed to the OCx output or to OCxN output by configuring the CCxE and CCxNE bits in the TIMx\_CCER register.

This allows a specific waveform to be sent (such as PWM or static active level) on one output while the complementary remains at its inactive level. Other alternative possibilities are to have both outputs at inactive level or both outputs active and complementary with dead-time.

**Note:** *When only OCxN is enabled (CCxE=0, CCxNE=1), it is not complemented and becomes active as soon as OCxREF is high. For example, if CCxNP=0 then OCxN=OCxRef. On the other hand, when both OCx and OCxN are enabled (CCxE=CCxNE=1) OCx becomes active when OCxREF is high whereas OCxN is complemented and becomes active when OCxREF is low.*

### 32.5.13 Using the break function

The purpose of the break function is to protect power switches driven by PWM signals generated with the TIM15/TIM16/TIM17 timers. The break input is usually connected to fault outputs of power stages and 3-phase inverters. When activated, the break circuitry shuts down the PWM outputs and forces them to a predefined safe state.

The break channel gathers both system-level fault (clock failure, parity error,...) and application fault (from input pins and built-in comparator), and can force the outputs to a predefined level (either active or inactive) after a deadtime duration.

The output enable signal and output levels during break are depending on several control bits:

- the MOE bit in TIMx\_BDTR register allows to enable /disable the outputs by software and is reset in case of break event.
- the OSSR bit in the TIMx\_BDTR register defines whether the timer controls the output in inactive state or releases the control to the GPIO controller (typically to have it in Hi-Z mode)
- the OISx and OISxN bits in the TIMx\_CR2 register which are setting the output shut-down level, either active or inactive. The OCx and OCxN outputs cannot be set both to active level at a given time, whatever the OISx and OISxN values. Refer to [Table 207: Output control bits for complementary OCx and OCxN channels with break feature \(TIM15\) on page 1126](#) for more details.

When exiting from reset, the break circuit is disabled and the MOE bit is low. The break function is enabled by setting the BKE bit in the TIMx\_BDTR register. The break input polarity can be selected by configuring the BKP bit in the same register. BKE and BKP can be modified at the same time. When the BKE and BKP bits are written, a delay of 1 APB clock cycle is applied before the writing is effective. Consequently, it is necessary to wait 1 APB clock period to correctly read back the bit after the write operation.

Because MOE falling edge can be asynchronous, a resynchronization circuit has been inserted between the actual signal (acting on the outputs) and the synchronous control bit (accessed in the TIMx\_BDTR register). It results in some delays between the asynchronous and the synchronous signals. In particular, if MOE is set to 1 whereas it was low, a delay must be inserted (dummy instruction) before reading it correctly. This is because the write acts on the asynchronous signal whereas the read reflects the synchronous signal.

The break can be generated from multiple sources which can be individually enabled and with programmable edge sensitivity, using the TIMx\_OR2 register.

The sources for break (BRK) channel are:

- An external source connected to one of the BKIN pin (as per selection done in the GPIO alternate function registers), with polarity selection and optional digital filtering
- An internal source:
  - the Cortex®-M4 LOCKUP output
  - the PVD output
  - the SRAM parity error signal
  - a flash ECC error
  - a clock failure event generated by the CSS detector
  - the output from a comparator, with polarity selection and optional digital filtering
  - the analog watchdog output of the DFSDM1 peripheral

Break events can also be generated by software using BG bit in the TIMx\_EGR register.

All sources are ORed before entering the timer BRK inputs, as per [Figure 359](#) below.

Figure 359. Break circuitry overview

When a break occurs (selected level on the break input):

- The MOE bit is cleared asynchronously, putting the outputs in inactive state, idle state or even releasing the control to the GPIO (selected by the OSS1 bit). This feature functions even if the MCU oscillator is off.
- Each output channel is driven with the level programmed in the OISx bit in the TIMx\_CR2 register as soon as MOE=0. If OSS1=0, the timer releases the output control (taken over by the GPIO) else the enable output remains high.
- When complementary outputs are used:
  - The outputs are first put in reset state inactive state (depending on the polarity). This is done asynchronously so that it works even if no clock is provided to the timer.
  - If the timer clock is still present, then the dead-time generator is reactivated in order to drive the outputs with the level programmed in the OISx and OISxN bits after a dead-time. Even in this case, OCx and OCxN cannot be driven to their

active level together. Note that because of the resynchronization on MOE, the dead-time duration is a bit longer than usual (around 2  $ck\_tim$  clock cycles).

- If OSSR=0 then the timer releases the enable outputs (taken over by the GPIO which forces a Hi-Z state) else the enable outputs remain or become high as soon as one of the CCxE or CCxNE bits is high.
- The break status flag (BIF bit in the TIMx\_SR register) is set. An interrupt can be generated if the BIE bit in the TIMx\_DIER register is set.
- If the AOE bit in the TIMx\_BDTR register is set, the MOE bit is automatically set again at the next update event UEV. This can be used to perform a regulation, for instance. Else, MOE remains low until it is written with 1 again. In this case, it can be used for security and the break input can be connected to an alarm from power drivers, thermal sensors or any security components.

*Note: If the MOE is reset by the CPU while the AOE bit is set, the outputs are in idle state and forced to inactive level or Hi-Z depending on OSSR value.  
If both the MOE and AOE bits are reset by the CPU, the outputs are in disabled state and driven with the level programmed in the OISx bit in the TIMx\_CR2 register.*

*Note: The break inputs is acting on level. Thus, the MOE cannot be set while the break input is active (neither automatically nor by software). In the meantime, the status flag BIF cannot be cleared.*

The break can be generated by the BRK input which has a programmable polarity and an enable bit BKE in the TIMx\_BDTR register.

In addition to the break input and the output management, a write protection has been implemented inside the break circuit to safeguard the application. It allows the configuration of several parameters to be frozen (dead-time duration, OCx/OCxN polarities and state when disabled, OCxM configurations, break enable and polarity). The protection can be selected among 3 levels with the LOCK bits in the TIMx\_BDTR register. Refer to [Section 32.7.14: TIMx break and dead-time register \(TIMx\\_BDTR\)\(x = 16 to 17\) on page 1150](#). The LOCK bits can be written only once after an MCU reset.

The [Figure 360](#) shows an example of behavior of the outputs in response to a break.

Figure 360. Output behavior in response to a break

### 32.5.14 6-step PWM generation

When complementary outputs are used on a channel, preload bits are available on the OCxM, CCxE and CCxNE bits. The preload bits are transferred to the shadow bits at the COM commutation event. Thus one can program in advance the configuration for the next step and change the configuration of all the channels at the same time. COM can be generated by software by setting the COM bit in the TIMx\_EGR register or by hardware (on tim\_trgi rising edge).

A flag is set when the COM event occurs (COMIF bit in the TIMx\_SR register), which can generate an interrupt (if the COMIE bit is set in the TIMx\_DIER register) or a DMA request (if the COMDE bit is set in the TIMx\_DIER register).

The [Figure 361](#) describes the behavior of the tim\_ocx and tim\_ocxn outputs when a COM event occurs, in 3 different examples of programmed configurations.

**Figure 361. 6-step generation, COM example (OSSR=1)**

### 32.5.15 One-pulse mode

One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. One-pulse mode is selected by setting the OPM bit in the TIMx\_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be:

- $CNT < CCRx \leq ARR$  (in particular,  $0 < CCRx$ )

**Figure 362. Example of one pulse mode**

For example one may want to generate a positive pulse on OC1 with a length of t<sub>PULSE</sub> and after a delay of t<sub>DELAY</sub> as soon as a positive edge is detected on the TI2 input pin.

Let's use TI2FP2 as trigger 1:

1. Map TI2FP2 to TI2 by writing CC2S='01' in the TIMx\_CCMR1 register.
2. TI2FP2 must detect a rising edge, write CC2P='0' and CC2NP='0' in the TIMx\_CCER register.
3. Configure TI2FP2 as trigger for the slave mode controller (TRGI) by writing TS='110' in the TIMx\_SMCR register.
4. TI2FP2 is used to start the counter by writing SMS to '110' in the TIMx\_SMCR register (trigger mode).

The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler).

- The  $t_{\text{DELAY}}$  is defined by the value written in the TIMx\_CCR1 register.
- The  $t_{\text{PULSE}}$  is defined by the difference between the auto-reload value and the compare value (TIMx\_ARR - TIMx\_CCR1).
- Let's say one want to build a waveform with a transition from '0' to '1' when a compare match occurs and a transition from '1' to '0' when the counter reaches the auto-reload value. To do this PWM mode 2 must be enabled by writing OC1M=111 in the TIMx\_CCMR1 register. Optionally the preload registers can be enabled by writing OC1PE='1' in the TIMx\_CCMR1 register and ARPE in the TIMx\_CR1 register. In this case one has to write the compare value in the TIMx\_CCR1 register, the auto-reload value in the TIMx\_ARR register, generate an update by setting the UG bit and wait for external trigger event on TI2. CC1P is written to '0' in this example.

Since only 1 pulse is needed, a 1 must be written in the OPM bit in the TIMx\_CR1 register to stop the counter at the next update event (when the counter rolls over from the auto-reload value back to 0).

Particular case: OCx fast enable

In One-pulse mode, the edge detection on TIx input set the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations and it limits the minimum delay  $t_{\text{DELAY}}$  min we can get.

If one wants to output a waveform with the minimum delay, the OCxFE bit can be set in the TIMx\_CCMRx register. Then OCxRef (and OCx) are forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

### 32.5.16 Retriggerable one pulse mode (TIM15 only)

This mode allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length, but with the following differences with Non-retriggerable one pulse mode described in [Section 32.5.15](#):

- The pulse starts as soon as the trigger occurs (no programmable delay)
- The pulse is extended if a new trigger occurs before the previous one is completed

The timer must be in Slave mode, with the bits SMS[3:0] = '1000' (Combined Reset + trigger mode) in the TIMx\_SMCR register, and the OCxM[3:0] bits set to '1000' or '1001' for Retriggerable OPM mode 1 or 2.

If the timer is configured in Up-counting mode, the corresponding CCRx must be set to 0 (the ARR register sets the pulse length). If the timer is configured in Down-counting mode, CCRx must be above or equal to ARR.

*Note: The OCxM[3:0] and SMS[3:0] bit fields are split into two parts for compatibility reasons, the most significant bit are not contiguous with the 3 least significant ones.*

*This mode must not be used with center-aligned PWM modes. It is mandatory to have CMS[1:0] = 00 in TIMx\_CR1.*

Figure 363. Retriggerable one pulse mode

### 32.5.17 UIF bit remapping

The IUFREMAP bit in the TIMx\_CR1 register forces a continuous copy of the Update Interrupt Flag UIF into bit 31 of the timer counter register (TIMxCNT[31]). This allows both the counter value and a potential roll-over condition signaled by the UIFCPY flag, to be atomically read. In particular cases, it can ease the calculations by avoiding race conditions caused for instance by a processing shared between a background task (counter reading) and an interrupt (Update Interrupt).

There is no latency between the assertions of the UIF and UIFCPY flags.

### 32.5.18 Timer input XOR function (TIM15 only)

The TI1S bit in the TIMx\_CR2 register, allows the input filter of channel 1 to be connected to the output of a XOR gate, combining the two input pins TIMx\_CH1 and TIMx\_CH2.

The XOR output can be used with all the timer input functions such as trigger or input capture. It is useful for measuring the interval between the edges on two input signals, as shown in [Figure 364](#).

**Figure 364. Measuring time interval between edges on 2 signals**

### 32.5.19 External trigger synchronization (TIM15 only)

The TIM timers are linked together internally for timer synchronization or chaining.

The TIM15 timer can be synchronized with an external trigger in several modes: Reset mode, Gated mode and Trigger mode.

#### Slave mode: Reset mode

The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIMx\_CR1 register is low, an update event UEV is generated. Then all the preloaded registers (TIMx\_ARR, TIMx\_CCRx) are updated.

In the following example, the upcounter is cleared in response to a rising edge on TI1 input:

1. Configure the channel 1 to detect rising edges on TI1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S = 01 in the TIMx\_CCMR1 register. Write CC1P='0' and CC1NP='0' in the TIMx\_CCER register to validate the polarity (and detect rising edges only).
2. Configure the timer in reset mode by writing SMS=100 in TIMx\_SMCR register. Select TI1 as the input source by writing TS=101 in TIMx\_SMCR register.
3. Start the counter by writing CEN=1 in the TIMx\_CR1 register.

The counter starts counting on the internal clock, then behaves normally until TI1 rising edge. When TI1 rises, the counter is cleared and restarts from 0. In the meantime, the trigger flag is set (TIF bit in the TIMx\_SR register) and an interrupt request, or a DMA request can be sent if enabled (depending on the TIE and TDE bits in TIMx\_DIER register).

The following figure shows this behavior when the auto-reload register TIMx\_ARR=0x36. The delay between the rising edge on TI1 and the actual reset of the counter is due to the resynchronization circuit on TI1 input.

**Figure 365. Control circuit in reset mode**

### Slave mode: Gated mode

The counter can be enabled depending on the level of a selected input.

In the following example, the upcounter counts only when TI1 input is low:

1. Configure the channel 1 to detect low levels on TI1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S=01 in TIMx\_CCMR1 register. Write CC1P=1 and CC1NP = '0' in the TIMx\_CCER register to validate the polarity (and detect low level only).
2. Configure the timer in gated mode by writing SMS=101 in TIMx\_SMCR register. Select TI1 as the input source by writing TS=101 in TIMx\_SMCR register.
3. Enable the counter by writing CEN=1 in the TIMx\_CR1 register (in gated mode, the counter doesn't start if CEN=0, whatever is the trigger input level).

The counter starts counting on the internal clock as long as TI1 is low and stops as soon as TI1 becomes high. The TIF flag in the TIMx\_SR register is set both when the counter starts or stops.

The delay between the rising edge on TI1 and the actual stop of the counter is due to the resynchronization circuit on TI1 input.

**Figure 366. Control circuit in gated mode**

### Slave mode: Trigger mode

The counter can start in response to an event on a selected input.

In the following example, the upcounter starts in response to a rising edge on TI2 input:

1. Configure the channel 2 to detect rising edges on TI2. Configure the input filter duration (in this example, we do not need any filter, so we keep IC2F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC2S bits are configured to select the input capture source only, CC2S=01 in TIMx\_CCMR1 register. Write CC2P='1' and CC2NP='0' in the TIMx\_CCER register to validate the polarity (and detect low level only).
2. Configure the timer in trigger mode by writing SMS=110 in the TIMx\_SMCR register. Select TI2 as the input source by writing TS=110 in the TIMx\_SMCR register.

When a rising edge occurs on TI2, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on TI2 and the actual start of the counter is due to the resynchronization circuit on TI2 input.

**Figure 367. Control circuit in trigger mode**

### 32.5.20 Slave mode – combined reset + trigger mode

In this case, a rising edge of the selected trigger input (TRGI) reinitializes the counter, generates an update of the registers, and starts the counter.

This mode is used for one-pulse mode.

### 32.5.21 DMA burst mode

The TIMx timers have the capability to generate multiple DMA requests on a single event. The main purpose is to be able to re-program several timer registers multiple times without software overhead, but it can also be used to read several registers in a row, at regular intervals.

The DMA controller destination is unique and must point to the virtual register TIMx\_DMAR. On a given timer event, the timer launches a sequence of DMA requests (burst). Each write into the TIMx\_DMAR register is actually redirected to one of the timer registers.

The DBL[4:0] bits in the TIMx\_DCR register set the DMA burst length. The timer recognizes a burst transfer when a read or a write access is done to the TIMx\_DMAR address), i.e. the number of transfers (either in half-words or in bytes).

The DBA[4:0] bits in the TIMx\_DCR registers define the DMA base address for DMA transfers (when read/write access are done through the TIMx\_DMAR address). DBA is defined as an offset starting from the address of the TIMx\_CR1 register.

Example:

00000: TIMx\_CR1,  
00001: TIMx\_CR2,  
00010: TIMx\_SMCR,

For example, the timer DMA burst feature could be used to update the contents of the CCRx registers (x = 2, 3, 4) on an update event, with the DMA transferring half words into the CCRx registers.

This is done in the following steps:

1. Configure the corresponding DMA channel as follows:
  - DMA channel peripheral address is the DMAR register address
  - DMA channel memory address is the address of the buffer in the RAM containing the data to be transferred by DMA into the CCRx registers.
  - Number of data to transfer = 3 (See note below).
  - Circular mode disabled.
2. Configure the DCR register by configuring the DBA and DBL bit fields as follows:  
DBL = 3 transfers, DBA = 0xE.
3. Enable the TIMx update DMA request (set the UDE bit in the DIER register).
4. Enable TIMx
5. Enable the DMA channel

This example is for the case where every CCRx register is to be updated once. If every CCRx register is to be updated twice for example, the number of data to transfer should be 6. Let's take the example of a buffer in the RAM containing data1, data2, data3, data4, data5 and data6. The data is transferred to the CCRx registers as follows: on the first update DMA request, data1 is transferred to CCR2, data2 is transferred to CCR3, data3 is transferred to CCR4 and on the second update DMA request, data4 is transferred to CCR2, data5 is transferred to CCR3 and data6 is transferred to CCR4.

*Note:* A null value can be written to the reserved registers.

### 32.5.22 Timer synchronization (TIM15)

The TIMx timers are linked together internally for timer synchronization or chaining. Refer to [Section 31.3.19: Timer synchronization](#) for details.

*Note:* The clock of the slave peripherals (timer, ADC, ...) receiving the TRGO or the TRGO2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

### 32.5.23 Using timer output as trigger for other timers (TIM16/TIM17)

The timers with one channel only do not feature a master mode. However, the OC1 output signal can be used to trigger some other timers (including timers described in other sections of this document). Check the “TIMx internal trigger connection” table of any TIMx\_SMCR register on the device to identify which timers can be targeted as slave.

The OC1 signal pulse width must be programmed to be at least 2 clock cycles of the destination timer, to make sure the slave timer detects the trigger.

For instance, if the destination's timer CK\_INT clock is 4 times slower than the source timer, the OC1 pulse width must be 8 clock cycles.

### 32.5.24 Debug mode

When the microcontroller enters debug mode (Cortex®-M4 core halted), the TIMx counter either continues to work normally or stops, depending on DBG\_TIMx\_STOP configuration bit in DBG module. For more details, refer to [Section 48.16.2: Debug support for timers, RTC, watchdog, bxCAN and I<sup>2</sup>C](#).

For safety purposes, when the counter is stopped (DBG\_TIMx\_STOP = 1), the outputs are disabled (as if the MOE bit was reset). The outputs can either be forced to an inactive state (OSSI bit = 1), or have their control taken over by the GPIO controller (OSSI bit = 0) to force them to Hi-Z.

## 32.6 TIM15 registers

Refer to [Section 1.2](#) for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

### 32.6.1 TIM15 control register 1 (TIM15\_CR1)

Address offset: 0x00

Reset value: 0x0000

| 15   | 14   | 13   | 12   | 11           | 10   | 9        | 8  | 7    | 6    | 5    | 4    | 3   | 2   | 1    | 0   |
|------|------|------|------|--------------|------|----------|----|------|------|------|------|-----|-----|------|-----|
| Res. | Res. | Res. | Res. | UIFRE<br>MAP | Res. | CKD[1:0] |    | ARPE | Res. | Res. | Res. | OPM | URS | UDIS | CEN |
|      |      |      |      | rw           |      | rw       | rw | rw   |      |      |      | rw  | rw  | rw   | rw  |

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 **UIFREMAP**: UIF status bit remapping

0: No remapping. UIF status bit is not copied to TIMx\_CNT register bit 31.

1: Remapping enabled. UIF status bit is copied to TIMx\_CNT register bit 31.

Bit 10 Reserved, must be kept at reset value.

Bits 9:8 **CKD[1:0]**: Clock division

This bitfield indicates the division ratio between the timer clock (CK\_INT) frequency and the dead-time and sampling clock ( $t_{DTS}$ ) used by the dead-time generators and the digital filters (Tlx)

00:  $t_{DTS} = t_{CK\_INT}$

01:  $t_{DTS} = 2 * t_{CK\_INT}$

10:  $t_{DTS} = 4 * t_{CK\_INT}$

11: Reserved, do not program this value

Bit 7 **ARPE**: Auto-reload preload enable

0: TIMx\_ARR register is not buffered

1: TIMx\_ARR register is buffered

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 **OPM**: One-pulse mode

0: Counter is not stopped at update event

1: Counter stops counting at the next update event (clearing the bit CEN)

Bit 2 **URS**: Update request source

This bit is set and cleared by software to select the UEV event sources.

0: Any of the following events generate an update interrupt if enabled. These events can be:

- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller

1: Only counter overflow/underflow generates an update interrupt if enabled

Bit 1 **UDIS**: Update disable

This bit is set and cleared by software to enable/disable UEV event generation.

0: UEV enabled. The Update (UEV) event is generated by one of the following events:

- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller

Buffered registers are then loaded with their preload values.

1: UEV disabled. The Update event is not generated, shadow registers keep their value (ARR, PSC, CCRx). However the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.

Bit 0 **CEN**: Counter enable

0: Counter disabled

1: Counter enabled

*Note: External clock and gated mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.*

### 32.6.2 TIM15 control register 2 (TIM15\_CR2)

Address offset: 0x04

Reset value: 0x0000

| 15   | 14   | 13   | 12   | 11   | 10   | 9     | 8    | 7    | 6        | 5  | 4  | 3    | 2    | 1    | 0    |
|------|------|------|------|------|------|-------|------|------|----------|----|----|------|------|------|------|
| Res. | Res. | Res. | Res. | Res. | OIS2 | OIS1N | OIS1 | TI1S | MMS[2:0] |    |    | CCDS | CCUS | Res. | CCPC |
|      |      |      |      |      | rw   | rw    | rw   | rw   | rw       | rw | rw | rw   | rw   |      | rw   |

Bits 15:11 Reserved, must be kept at reset value.

Bit 10 **OIS2**: Output idle state 2 (OC2 output)

0: OC2=0 when MOE=0

1: OC2=1 when MOE=0

*Note: This bit cannot be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in the TIM15\_BDTR register).*

Bit 9 **OIS1N**: Output Idle state 1 (OC1N output)

0: OC1N=0 after a dead-time when MOE=0

1: OC1N=1 after a dead-time when MOE=0

*Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIM15\_BDTR register).*

Bit 8 **OIS1**: Output Idle state 1 (OC1 output)

0: OC1=0 (after a dead-time if OC1N is implemented) when MOE=0

1: OC1=1 (after a dead-time if OC1N is implemented) when MOE=0

*Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIM15\_BDTR register).*

Bit 7 **TI1S**: TI1 selection

- 0: The TIMx\_CH1 pin is connected to TI1 input
- 1: The TIMx\_CH1, CH2 pins are connected to the TI1 input (XOR combination)

Bits 6:4 **MMS[2:0]**: Master mode selection

These bits allow to select the information to be sent in master mode to slave timers for synchronization (TRGO). The combination is as follows:

- 000: **Reset** - the UG bit from the TIMx\_EGR register is used as trigger output (TRGO). If the reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on TRGO is delayed compared to the actual reset.
- 001: **Enable** - the Counter Enable signal CNT\_EN is used as trigger output (TRGO). It is useful to start several timers at the same time or to control a window in which a slave timer is enable. The Counter Enable signal is generated by a logic AND between CEN control bit and the trigger input when configured in gated mode. When the Counter Enable signal is controlled by the trigger input, there is a delay on TRGO, except if the master/slave mode is selected (see the MSM bit description in TIMx\_SMCR register).
- 010: **Update** - The update event is selected as trigger output (TRGO). For instance a master timer can then be used as a prescaler for a slave timer.
- 011: **Compare Pulse** - The trigger output send a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or a compare match occurred. (TRGO).
- 100: **Compare** - OC1REFC signal is used as trigger output (TRGO).
- 101: **Compare** - OC2REFC signal is used as trigger output (TRGO).

Bit 3 **CCDS**: Capture/compare DMA selection

- 0: CCx DMA request sent when CCx event occurs
- 1: CCx DMA requests sent when update event occurs

Bit 2 **CCUS**: Capture/compare control update selection

- 0: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit only.
- 1: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit or when an rising edge occurs on TRGI.

*Note: This bit acts only on channels that have a complementary output.*

Bit 1 Reserved, must be kept at reset value.

Bit 0 **CCPC**: Capture/compare preloaded control

- 0: CCxE, CCxNE and OCxM bits are not preloaded
- 1: CCxE, CCxNE and OCxM bits are preloaded, after having been written, they are updated only when a commutation event (COM) occurs (COMG bit set or rising edge detected on TRGI, depending on the CCUS bit).

*Note: This bit acts only on channels that have a complementary output.*

### 32.6.3 TIM15 slave mode control register (TIM15\_SMCR)

Address offset: 0x08

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |         |      |      |      |      |          |        |
|------|------|------|------|------|------|------|------|------|---------|------|------|------|------|----------|--------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22      | 21   | 20   | 19   | 18   | 17       | 16     |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.    | Res. | Res. | Res. | Res. | Res.     | SMS[3] |
|      |      |      |      |      |      |      |      |      |         |      |      |      |      |          | rw     |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6       | 5    | 4    | 3    | 2    | 1        | 0      |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | MSM  | TS[2:0] |      |      |      | Res. | SMS[2:0] |        |
|      |      |      |      |      |      |      |      | rw   | rw      | rw   | rw   |      | rw   | rw       | rw     |

Bits 31:17 Reserved, must be kept at reset value.

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **MSM**: Master/slave mode

0: No action

1: The effect of an event on the trigger input (TRGI) is delayed to allow a perfect synchronization between the current timer and its slaves (through TRGO). It is useful if we want to synchronize several timers on a single external event.

Bits 6:4 **TS[2:0]**: Trigger selection

This bit field selects the trigger input to be used to synchronize the counter.

000: Internal Trigger 0 (ITR0)

001: Internal Trigger 1 (ITR1)

010: Internal Trigger 2 (ITR2)

011: Internal Trigger 3 (ITR3)

100: TI1 Edge Detector (TI1F\_ED)

101: Filtered Timer Input 1 (TI1FP1)

110: Filtered Timer Input 2 (TI2FP2)

See [Table 206: TIMx Internal trigger connection on page 1116](#) for more details on ITRx meaning for each Timer.

*Note: These bits must be changed only when they are not used (e.g. when SMS=000) to avoid wrong edge detections at the transition.*

Bit 3 Reserved, must be kept at reset value.

Bits 16, 2, 1, 0 **SMS[3:0]**: Slave mode selection

When external signals are selected the active edge of the trigger signal (TRGI) is linked to the polarity selected on the external input (refer to ETP bit in TIMx\_SMCR for tim\_etr\_in and CCxP/CCxNP bits in TIMx\_CCER register for tim\_ti1fp1 and tim\_ti2fp2).

0000: Slave mode disabled - if CEN = '1' then the prescaler is clocked directly by the internal clock.

0001: Reserved

0010: Reserved

0011: Reserved

0100: Reset Mode - Rising edge of the selected trigger input (TRGI) reinitializes the counter and generates an update of the registers.

0101: Gated Mode - The counter clock is enabled when the trigger input (TRGI) is high. The counter stops (but is not reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

0110: Trigger Mode - The counter starts at a rising edge of the trigger TRGI (but it is not reset). Only the start of the counter is controlled.

0111: External Clock Mode 1 - Rising edges of the selected trigger (TRGI) clock the counter.

1000: Combined reset + trigger mode - Rising edge of the selected trigger input (TRGI) reinitializes the counter, generates an update of the registers and starts the counter.

Other codes: reserved.

*Note: The gated mode must not be used if TI1F\_ED is selected as the trigger input (TS='100'). Indeed, TI1F\_ED outputs 1 pulse for each transition on TI1F, whereas the gated mode checks the level of the trigger signal.*

*Note: The clock of the slave peripherals (timer, ADC, ...) receiving the TRGO or the TRGO2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.*

**Table 206. TIMx Internal trigger connection**

| Slave TIM | ITR0 (TS = 000) | ITR1 (TS = 001) | ITR2 (TS = 010) | ITR3 (TS = 011) |
|-----------|-----------------|-----------------|-----------------|-----------------|
| TIM15     | TIM1            | TIM3            | TIM16 OC1       | TIM17 OC1       |

### 32.6.4 TIM15 DMA/interrupt enable register (TIM15\_DIER)

Address offset: 0x0C

Reset value: 0x0000

| 15   | 14  | 13    | 12   | 11   | 10   | 9     | 8   | 7   | 6   | 5     | 4    | 3    | 2     | 1     | 0   |
|------|-----|-------|------|------|------|-------|-----|-----|-----|-------|------|------|-------|-------|-----|
| Res. | TDE | COMDE | Res. | Res. | Res. | CC1DE | UDE | BIE | TIE | COMIE | Res. | Res. | CC2IE | CC1IE | UIE |

Bit 15 Reserved, must be kept at reset value.

Bit 14 **TDE**: Trigger DMA request enable

0: Trigger DMA request disabled

1: Trigger DMA request enabled

Bit 13 **COMDE**: COM DMA request enable

0: COM DMA request disabled

1: COM DMA request enabled

Bits 12:10 Reserved, must be kept at reset value.

Bit 9 **CC1DE**: Capture/Compare 1 DMA request enable  
 0: CC1 DMA request disabled  
 1: CC1 DMA request enabled

Bit 8 **UDE**: Update DMA request enable  
 0: Update DMA request disabled  
 1: Update DMA request enabled

Bit 7 **BIE**: Break interrupt enable  
 0: Break interrupt disabled  
 1: Break interrupt enabled

Bit 6 **TIE**: Trigger interrupt enable  
 0: Trigger interrupt disabled  
 1: Trigger interrupt enabled

Bit 5 **COMIE**: COM interrupt enable  
 0: COM interrupt disabled  
 1: COM interrupt enabled

Bits 4:3 Reserved, must be kept at reset value.

Bit 2 **CC2IE**: Capture/Compare 2 interrupt enable  
 0: CC2 interrupt disabled  
 1: CC2 interrupt enabled

Bit 1 **CC1IE**: Capture/Compare 1 interrupt enable  
 0: CC1 interrupt disabled  
 1: CC1 interrupt enabled

Bit 0 **UIE**: Update interrupt enable  
 0: Update interrupt disabled  
 1: Update interrupt enabled

### 32.6.5 TIM15 status register (TIM15\_SR)

Address offset: 0x10

Reset value: 0x0000

| 15   | 14   | 13   | 12   | 11   | 10    | 9     | 8    | 7     | 6     | 5     | 4    | 3    | 2     | 1     | 0     |
|------|------|------|------|------|-------|-------|------|-------|-------|-------|------|------|-------|-------|-------|
| Res. | Res. | Res. | Res. | Res. | CC2OF | CC1OF | Res. | BIF   | TIF   | COMIF | Res. | Res. | CC2IF | CC1IF | UIF   |
|      |      |      |      |      | rc_w0 | rc_w0 |      | rc_w0 | rc_w0 | rc_w0 |      |      | rc_w0 | rc_w0 | rc_w0 |

Bits 15:11 Reserved, must be kept at reset value.

Bit 10 **CC2OF**: Capture/Compare 2 overcapture flag  
 Refer to CC1OF description

Bit 9 **CC1OF**: Capture/Compare 1 overcapture flag  
 This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to '0'.  
 0: No overcapture has been detected  
 1: The counter value has been captured in TIMx\_CCR1 register while CC1IF flag was already set

Bit 8 Reserved, must be kept at reset value.

Bit 7 **BIF**: Break interrupt flag

This flag is set by hardware as soon as the break input goes active. It can be cleared by software if the break input is not active.

0: No break event occurred

1: An active level has been detected on the break input

Bit 6 **TIF**: Trigger interrupt flag

This flag is set by hardware on the TRG trigger event (active edge detected on TRGI input when the slave mode controller is enabled in all modes but gated mode, both edges in case gated mode is selected). It is set when the counter starts or stops when gated mode is selected. It is cleared by software.

0: No trigger event occurred

1: Trigger interrupt pending

Bit 5 **COMIF**: COM interrupt flag

This flag is set by hardware on a COM event (once the capture/compare control bits –CCxE, CCxNE, OCxM– have been updated). It is cleared by software.

0: No COM event occurred

1: COM interrupt pending

Bits 4:3 Reserved, must be kept at reset value.

Bit 2 **CC2IF**: Capture/Compare 2 interrupt flag

refer to CC1IF description

Bit 1 **CC1IF**: Capture/Compare 1 interrupt flag

This flag is set by hardware. It is cleared by software (input capture or output compare mode) or by reading the TIMx\_CCR1 register (input capture mode only).

0: No compare match / No input capture occurred

1: A compare match or an input capture occurred

**If channel CC1 is configured as output:** this flag is set when the content of the counter TIMx\_CNT matches the content of the TIMx\_CCR1 register. When the content of TIMx\_CCR1 is greater than the content of TIMx\_ARR, the CC1IF bit goes high on the counter overflow (in up-counting and up/down-counting modes) or underflow (in down-counting mode). There are 3 possible options for flag setting in center-aligned mode, refer to the CMS bits in the TIMx\_CR1 register for the full description.

**If channel CC1 is configured as input:** this bit is set when counter value has been captured in TIMx\_CCR1 register (an edge has been detected on IC1, as per the edge sensitivity defined with the CC1P and CC1NP bits setting, in TIMx\_CCER).

Bit 0 **UIF**: Update interrupt flag

This bit is set by hardware on an update event. It is cleared by software.

0: No update occurred.

1: Update interrupt pending. This bit is set by hardware when the registers are updated:

- At overflow regarding the repetition counter value (update if repetition counter = 0) and if the UDIS=0 in the TIMx\_CR1 register.
- When CNT is reinitialized by software using the UG bit in TIMx\_EGR register, if URS=0 and UDIS=0 in the TIMx\_CR1 register.
- When CNT is reinitialized by a trigger event (refer to [Section 32.6.3: TIM15 slave mode control register \(TIM15\\_SMCR\)](#)), if URS=0 and UDIS=0 in the TIMx\_CR1 register.

### 32.6.6 TIM15 event generation register (TIM15\_EGR)

Address offset: 0x14

Reset value: 0x0000

| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7  | 6  | 5    | 4    | 3    | 2    | 1    | 0  |
|------|------|------|------|------|------|------|------|----|----|------|------|------|------|------|----|
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | BG | TG | COMG | Res. | Res. | CC2G | CC1G | UG |
|      |      |      |      |      |      |      |      | w  | w  | rw   |      |      | w    | w    | w  |

Bits 15:8 Reserved, must be kept at reset value.

**Bit 7 BG:** Break generation

This bit is set by software in order to generate an event, it is automatically cleared by hardware.

0: No action

1: A break event is generated. MOE bit is cleared and BIF flag is set. Related interrupt or DMA transfer can occur if enabled.

**Bit 6 TG:** Trigger generation

This bit is set by software in order to generate an event, it is automatically cleared by hardware.

0: No action

1: The TIF flag is set in TIMx\_SR register. Related interrupt or DMA transfer can occur if enabled

**Bit 5 COMG:** Capture/Compare control update generation

This bit can be set by software, it is automatically cleared by hardware.

0: No action

1: When the CCPC bit is set, it is possible to update the CCxE, CCxNE and OCxM bits

*Note: This bit acts only on channels that have a complementary output.*

Bits 4:3 Reserved, must be kept at reset value.

**Bit 2 CC2G:** Capture/Compare 2 generation

Refer to CC1G description

**Bit 1 CC1G:** Capture/Compare 1 generation

This bit is set by software in order to generate an event, it is automatically cleared by hardware.

0: No action

1: A capture/compare event is generated on channel 1:

**If channel CC1 is configured as output:**

CC1IF flag is set, Corresponding interrupt or DMA request is sent if enabled.

**If channel CC1 is configured as input:**

The current value of the counter is captured in TIMx\_CCR1 register. The CC1IF flag is set, the corresponding interrupt or DMA request is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.

**Bit 0 UG:** Update generation

This bit can be set by software, it is automatically cleared by hardware.

0: No action

1: Reinitialize the counter and generates an update of the registers. Note that the prescaler counter is cleared too (anyway the prescaler ratio is not affected).

### 32.6.7 TIM15 capture/compare mode register 1 (TIM15\_CCMR1)

Address offset: 0x18

Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode.

#### Input capture mode:

|           |      |      |      |             |      |           |      |           |      |      |      |             |      |           |      |
|-----------|------|------|------|-------------|------|-----------|------|-----------|------|------|------|-------------|------|-----------|------|
| 31        | 30   | 29   | 28   | 27          | 26   | 25        | 24   | 23        | 22   | 21   | 20   | 19          | 18   | 17        | 16   |
| Res.      | Res. | Res. | Res. | Res.        | Res. | Res.      | Res. | Res.      | Res. | Res. | Res. | Res.        | Res. | Res.      | Res. |
|           |      |      |      |             |      |           |      |           |      |      |      |             |      |           |      |
| 15        | 14   | 13   | 12   | 11          | 10   | 9         | 8    | 7         | 6    | 5    | 4    | 3           | 2    | 1         | 0    |
| IC2F[3:0] |      |      |      | IC2PSC[1:0] |      | CC2S[1:0] |      | IC1F[3:0] |      |      |      | IC1PSC[1:0] |      | CC1S[1:0] |      |
| r/w       | r/w  | r/w  | r/w  | r/w         | r/w  | r/w       | r/w  | r/w       | r/w  | r/w  | r/w  | r/w         | r/w  | r/w       | r/w  |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:12 **IC2F[3:0]**: Input capture 2 filter

Bits 11:10 **IC2PSC[1:0]**: Input capture 2 prescaler

Bits 9:8 **CC2S[1:0]**: Capture/Compare 2 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC2 channel is configured as output

01: CC2 channel is configured as input, IC2 is mapped on TI2

10: CC2 channel is configured as input, IC2 is mapped on TI1

11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note:* CC2S bits are writable only when the channel is OFF (CC2E = '0' in TIMx\_CCER).

**Bits 7:4 IC1F[3:0]: Input capture 1 filter**

This bit-field defines the frequency used to sample TI1 input and the length of the digital filter applied to TI1. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000: No filter, sampling is done at  $f_{DTS}$

0001:  $f_{SAMPLING}=f_{CK\_INT}$ , N=2

0010:  $f_{SAMPLING}=f_{CK\_INT}$ , N=4

0011:  $f_{SAMPLING}=f_{CK\_INT}$ , N=8

0100:  $f_{SAMPLING}=f_{DTS}/2$ , N=6

0101:  $f_{SAMPLING}=f_{DTS}/2$ , N=8

0110:  $f_{SAMPLING}=f_{DTS}/4$ , N=6

0111:  $f_{SAMPLING}=f_{DTS}/4$ , N=8

1000:  $f_{SAMPLING}=f_{DTS}/8$ , N=6

1001:  $f_{SAMPLING}=f_{DTS}/8$ , N=8

1010:  $f_{SAMPLING}=f_{DTS}/16$ , N=5

1011:  $f_{SAMPLING}=f_{DTS}/16$ , N=6

1100:  $f_{SAMPLING}=f_{DTS}/16$ , N=8

1101:  $f_{SAMPLING}=f_{DTS}/32$ , N=5

1110:  $f_{SAMPLING}=f_{DTS}/32$ , N=6

1111:  $f_{SAMPLING}=f_{DTS}/32$ , N=8

**Bits 3:2 IC1PSC[1:0]: Input capture 1 prescaler**

This bit-field defines the ratio of the prescaler acting on CC1 input (IC1). The prescaler is reset as soon as CC1E='0' (TIMx\_CCER register).

00: no prescaler, capture is done each time an edge is detected on the capture input

01: capture is done once every 2 events

10: capture is done once every 4 events

11: capture is done once every 8 events

**Bits 1:0 CC1S[1:0]: Capture/Compare 1 Selection**

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC1 channel is configured as output

01: CC1 channel is configured as input, IC1 is mapped on TI1

10: CC1 channel is configured as input, IC1 is mapped on TI2

11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note:* CC1S bits are writable only when the channel is OFF (CC1E = '0' in TIMx\_CCER).

### 32.6.8 TIM15 capture/compare mode register 1 [alternate] (TIM15\_CCMR1)

Address offset: 0x18

Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode.

#### Output compare mode:

|      |           |      |      |           |           |           |             |      |           |      |      |           |           |           |             |
|------|-----------|------|------|-----------|-----------|-----------|-------------|------|-----------|------|------|-----------|-----------|-----------|-------------|

| Res. | OC2M[2:0] |      |      | OC2<br>PE | OC2<br>FE | CC2S[1:0] |             | Res. | OC1M[2:0] |      |      | OC1<br>PE | OC1<br>FE | CC1S[1:0] |             |
|      | rw        | rw   | rw   | rw        | rw        | rw        | rw          |      | rw        | rw   | rw   | rw        | rw        | rw        | rw          |

Bits 31:25 Reserved, must be kept at reset value.

Bits 23:17 Reserved, must be kept at reset value.

Bit 15 Reserved, must be kept at reset value.

Bits 24, 14:12 **OC2M[3:0]**: Output Compare 2 mode

Bit 11 **OC2PE**: Output Compare 2 preload enable

Bit 10 **OC2FE**: Output Compare 2 fast enable

Bits 9:8 **CC2S[1:0]**: Capture/Compare 2 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC2 channel is configured as output.

01: CC2 channel is configured as input, IC2 is mapped on TI2.

10: CC2 channel is configured as input, IC2 is mapped on TI1.

11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode is working only if an internal trigger input is selected through the TS bit (TIMx\_SMCR register)

*Note: CC2S bits are writable only when the channel is OFF (CC2E = '0' in TIMx\_CCER).*

Bit 7 Reserved, must be kept at reset value.

Bits 16, 6:4 **OC1M[3:0]**: Output Compare 1 mode

These bits define the behavior of the output reference signal OC1REF from which OC1 and OC1N are derived. OC1REF is active high whereas OC1 and OC1N active level depends on CC1P and CC1NP bits.

0000: Frozen - The comparison between the output compare register TIMx\_CCR1 and the counter TIMx\_CNT has no effect on the outputs.

0001: Set channel 1 to active level on match. OC1REF signal is forced high when the counter TIMx\_CNT matches the capture/compare register 1 (TIMx\_CCR1).

0010: Set channel 1 to inactive level on match. OC1REF signal is forced low when the counter TIMx\_CNT matches the capture/compare register 1 (TIMx\_CCR1).

0011: Toggle - OC1REF toggles when TIMx\_CNT=TIMx\_CCR1.

0100: Force inactive level - OC1REF is forced low.

0101: Force active level - OC1REF is forced high.

0110: PWM mode 1 - Channel 1 is active as long as TIMx\_CNT<TIMx\_CCR1 else inactive.

0111: PWM mode 2 - Channel 1 is inactive as long as TIMx\_CNT<TIMx\_CCR1 else active.

1000: Retriggerable OPM mode 1 - In up-counting mode, the channel is active until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update. In down-counting mode, the channel is inactive until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update.

1001: Retriggerable OPM mode 2 - In up-counting mode, the channel is inactive until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes inactive again at the next update. In down-counting mode, the channel is active until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update.

1010: Reserved

1011: Reserved

1100: Combined PWM mode 1 - OC1REF has the same behavior as in PWM mode 1. OC1REFC is the logical OR between OC1REF and OC2REF.

1101: Combined PWM mode 2 - OC1REF has the same behavior as in PWM mode 2. OC1REFC is the logical AND between OC1REF and OC2REF.

1110: Reserved,

1111: Reserved,

*Note: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx\_BDTR register) and CC1S='00' (the channel is configured in output).*

*In PWM mode, the OCREF level changes only when the result of the comparison changes or when the output compare mode switches from "frozen" mode to "PWM" mode.*

*On channels that have a complementary output, this bit field is preloaded. If the CCPC bit is set in the TIMx\_CR2 register then the OC1M active bits take the new value from the preloaded bits only when a COM event is generated.*

*The OC1M[3] bit is not contiguous, located in bit 16.*

Bit 3 **OC1PE**: Output Compare 1 preload enable

- 0: Preload register on TIMx\_CCR1 disabled. TIMx\_CCR1 can be written at anytime, the new value is taken in account immediately.
- 1: Preload register on TIMx\_CCR1 enabled. Read/Write operations access the preload register. TIMx\_CCR1 preload value is loaded in the active register at each update event.

*Note: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx\_BDTR register) and CC1S='00' (the channel is configured in output).*

Bit 2 **OC1FE**: Output Compare 1 fast enable

This bit decreases the latency between a trigger event and a transition on the timer output. It must be used in one-pulse mode (OPM bit set in TIMx\_CR1 register), to have the output pulse starting as soon as possible after the starting trigger.

- 0: CC1 behaves normally depending on counter and CCR1 values even when the trigger is ON. The minimum delay to activate CC1 output when an edge occurs on the trigger input is 5 clock cycles.
- 1: An active edge on the trigger input acts like a compare match on CC1 output. Then, OC is set to the compare level independently of the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OCFE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 **CC1S[1:0]**: Capture/Compare 1 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

- 00: CC1 channel is configured as output.
- 01: CC1 channel is configured as input, IC1 is mapped on TI1.
- 10: CC1 channel is configured as input, IC1 is mapped on TI2.
- 11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note: CC1S bits are writable only when the channel is OFF (CC1E = '0' in TIMx\_CCER).*

### 32.6.9 TIM15 capture/compare enable register (TIM15\_CCER)

Address offset: 0x20

Reset value: 0x0000

| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7     | 6    | 5    | 4    | 3     | 2     | 1    | 0    |
|------|------|------|------|------|------|------|------|-------|------|------|------|-------|-------|------|------|
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | CC2NP | Res. | CC2P | CC2E | CC1NP | CC1NE | CC1P | CC1E |
|      |      |      |      |      |      |      |      | rw    |      | rw   | rw   | rw    | rw    | rw   | rw   |

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **CC2NP**: Capture/Compare 2 complementary output polarity

Refer to CC1NP description

Bit 6 Reserved, must be kept at reset value.

Bit 5 **CC2P**: Capture/Compare 2 output polarity

Refer to CC1P description

Bit 4 **CC2E**: Capture/Compare 2 output enable

Refer to CC1E description

Bit 3 **CC1NP**: Capture/Compare 1 complementary output polarity

CC1 channel configured as output:

0: OC1N active high

1: OC1N active low

CC1 channel configured as input:

This bit is used in conjunction with CC1P to define the polarity of TI1FP1 and TI2FP1. Refer to CC1P description.

*Note: This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx\_BDTR register) and CC1S="00" (the channel is configured in output).*

*On channels that have a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx\_CR2 register then the CC1NP active bit takes the new value from the preloaded bit only when a Commutation event is generated.*

Bit 2 **CC1NE**: Capture/Compare 1 complementary output enable

0: Off - OC1N is not active. OC1N level is then function of MOE, OSS1, OSSR, OIS1, OIS1N and CC1E bits.

1: On - OC1N signal is output on the corresponding output pin depending on MOE, OSS1, OSSR, OIS1, OIS1N and CC1E bits.

Bit 1 **CC1P**: Capture/Compare 1 output polarity

0: OC1 active high (output mode) / Edge sensitivity selection (input mode, see below)

1: OC1 active low (output mode) / Edge sensitivity selection (input mode, see below)

**When CC1 channel is configured as input**, both CC1NP/CC1P bits select the active polarity of TI1FP1 and TI2FP1 for trigger or capture operations.

CC1NP=0, CC1P=0: non-inverted/rising edge. The circuit is sensitive to TIxFP1 rising edge (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger operation in gated mode or encoder mode).

CC1NP=0, CC1P=1: inverted/falling edge. The circuit is sensitive to TIxFP1 falling edge (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is inverted (trigger operation in gated mode or encoder mode).

CC1NP=1, CC1P=1: non-inverted/both edges/ The circuit is sensitive to both TIxFP1 rising and falling edges (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger operation in gated mode). This configuration must not be used in encoder mode.

CC1NP=1, CC1P=0: this configuration is reserved, it must not be used.

*Note: This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx\_BDTR register).*

*On channels that have a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx\_CR2 register then the CC1P active bit takes the new value from the preloaded bit only when a Commutation event is generated.*

Bit 0 **CC1E**: Capture/Compare 1 output enable

0: Capture mode disabled / OC1 is not active (see below)

1: Capture mode enabled / OC1 signal is output on the corresponding output pin

**When CC1 channel is configured as output**, the OC1 level depends on MOE, OSS1, OSSR, OIS1, OIS1N and CC1NE bits, regardless of the CC1E bits state. Refer to [Table 207](#) for details.

**Table 207. Output control bits for complementary OCx and OCxN channels with break feature (TIM15)**

| Control bits |          |          |          |           | Output states <sup>(1)</sup>                                                                                                                                                                                                                           |                                                                         |

|              |          |          | 1        | 1         |                                                                                                                                                                                                                                                        |                                                                         |

1. When both outputs of a channel are not used (control taken over by GPIO controller), the OISx, OISxN, CCxP and CCxNP bits must be kept cleared.

**Note:** The state of the external I/O pins connected to the complementary OCx and OCxN channels depends on the OCx and OCxN channel state and GPIO control and alternate function registers.

**32.6.10 TIM15 counter (TIM15\_CNT)**

Address offset: 0x24

Reset value: 0x0000 0000

|            |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |

Bit 31 **UIFCPY**: UIF Copy

This bit is a read-only copy of the UIF bit in the TIMx\_ISR register.

Bits 30:16 Reserved, must be kept at reset value.

Bits 15:0 **CNT[15:0]**: Counter value**32.6.11 TIM15 prescaler (TIM15\_PSC)**

Address offset: 0x28

Reset value: 0x0000

|           |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|-----------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| 15        | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
| PSC[15:0] |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |

Bits 15:0 **PSC[15:0]**: Prescaler valueThe counter clock frequency (CK\_CNT) is equal to  $f_{CK\_PSC} / (PSC[15:0] + 1)$ .

PSC contains the value to be loaded in the active prescaler register at each update event (including when the counter is cleared through UG bit of TIMx\_EGR register or through trigger controller when configured in "reset mode").

**32.6.12 TIM15 auto-reload register (TIM15\_ARR)**

Address offset: 0x2C

Reset value: 0xFFFF

|           |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|-----------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| 15        | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
| ARR[15:0] |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
| r/w       | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w |

Bits 15:0 **ARR[15:0]**: Auto-reload value

ARR is the value to be loaded in the actual auto-reload register.

Refer to the [Section 32.5.1: Time-base unit on page 1078](#) for more details about ARR update and behavior.

The counter is blocked while the auto-reload value is null.

**32.6.13 TIM15 repetition counter register (TIM15\_RCR)**

Address offset: 0x30

Reset value: 0x0000

| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7        | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|------|------|------|------|------|------|------|------|----------|----|----|----|----|----|----|----|
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | REP[7:0] |    |    |    |    |    |    |    |
|      |      |      |      |      |      |      |      | rw       | rw | rw | rw | rw | rw | rw | rw |

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **REP[7:0]**: Repetition counter value

These bits allow the user to set-up the update rate of the compare registers (i.e. periodic transfers from preload to active registers) when preload registers are enable, as well as the update interrupt generation rate, if this interrupt is enable.

Each time the REP\_CNT related downcounter reaches zero, an update event is generated and it restarts counting from REP value. As REP\_CNT is reloaded with REP value only at the repetition update event U\_RC, any write to the TIMx\_RCR register is not taken in account until the next repetition update event.

It means in PWM mode (REP+1) corresponds to the number of PWM periods in edge-aligned mode.

**32.6.14 TIM15 capture/compare register 1 (TIM15\_CCR1)**

Address offset: 0x34

Reset value: 0x0000

| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| CCR1[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw         | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 15:0 **CCR1[15:0]**: Capture/Compare 1 value**If channel CC1 is configured as output:**

CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIMx\_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx\_CNT and signaled on OC1 output.

**If channel CC1 is configured as input:**

CCR1 is the counter value transferred by the last input capture 1 event (IC1).

### 32.6.15 TIM15 capture/compare register 2 (TIM15\_CCR2)

Address offset: 0x38

Reset value: 0x0000

|            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| CCR2[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw         | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 15:0 **CCR2[15:0]**: Capture/Compare 2 value

**If channel CC2 is configured as output:**

CCR2 is the value to be loaded in the actual capture/compare 2 register (preload value). It is loaded permanently if the preload feature is not selected in the TIMx\_CCMR2 register (bit OC2PE). Else the preload value is copied in the active capture/compare 2 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx\_CNT and signalled on OC2 output.

**If channel CC2 is configured as input:**

CCR2 is the counter value transferred by the last input capture 2 event (IC2).

### 32.6.16 TIM15 break and dead-time register (TIM15\_BDTR)

Address offset: 0x44

Reset value: 0x0000 0000

|      |      |      |      |      |      |           |      |          |      |      |      |      |      |      |      |
|------|------|------|------|------|------|-----------|------|----------|------|------|------|------|------|------|------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25        | 24   | 23       | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Res. | Res. | Res. | Res. | Res. | Res. | Res.      | Res. | Res.     | Res. | Res. | Res. | Res. | Res. | Res. | Res. |
|      |      |      |      |      |      |           |      |          |      |      |      |      |      |      |      |
| 15   | 14   | 13   | 12   | 11   | 10   | 9         | 8    | 7        | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| MOE  | AOE  | BKP  | BKE  | OSSR | OSSI | LOCK[1:0] |      | DTG[7:0] |      |      |      |      |      |      |      |
| rw   | rw   | rw   | rw   | rw   | rw   | rw        | rw   | rw       | rw   | rw   | rw   | rw   | rw   | rw   | rw   |

**Note:** As the AOE, BKP, BKE, OSSI, OSSR and DTG[7:0] bits may be write-locked depending on the LOCK configuration, it may be necessary to configure all of them during the first write access to the TIMx\_BDTR register.

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:16 Reserved, must be kept at reset value.

Bit 15 **MOE**: Main output enable

This bit is cleared asynchronously by hardware as soon as the break input is active. It is set by software or automatically depending on the AOE bit. It is acting only on the channels which are configured in output.

0: OC and OCN outputs are disabled or forced to idle state depending on the OSSI bit.

1: OC and OCN outputs are enabled if their respective enable bits are set (CCxE, CCxNE in TIMx\_CCER register)

See OC/OCN enable description for more details ([Section 32.6.9: TIM15 capture/compare enable register \(TIM15\\_CCER\) on page 1124](#)).

Bit 14 **AOE**: Automatic output enable

0: MOE can be set only by software

1: MOE can be set by software or automatically at the next update event (if the break input is not be active)

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

Bit 13 **BKP**: Break polarity

0: Break input BRK is active low

1: Break input BRK is active high

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

*Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.*

Bit 12 **BKE**: Break enable

0: Break inputs (BRK and CCS clock failure event) disabled

1: Break inputs (BRK and CCS clock failure event) enabled

This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).

*Note: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.*

Bit 11 **OSSR**: Off-state selection for Run mode

This bit is used when MOE=1 on channels that have a complementary output which are configured as outputs. OSSR is not implemented if no complementary output is implemented in the timer.

See OC/OCN enable description for more details ([Section 32.6.9: TIM15 capture/compare enable register \(TIM15\\_CCER\) on page 1124](#)).

0: When inactive, OC/OCN outputs are disabled (the timer releases the output control which is taken over by the GPIO, which forces a Hi-Z state)

1: When inactive, OC/OCN outputs are enabled with their inactive level as soon as CCxE=1 or CCxNE=1 (the output is still controlled by the timer).

*Note: This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx\_BDTR register).*

Bit 10 **OSSI**: Off-state selection for Idle mode

This bit is used when MOE=0 on channels configured as outputs.

See OC/OCN enable description for more details ([Section 32.6.9: TIM15 capture/compare enable register \(TIM15\\_CCER\) on page 1124](#)).

0: When inactive, OC/OCN outputs are disabled (OC/OCN enable output signal=0)

1: When inactive, OC/OCN outputs are forced first with their idle level as soon as CCxE=1 or CCxNE=1. OC/OCN enable output signal=1)

*Note: This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx\_BDTR register).*

Bits 9:8 **LOCK[1:0]**: Lock configuration

These bits offer a write protection against software errors.

00: LOCK OFF - No bit is write protected

01: LOCK Level 1 = DTG bits in TIMx\_BDTR register, OISx and OISxN bits in TIMx\_CR2 register and BKE/BKP/AOE bits in TIMx\_BDTR register can no longer be written

10: LOCK Level 2 = LOCK Level 1 + CC Polarity bits (CCxP/CCxNP bits in TIMx\_CCER register, as long as the related channel is configured in output through the CCxS bits) as well as OSSR and OSSI bits can no longer be written.

11: LOCK Level 3 = LOCK Level 2 + CC Control bits (OCxM and OCxPE bits in TIMx\_CCMRx registers, as long as the related channel is configured in output through the CCxS bits) can no longer be written.

*Note: The LOCK bits can be written only once after the reset. Once the TIMx\_BDTR register has been written, their content is frozen until the next reset.*

Bits 7:0 **DTG[7:0]**: Dead-time generator setup

This bit-field defines the duration of the dead-time inserted between the complementary outputs. DT correspond to this duration.

$DTG[7:5] = 0xx \Rightarrow DT = DTG[7:0] \times t_{dtg}$  with  $t_{dtg} = t_{DTS}$

$DTG[7:5] = 10x \Rightarrow DT = (64+DTG[5:0]) \times t_{dtg}$  with  $t_{dtg} = 2 \times t_{DTS}$

$DTG[7:5] = 110 \Rightarrow DT = (32+DTG[4:0]) \times t_{dtg}$  with  $t_{dtg} = 8 \times t_{DTS}$

$DTG[7:5] = 111 \Rightarrow DT = (32+DTG[4:0]) \times t_{dtg}$  with  $t_{dtg} = 16 \times t_{DTS}$

Example if  $t_{DTS} = 125$  ns (8 MHz), dead-time possible values are:

0 to 15875 ns by 125 ns steps,

16  $\mu$ s to 31750 ns by 250 ns steps,

32  $\mu$ s to 63  $\mu$ s by 1  $\mu$ s steps,

64  $\mu$ s to 126  $\mu$ s by 2  $\mu$ s steps

*Note: This bit-field can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx\_BDTR register).*

**32.6.17 TIM15 DMA control register (TIM15\_DCR)**

Address offset: 0x48

Reset value: 0x0000

| 15   | 14   | 13   | 12       | 11 | 10 | 9  | 8  | 7    | 6    | 5    | 4        | 3  | 2  | 1  | 0  |
|------|------|------|----------|----|----|----|----|------|------|------|----------|----|----|----|----|
| Res. | Res. | Res. | DBL[4:0] |    |    |    |    | Res. | Res. | Res. | DBA[4:0] |    |    |    |    |
|      |      |      | rw       | rw | rw | rw | rw |      |      |      | rw       | rw | rw | rw | rw |

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:8 **DBL[4:0]**: DMA burst length

This 5-bit field defines the length of DMA transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIMx\_DMAR address).

00000: 1 transfer,

00001: 2 transfers,

00010: 3 transfers,

...

10001: 18 transfers.

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **DBA[4:0]**: DMA base address

This 5-bit field defines the base-address for DMA transfers (when read/write access are done through the TIMx\_DMAR address). DBA is defined as an offset starting from the address of the TIMx\_CR1 register.

Example:

00000: TIMx\_CR1,  
00001: TIMx\_CR2,  
00010: TIMx\_SMCR,  
...

### 32.6.18 TIM15 DMA address for full transfer (TIM15\_DMAR)

Address offset: 0x4C

Reset value: 0x0000

| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| DMAB[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw         | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 15:0 **DMAB[15:0]**: DMA register for burst accesses

A read or write operation to the DMAR register accesses the register located at the address  
(TIMx\_CR1 address) + (DBA + DMA index) x 4

where TIMx\_CR1 address is the address of the control register 1, DBA is the DMA base address configured in TIMx\_DCR register, DMA index is automatically controlled by the DMA transfer, and ranges from 0 to DBL (DBL configured in TIMx\_DCR).

### 32.6.19 TIM15 option register 1 (TIM15\_OR1)

Address offset: 0x50

Reset value: 0x0000

| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | ENCODER_MODE[1:0] |      | T11_RMP |
|      |      |      |      |      |      |      |      |      |      |      |      |      | rw                | rw   | rw      |

Bits 31:3 Reserved, must be kept at reset value.

Bits 2:1 **ENCODER\_MODE[1:0]**: Encoder mode

00: No redirection

01: TIM2 IC1 and TIM2 IC2 are connected to TIM15 IC1 and TIM15 IC2 respectively

10: TIM3 IC1 and TIM3 IC2 are connected to TIM15 IC1 and TIM15 IC2 respectively

11: TIM4 IC1 and TIM4 IC2 are connected to TIM15 IC1 and TIM15 IC2 respectively

Bit 0 **T11\_RMP**: Input capture 1 remap

0: TIM15 input capture 1 is connected to I/O

1: TIM15 input capture 1 is connected to LSE

### 32.6.20 TIM15 option register 2 (TIM15\_OR2)

Address offset: 0x60

Reset value: 0x0000 0001

| 31   | 30   | 29   | 28   | 27          | 26          | 25    | 24            | 23   | 22   | 21   | 20   | 19   | 18          | 17          | 16    |

|      |      |      |      |             |             |       |               |      |      |      |      |      |             |             |       |
| 15   | 14   | 13   | 12   | 11          | 10          | 9     | 8             | 7    | 6    | 5    | 4    | 3    | 2           | 1           | 0     |
| Res. | Res. | Res. | Res. | BKCM<br>P2P | BKCM<br>P1P | BKINP | BKDF1<br>BK0E | Res. | Res. | Res. | Res. | Res. | BKCM<br>P2E | BKCM<br>P1E | BKINE |
|      |      |      |      | rw          | rw          | rw    | rw            |      |      |      |      |      | rw          | rw          | rw    |

Bits 31:12 Reserved, must be kept at reset value.

**Bit 11 BKCOMP2P:** BRK COMP2 input polarity

This bit selects the COMP2 input sensitivity. It must be programmed together with the BKP polarity bit.

0: COMP2 input is active low

1: COMP2 input is active high

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

**Bit 10 BKCOMP1P:** BRK COMP1 input polarity

This bit selects the COMP1 input sensitivity. It must be programmed together with the BKP polarity bit.

0: COMP1 input is active low

1: COMP1 input is active high

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

**Bit 9 BKINP:** BRK BKIN input polarity

This bit selects the BKIN alternate function input sensitivity. It must be programmed together with the BKP polarity bit.

0: BKIN input is active low

1: BKIN input is active high

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

**Bit 8 BKDF1BK0E:** BRK dfsdm1\_break[0] enable

This bit enables the dfsdm1\_break[0] for the timer's BRK input. dfsdm1\_break[0] output is 'ORed' with the other BRK sources.

0: dfsdm1\_break[0] input disabled

1: dfsdm1\_break[0] input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

Bits 7:3 Reserved, must be kept at reset value.

**Bit 2 BKCOMP2E:** BRK COMP2 enable

This bit enables the COMP2 for the timer's BRK input. COMP2 output is 'ORed' with the other BRK sources.

0: COMP2 input disabled

1: COMP2 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

Bit 1 **BKCOMP1E**: BRK COMP1 enable

This bit enables the COMP1 for the timer's BRK input. COMP1 output is 'ORed' with the other BRK sources.

0: COMP1 input disabled

1: COMP1 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

Bit 0 **BKINE**: BRK BKIN input enable

This bit enables the BKIN alternate function input for the timer's BRK input. BKIN input is 'ORed' with the other BRK sources.

0: BKIN input disabled

1: BKIN input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

## 32.6.21 TIM15 register map

TIM15 registers are mapped as 16-bit addressable registers as described in the table below:

**Table 208. TIM15 register map and reset values**

| Offset | Register name | 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16     | 15   | 14   | 13    | 12   | 11      | 10   | 9         | 8     | 7    | 6        | 5    | 4     | 3    | 2        | 1     | 0     |     |
|--------|---------------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|--------|------|------|-------|------|---------|------|-----------|-------|------|----------|------|-------|------|----------|-------|-------|-----|

## 32.7 TIM16/TIM17 registers

Refer to [Section 1.2](#) for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

### 32.7.1 TIMx control register 1 (TIMx\_CR1)(x = 16 to 17)

Address offset: 0x00

Reset value: 0x0000

| 15   | 14   | 13   | 12   | 11           | 10   | 9        | 8  | 7    | 6    | 5    | 4    | 3   | 2   | 1    | 0   |
|------|------|------|------|--------------|------|----------|----|------|------|------|------|-----|-----|------|-----|
| Res. | Res. | Res. | Res. | UIFRE<br>MAP | Res. | CKD[1:0] |    | ARPE | Res. | Res. | Res. | OPM | URS | UDIS | CEN |
|      |      |      |      | rw           |      | rw       | rw | rw   |      |      |      | rw  | rw  | rw   | rw  |

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 **UIFREMAP**: UIF status bit remapping

0: No remapping. UIF status bit is not copied to TIMx\_CNT register bit 31.

1: Remapping enabled. UIF status bit is copied to TIMx\_CNT register bit 31.

Bit 10 Reserved, must be kept at reset value.

Bits 9:8 **CKD[1:0]**: Clock division

This bit-field indicates the division ratio between the timer clock (CK\_INT) frequency and the dead-time and sampling clock ( $t_{DTS}$ ) used by the dead-time generators and the digital filters (Tlx),

00:  $t_{DTS} = t_{CK\_INT}$

01:  $t_{DTS} = 2 * t_{CK\_INT}$

10:  $t_{DTS} = 4 * t_{CK\_INT}$

11: Reserved, do not program this value

Bit 7 **ARPE**: Auto-reload preload enable

0: TIMx\_ARR register is not buffered

1: TIMx\_ARR register is buffered

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 **OPM**: One pulse mode

0: Counter is not stopped at update event

1: Counter stops counting at the next update event (clearing the bit CEN)

Bit 2 **URS**: Update request source

This bit is set and cleared by software to select the UEV event sources.

0: Any of the following events generate an update interrupt or DMA request if enabled.

These events can be:

- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller

1: Only counter overflow/underflow generates an update interrupt or DMA request if enabled.

Bit 1 **UDIS**: Update disable

This bit is set and cleared by software to enable/disable UEV event generation.

0: UEV enabled. The Update (UEV) event is generated by one of the following events:

- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller

Buffered registers are then loaded with their preload values.

1: UEV disabled. The Update event is not generated, shadow registers keep their value (ARR, PSC, CCRx). However the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.

Bit 0 **CEN**: Counter enable

0: Counter disabled

1: Counter enabled

*Note: External clock and gated mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.*

### 32.7.2 TIMx control register 2 (TIMx\_CR2)(x = 16 to 17)

Address offset: 0x04

Reset value: 0x0000

| 15   | 14   | 13   | 12   | 11   | 10   | 9     | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
|------|------|------|------|------|------|-------|------|------|------|------|------|------|------|------|------|
| Res. | Res. | Res. | Res. | Res. | Res. | OIS1N | OIS1 | Res. | Res. | Res. | Res. | CCDS | CCUS | Res. | CCPC |
|      |      |      |      |      |      | rw    | rw   |      |      |      |      | rw   | rw   |      | rw   |

Bits 15:10 Reserved, must be kept at reset value.

Bit 9 **OIS1N**: Output Idle state 1 (OC1N output)

0: OC1N=0 after a dead-time when MOE=0

1: OC1N=1 after a dead-time when MOE=0

*Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx\_BDTR register).*

Bit 8 **OIS1**: Output Idle state 1 (OC1 output)

0: OC1=0 (after a dead-time if OC1N is implemented) when MOE=0

1: OC1=1 (after a dead-time if OC1N is implemented) when MOE=0

*Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx\_BDTR register).*

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **CCDS**: Capture/compare DMA selection

0: CCx DMA request sent when CCx event occurs

1: CCx DMA requests sent when update event occurs

Bit 2 **CCUS**: Capture/compare control update selection

0: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit only.

1: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit or when an rising edge occurs on TRGI.

*Note: This bit acts only on channels that have a complementary output.*

Bit 1 Reserved, must be kept at reset value.

Bit 0 **CCPC**: Capture/compare preloaded control

0: CCxE, CCxNE and OCxM bits are not preloaded

1: CCxE, CCxNE and OCxM bits are preloaded, after having been written, they are updated only when COM bit is set.

*Note: This bit acts only on channels that have a complementary output.*

### 32.7.3 TIMx DMA/interrupt enable register (TIMx\_DIER)(x = 16 to 17)

Address offset: 0x0C

Reset value: 0x0000

| 15   | 14   | 13   | 12   | 11   | 10   | 9     | 8   | 7   | 6    | 5     | 4    | 3    | 2    | 1     | 0   |
|------|------|------|------|------|------|-------|-----|-----|------|-------|------|------|------|-------|-----|
| Res. | Res. | Res. | Res. | Res. | Res. | CC1DE | UDE | BIE | Res. | COMIE | Res. | Res. | Res. | CC1IE | UIE |
|      |      |      |      |      |      | rw    | rw  | rw  |      | rw    |      |      |      | rw    | rw  |

Bits 15:10 Reserved, must be kept at reset value.

Bit 9 **CC1DE**: Capture/Compare 1 DMA request enable

0: CC1 DMA request disabled

1: CC1 DMA request enabled

Bit 8 **UDE**: Update DMA request enable

0: Update DMA request disabled

1: Update DMA request enabled

Bit 7 **BIE**: Break interrupt enable

0: Break interrupt disabled

1: Break interrupt enabled

Bit 6 Reserved, must be kept at reset value.

Bit 5 **COMIE**: COM interrupt enable

0: COM interrupt disabled

1: COM interrupt enabled

Bits 4:2 Reserved, must be kept at reset value.

Bit 1 **CC1IE**: Capture/Compare 1 interrupt enable

0: CC1 interrupt disabled

1: CC1 interrupt enabled

Bit 0 **UIE**: Update interrupt enable

0: Update interrupt disabled

1: Update interrupt enabled

### 32.7.4 TIMx status register (TIMx\_SR)(x = 16 to 17)

Address offset: 0x10

Reset value: 0x0000

| 15   | 14   | 13   | 12   | 11   | 10   | 9     | 8    | 7     | 6    | 5     | 4    | 3    | 2    | 1     | 0     |
|------|------|------|------|------|------|-------|------|-------|------|-------|------|------|------|-------|-------|
| Res. | Res. | Res. | Res. | Res. | Res. | CC1OF | Res. | BIF   | Res. | COMIF | Res. | Res. | Res. | CC1IF | UIF   |
|      |      |      |      |      |      | rc_w0 |      | rc_w0 |      | rc_w0 |      |      |      | rc_w0 | rc_w0 |

Bits 15:10 Reserved, must be kept at reset value.

Bit 9 **CC1OF**: Capture/Compare 1 overcapture flag

This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to '0'.

0: No overcapture has been detected

1: The counter value has been captured in TIMx\_CCR1 register while CC1IF flag was already set

Bit 8 Reserved, must be kept at reset value.

Bit 7 **BIF**: Break interrupt flag

This flag is set by hardware as soon as the break input goes active. It can be cleared by software if the break input is not active.

0: No break event occurred

1: An active level has been detected on the break input

Bit 6 Reserved, must be kept at reset value.

Bit 5 **COMIF**: COM interrupt flag

This flag is set by hardware on a COM event (once the capture/compare control bits –CCxE, CCxNE, OCxM– have been updated). It is cleared by software.

0: No COM event occurred

1: COM interrupt pending

Bits 4:2 Reserved, must be kept at reset value.

Bit 1 **CC1IF**: Capture/Compare 1 interrupt flag

This flag is set by hardware. It is cleared by software (input capture or output compare mode) or by reading the TIMx\_CCR1 register (input capture mode only).

0: No compare match / No input capture occurred

1: A compare match or an input capture occurred

**If channel CC1 is configured as output:** this flag is set when the content of the counter TIMx\_CNT matches the content of the TIMx\_CCR1 register. When the content of TIMx\_CCR1 is greater than the content of TIMx\_ARR, the CC1IF bit goes high on the counter overflow (in up-counting and up/down-counting modes) or underflow (in down-counting mode). There are 3 possible options for flag setting in center-aligned mode, refer to the CMS bits in the TIMx\_CR1 register for the full description.

**If channel CC1 is configured as input:** this bit is set when counter value has been captured in TIMx\_CCR1 register (an edge has been detected on IC1, as per the edge sensitivity defined with the CC1P and CC1NP bits setting, in TIMx\_CCER).

Bit 0 **UIF**: Update interrupt flag

This bit is set by hardware on an update event. It is cleared by software.

0: No update occurred.

1: Update interrupt pending. This bit is set by hardware when the registers are updated:

- At overflow regarding the repetition counter value (update if repetition counter = 0) and if the UDIS=0 in the TIMx\_CR1 register.
- When CNT is reinitialized by software using the UG bit in TIMx\_EGR register, if URS=0 and UDIS=0 in the TIMx\_CR1 register.

### 32.7.5 TIMx event generation register (TIMx\_EGR)(x = 16 to 17)

Address offset: 0x14

Reset value: 0x0000

| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7  | 6    | 5    | 4    | 3    | 2    | 1    | 0  |
|------|------|------|------|------|------|------|------|----|------|------|------|------|------|------|----|
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | BG | Res. | COMG | Res. | Res. | Res. | CC1G | UG |
|      |      |      |      |      |      |      |      | w  |      | w    |      |      |      | w    | w  |

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **BG**: Break generation

This bit is set by software in order to generate an event, it is automatically cleared by hardware.

0: No action.

1: A break event is generated. MOE bit is cleared and BIF flag is set. Related interrupt or DMA transfer can occur if enabled.

Bit 6 Reserved, must be kept at reset value.

Bit 5 **COMG**: Capture/Compare control update generation

This bit can be set by software, it is automatically cleared by hardware.

0: No action

1: When the CCPC bit is set, it is possible to update the CCxE, CCxNE and OCxM bits

*Note: This bit acts only on channels that have a complementary output.*

Bits 4:2 Reserved, must be kept at reset value.

Bit 1 **CC1G**: Capture/Compare 1 generation

This bit is set by software in order to generate an event, it is automatically cleared by hardware.

0: No action.

1: A capture/compare event is generated on channel 1:

**If channel CC1 is configured as output:**

CC1IF flag is set, Corresponding interrupt or DMA request is sent if enabled.

**If channel CC1 is configured as input:**

The current value of the counter is captured in TIMx\_CCR1 register. The CC1IF flag is set, the corresponding interrupt or DMA request is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.

Bit 0 **UG**: Update generation

This bit can be set by software, it is automatically cleared by hardware.

0: No action.

1: Reinitialize the counter and generates an update of the registers. Note that the prescaler counter is cleared too (anyway the prescaler ratio is not affected).

### 32.7.6 TIMx capture/compare mode register 1 (TIMx\_CCMR1)(x = 16 to 17)

Address offset: 0x18

Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode.

#### Input capture mode:

|      |      |      |      |      |      |      |      |           |      |      |      |             |      |           |      |
|------|------|------|------|------|------|------|------|-----------|------|------|------|-------------|------|-----------|------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23        | 22   | 21   | 20   | 19          | 18   | 17        | 16   |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.      | Res. | Res. | Res. | Res.        | Res. | Res.      | Res. |
|      |      |      |      |      |      |      |      |           |      |      |      |             |      |           |      |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7         | 6    | 5    | 4    | 3           | 2    | 1         | 0    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | IC1F[3:0] |      |      |      | IC1PSC[1:0] |      | CC1S[1:0] |      |
|      |      |      |      |      |      |      |      | rw        | rw   | rw   | rw   | rw          | rw   | rw        | rw   |

Bits 31:8 Reserved, must be kept at reset value.

#### Bits 7:4 IC1F[3:0]: Input capture 1 filter

This bit-field defines the frequency used to sample TI1 input and the length of the digital filter applied to TI1. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000: No filter, sampling is done at  $f_{DTS}$

0001:  $f_{SAMPLING}=f_{CK\_INT}$ , N=2

0010:  $f_{SAMPLING}=f_{CK\_INT}$ , N=4

0011:  $f_{SAMPLING}=f_{CK\_INT}$ , N=8

0100:  $f_{SAMPLING}=f_{DTS}/2$ , N=

0101:  $f_{SAMPLING}=f_{DTS}/2$ , N=8

0110:  $f_{SAMPLING}=f_{DTS}/4$ , N=6

0111:  $f_{SAMPLING}=f_{DTS}/4$ , N=8

1000:  $f_{SAMPLING}=f_{DTS}/8$ , N=6

1001:  $f_{SAMPLING}=f_{DTS}/8$ , N=8

1010:  $f_{SAMPLING}=f_{DTS}/16$ , N=5

1011:  $f_{SAMPLING}=f_{DTS}/16$ , N=6

1100:  $f_{SAMPLING}=f_{DTS}/16$ , N=8

1101:  $f_{SAMPLING}=f_{DTS}/32$ , N=5

1110:  $f_{SAMPLING}=f_{DTS}/32$ , N=6

1111:  $f_{SAMPLING}=f_{DTS}/32$ , N=8

#### Bits 3:2 IC1PSC[1:0]: Input capture 1 prescaler

This bit-field defines the ratio of the prescaler acting on CC1 input (IC1).

The prescaler is reset as soon as CC1E='0' (TIMx\_CCER register).

00: no prescaler, capture is done each time an edge is detected on the capture input.

01: capture is done once every 2 events

10: capture is done once every 4 events

11: capture is done once every 8 events

Bits 1:0 **CC1S[1:0]**: Capture/Compare 1 Selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC1 channel is configured as output

01: CC1 channel is configured as input, IC1 is mapped on TI1

Others: Reserved

*Note: CC1S bits are writable only when the channel is OFF (CC1E = '0' in TIMx\_CCER).*

### 32.7.7 TIMx capture/compare mode register 1 [alternate] (TIMx\_CCMR1)(x = 16 to 17)

Address offset: 0x18

Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode.

**Output compare mode:**

|      |      |      |      |      |      |      |      |      |           |      |      |       |       |           |         |
|------|------|------|------|------|------|------|------|------|-----------|------|------|-------|-------|-----------|---------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22        | 21   | 20   | 19    | 18    | 17        | 16      |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.      | Res. | Res. | Res.  | Res.  | Res.      | OC1M[3] |
|      |      |      |      |      |      |      |      |      |           |      |      |       |       |           | r/w     |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6         | 5    | 4    | 3     | 2     | 1         | 0       |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | OC1M[2:0] |      |      | OC1PE | OC1FE | CC1S[1:0] |         |
|      |      |      |      |      |      |      |      |      | r/w       | r/w  | r/w  | r/w   | r/w   | r/w       | r/w     |

Bits 31:17 Reserved, must be kept at reset value.

Bits 15:7 Reserved, must be kept at reset value.

Bits 16, 6:4 **OC1M[3:0]**: Output Compare 1 mode

These bits define the behavior of the output reference signal OC1REF from which OC1 and OC1N are derived. OC1REF is active high whereas OC1 and OC1N active level depends on CC1P and CC1NP bits.

0000: Frozen - The comparison between the output compare register TIMx\_CCR1 and the counter TIMx\_CNT has no effect on the outputs. This mode can be used when the timer serves as a software timebase. When the frozen mode is enabled during timer operation, the output keeps the state (active or inactive) it had before entering the frozen state.

0001: Set channel 1 to active level on match. OC1REF signal is forced high when the counter TIMx\_CNT matches the capture/compare register 1 (TIMx\_CCR1).

0010: Set channel 1 to inactive level on match. OC1REF signal is forced low when the counter TIMx\_CNT matches the capture/compare register 1 (TIMx\_CCR1).

0011: Toggle - OC1REF toggles when TIMx\_CNT=TIMx\_CCR1.

0100: Force inactive level - OC1REF is forced low.

0101: Force active level - OC1REF is forced high.

0110: PWM mode 1 - Channel 1 is active as long as TIMx\_CNT<TIMx\_CCR1 else inactive.

0111: PWM mode 2 - Channel 1 is inactive as long as TIMx\_CNT<TIMx\_CCR1 else active.

All other values: Reserved

*Note: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx\_BDTR register) and CC1S='00' (the channel is configured in output).*

*In PWM mode 1 or 2, the OCREF level changes only when the result of the comparison changes or when the output compare mode switches from "frozen" mode to "PWM" mode.*

*The OC1M[3] bit is not contiguous, located in bit 16.*

Bit 3 **OC1PE**: Output Compare 1 preload enable

0: Preload register on TIMx\_CCR1 disabled. TIMx\_CCR1 can be written at anytime, the new value is taken in account immediately.

1: Preload register on TIMx\_CCR1 enabled. Read/Write operations access the preload register. TIMx\_CCR1 preload value is loaded in the active register at each update event.

*Note: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx\_BDTR register) and CC1S='00' (the channel is configured in output).*

Bit 2 **OC1FE**: Output Compare 1 fast enable

This bit decreases the latency between a trigger event and a transition on the timer output. It must be used in one-pulse mode (OPM bit set in TIMx\_CR1 register), to have the output pulse starting as soon as possible after the starting trigger.

0: CC1 behaves normally depending on counter and CCR1 values even when the trigger is ON. The minimum delay to activate CC1 output when an edge occurs on the trigger input is 5 clock cycles.

1: An active edge on the trigger input acts like a compare match on CC1 output. Then, OC is set to the compare level independently of the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OC1FE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 **CC1S[1:0]**: Capture/Compare 1 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC1 channel is configured as output

01: CC1 channel is configured as input, IC1 is mapped on TI1

Others: Reserved

*Note: CC1S bits are writable only when the channel is OFF (CC1E = '0' in TIMx\_CCER).*

### 32.7.8 TIMx capture/compare enable register (TIMx\_CCER)(x = 16 to 17)

Address offset: 0x20

Reset value: 0x0000

| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3     | 2     | 1    | 0    |
|------|------|------|------|------|------|------|------|------|------|------|------|-------|-------|------|------|
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | CC1NP | CC1NE | CC1P | CC1E |
|      |      |      |      |      |      |      |      |      |      |      |      | rw    | rw    | rw   | rw   |

Bits 15:4 Reserved, must be kept at reset value.

Bit 3 **CC1NP**: Capture/Compare 1 complementary output polarity

CC1 channel configured as output:

0: OC1N active high

1: OC1N active low

CC1 channel configured as input:

This bit is used in conjunction with CC1P to define the polarity of TI1FP1 and TI2FP1. Refer to the description of CC1P.

*Note: This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx\_BDTR register) and CC1S="00" (the channel is configured in output).*

*On channels that have a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx\_CR2 register then the CC1NP active bit takes the new value from the preloaded bit only when a commutation event is generated.*

Bit 2 **CC1NE**: Capture/Compare 1 complementary output enable

0: Off - OC1N is not active. OC1N level is then function of MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.

1: On - OC1N signal is output on the corresponding output pin depending on MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.

Bit 1 **CC1P**: Capture/Compare 1 output polarity

0: OC1 active high (output mode) / Edge sensitivity selection (input mode, see below)

1: OC1 active low (output mode) / Edge sensitivity selection (input mode, see below)

**When CC1 channel is configured as input**, both CC1NP/CC1P bits select the active polarity of TI1FP1 and TI2FP1 for trigger or capture operations.

CC1NP=0, CC1P=0: non-inverted/rising edge. The circuit is sensitive to TIxFP1 rising edge (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger operation in gated mode or encoder mode).

CC1NP=0, CC1P=1: inverted/falling edge. The circuit is sensitive to TIxFP1 falling edge (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is inverted (trigger operation in gated mode or encoder mode).

CC1NP=1, CC1P=1: non-inverted/both edges/ The circuit is sensitive to both TIxFP1 rising and falling edges (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger operation in gated mode). This configuration must not be used in encoder mode.

CC1NP=1, CC1P=0: this configuration is reserved, it must not be used.

*Note: This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx\_BDTR register).*

*On channels that have a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx\_CR2 register then the CC1P active bit takes the new value from the preloaded bit only when a Commutation event is generated.*

Bit 0 **CC1E**: Capture/Compare 1 output enable

0: Capture mode disabled / OC1 is not active (see below)

1: Capture mode enabled / OC1 signal is output on the corresponding output pin

**When CC1 channel is configured as output**, the OC1 level depends on MOE, OSSI, OSSR, OIS1, OIS1N and CC1NE bits, regardless of the CC1E bits state. Refer to [Table 209](#) for details.

**Table 209. Output control bits for complementary OCx and OCxN channels with break feature (TIM16/17)**

| Control bits |          |          |          |           | Output states <sup>(1)</sup>                                                                                                                                                                                                                           |                                                                         |
|--------------|----------|----------|----------|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------|
| MOE bit      | OSSI bit | OSSR bit | CCxE bit | CCxNE bit | OCx output state                                                                                                                                                                                                                                       | OCxN output state                                                       |

|              |          |          | 1        | 1         |                                                                                                                                                                                                                                                        |                                                                         |

1. When both outputs of a channel are not used (control taken over by GPIO controller), the OISx, OISxN, CCxP and CCxNP bits must be kept cleared.

**Note:** *The state of the external I/O pins connected to the complementary OCx and OCxN channels depends on the OCx and OCxN channel state and GPIO control and alternate function registers.*

### 32.7.9 TIMx counter (TIMx\_CNT)(x = 16 to 17)

Address offset: 0x24

Reset value: 0x0000 0000

|            |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|------------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| 31         | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| UIF<br>CPY | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. |
| r          |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| 15         | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| CNT[15:0]  |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| rW         | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   |

Bit 31 **UIFCPY**: UIF Copy

This bit is a read-only copy of the UIF bit of the TIMx\_ISR register. If the UIFREMAP bit in TIMx\_CR1 is reset, bit 31 is reserved and read as 0.

Bits 30:16 Reserved, must be kept at reset value.

Bits 15:0 **CNT[15:0]**: Counter value

### 32.7.10 TIMx prescaler (TIMx\_PSC)(x = 16 to 17)

Address offset: 0x28

Reset value: 0x0000

|           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 15        | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| PSC[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW        | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 15:0 **PSC[15:0]**: Prescaler value

The counter clock frequency (CK\_CNT) is equal to  $f_{CK\_PSC} / (PSC[15:0] + 1)$ .

PSC contains the value to be loaded in the active prescaler register at each update event (including when the counter is cleared through UG bit of TIMx\_EGR register or through trigger controller when configured in “reset mode”).

### 32.7.11 TIMx auto-reload register (TIMx\_ARR)(x = 16 to 17)

Address offset: 0x2C

Reset value: 0xFFFF

|           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 15        | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| ARR[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW        | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 15:0 **ARR[15:0]**: Auto-reload value

ARR is the value to be loaded in the actual auto-reload register.

Refer to the [Section 32.5.1: Time-base unit on page 1078](#) for more details about ARR update and behavior.

The counter is blocked while the auto-reload value is null.

### 32.7.12 TIMx repetition counter register (TIMx\_RCR)(x = 16 to 17)

Address offset: 0x30

Reset value: 0x0000

| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7        | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|------|------|------|------|------|------|------|------|----------|-----|-----|-----|-----|-----|-----|-----|
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | REP[7:0] |     |     |     |     |     |     |     |
|      |      |      |      |      |      |      |      | r/w      | r/w | r/w | r/w | r/w | r/w | r/w | r/w |

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **REP[7:0]**: Repetition counter value

These bits allow the user to set-up the update rate of the compare registers (i.e. periodic transfers from preload to active registers) when preload registers are enable, as well as the update interrupt generation rate, if this interrupt is enable.

Each time the REP\_CNT related downcounter reaches zero, an update event is generated and it restarts counting from REP value. As REP\_CNT is reloaded with REP value only at the repetition update event U\_RC, any write to the TIMx\_RCR register is not taken in account until the next repetition update event.

It means in PWM mode (REP+1) corresponds to the number of PWM periods in edge-aligned mode.

### 32.7.13 TIMx capture/compare register 1 (TIMx\_CCR1)(x = 16 to 17)

Address offset: 0x34

Reset value: 0x0000

| 15         | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| CCR1[15:0] |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
| r/w        | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w |

Bits 15:0 **CCR1[15:0]**: Capture/Compare 1 value

**If channel CC1 is configured as output:**

CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIMx\_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx\_CNT and signaled on OC1 output.

**If channel CC1 is configured as input:**

CCR1 is the counter value transferred by the last input capture 1 event (IC1).

**32.7.14 TIMx break and dead-time register (TIMx\_BDTR)(x = 16 to 17)**

Address offset: 0x44

Reset value: 0x0000 0000

|      |      |      |      |      |      |           |      |          |      |      |      |      |      |      |      |
|------|------|------|------|------|------|-----------|------|----------|------|------|------|------|------|------|------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25        | 24   | 23       | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Res. | Res. | Res. | Res. | Res. | Res. | Res.      | Res. | Res.     | Res. | Res. | Res. | Res. | Res. | Res. | Res. |
|      |      |      |      |      |      |           |      |          |      |      |      |      |      |      |      |
| 15   | 14   | 13   | 12   | 11   | 10   | 9         | 8    | 7        | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| MOE  | AOE  | BKP  | BKE  | OSSR | OSSI | LOCK[1:0] |      | DTG[7:0] |      |      |      |      |      |      |      |
| rw   | rw   | rw   | rw   | rw   | rw   | rw        | rw   | rw       | rw   | rw   | rw   | rw   | rw   | rw   | rw   |

**Note:** As the AOE, BKP, BKE, OSSI, OSSR and DTG[7:0] bits may be write-locked depending on the LOCK configuration, it may be necessary to configure all of them during the first write access to the TIMx\_BDTR register.

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:16 Reserved, must be kept at reset value.

Bit 15 **MOE**: Main output enable

This bit is cleared asynchronously by hardware as soon as the break input is active. It is set by software or automatically depending on the AOE bit. It is acting only on the channels which are configured in output.

0: OC and OCN outputs are disabled or forced to idle state depending on the OSSI bit.

1: OC and OCN outputs are enabled if their respective enable bits are set (CCxE, CCxNE in TIMx\_CCER register)

See OC/OCN enable description for more details ([Section 32.7.8: TIMx capture/compare enable register \(TIMx\\_CCER\)\(x = 16 to 17\) on page 1145](#)).

Bit 14 **AOE**: Automatic output enable

0: MOE can be set only by software

1: MOE can be set by software or automatically at the next update event (if the break input is not be active)

**Note:** This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).

Bit 13 **BKP**: Break polarity

0: Break input BRK is active low

1: Break input BRK is active high

**Note:** This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).

Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 12 **BKE**: Break enable

0: Break inputs (BRK and CCS clock failure event) disabled

1: Break inputs (BRK and CCS clock failure event) enabled

**Note:** This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).

Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 11 **OSSR**: Off-state selection for Run mode

This bit is used when MOE=1 on channels that have a complementary output which are configured as outputs. OSSR is not implemented if no complementary output is implemented in the timer.

See OC/OCN enable description for more details ([Section 32.7.8: TIMx capture/compare enable register \(TIMx\\_CCER\)\(x = 16 to 17\) on page 1145](#)).

0: When inactive, OC/OCN outputs are disabled (the timer releases the output control which is taken over by the GPIO, which forces a Hi-Z state)

1: When inactive, OC/OCN outputs are enabled with their inactive level as soon as CCxE=1 or CCxNE=1 (the output is still controlled by the timer).

*Note: This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx\_BDTR register).*

Bit 10 **OSSI**: Off-state selection for Idle mode

This bit is used when MOE=0 on channels configured as outputs.

See OC/OCN enable description for more details ([Section 32.7.8: TIMx capture/compare enable register \(TIMx\\_CCER\)\(x = 16 to 17\) on page 1145](#)).

0: When inactive, OC/OCN outputs are disabled (OC/OCN enable output signal=0)

1: When inactive, OC/OCN outputs are forced first with their idle level as soon as CCxE=1 or CCxNE=1. OC/OCN enable output signal=1)

*Note: This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx\_BDTR register).*

Bits 9:8 **LOCK[1:0]**: Lock configuration

These bits offer a write protection against software errors.

00: LOCK OFF - No bit is write protected

01: LOCK Level 1 = DTG bits in TIMx\_BDTR register, OISx and OISxN bits in TIMx\_CR2 register and BKE/BKP/AOE bits in TIMx\_BDTR register can no longer be written.

10: LOCK Level 2 = LOCK Level 1 + CC Polarity bits (CCxP/CCxNP bits in TIMx\_CCER register, as long as the related channel is configured in output through the CCxS bits) as well as OSSR and OSSI bits can no longer be written.

11: LOCK Level 3 = LOCK Level 2 + CC Control bits (OCxM and OCxPE bits in TIMx\_CCMRx registers, as long as the related channel is configured in output through the CCxS bits) can no longer be written.

*Note: The LOCK bits can be written only once after the reset. Once the TIMx\_BDTR register has been written, their content is frozen until the next reset.*

Bits 7:0 **DTG[7:0]**: Dead-time generator setup

This bit-field defines the duration of the dead-time inserted between the complementary outputs. DT correspond to this duration.

$DTG[7:5] = 0xx \Rightarrow DT = DTG[7:0] \times t_{dtg}$  with  $t_{dtg} = t_{DTS}$

$DTG[7:5] = 10x \Rightarrow DT = (64 + DTG[5:0]) \times t_{dtg}$  with  $t_{dtg} = 2 \times t_{DTS}$

$DTG[7:5] = 110 \Rightarrow DT = (32 + DTG[4:0]) \times t_{dtg}$  with  $t_{dtg} = 8 \times t_{DTS}$

$DTG[7:5] = 111 \Rightarrow DT = (32 + DTG[4:0]) \times t_{dtg}$  with  $t_{dtg} = 16 \times t_{DTS}$

Example if  $t_{DTS} = 125$  ns (8 MHz), dead-time possible values are:

0 to 15875 ns by 125 ns steps,

16  $\mu$ s to 31750 ns by 250 ns steps,

32  $\mu$ s to 63  $\mu$ s by 1  $\mu$ s steps,

64  $\mu$ s to 126  $\mu$ s by 2  $\mu$ s steps

*Note: This bit-field can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx\_BDTR register).*

**32.7.15 TIMx DMA control register (TIMx\_DCR)(x = 16 to 17)**

Address offset: 0x48

Reset value: 0x0000

| 15   | 14   | 13   | 12       | 11 | 10 | 9  | 8  | 7    | 6    | 5    | 4        | 3  | 2  | 1  | 0  |
|------|------|------|----------|----|----|----|----|------|------|------|----------|----|----|----|----|
| Res. | Res. | Res. | DBL[4:0] |    |    |    |    | Res. | Res. | Res. | DBA[4:0] |    |    |    |    |
|      |      |      | rw       | rw | rw | rw | rw |      |      |      | rw       | rw | rw | rw | rw |

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:8 **DBL[4:0]**: DMA burst length

This 5-bit field defines the length of DMA transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIMx\_DMAR address), i.e. the number of transfers. Transfers can be in half-words or in bytes (see example below).

00000: 1 transfer,

00001: 2 transfers,

00010: 3 transfers,

...

10001: 18 transfers.

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **DBA[4:0]**: DMA base address

This 5-bit field defines the base-address for DMA transfers (when read/write access are done through the TIMx\_DMAR address). DBA is defined as an offset starting from the address of the TIMx\_CR1 register.

Example:

00000: TIMx\_CR1,

00001: TIMx\_CR2,

00010: TIMx\_SMCR,

...

**Example:** Let us consider the following transfer: DBL = 7 transfers and DBA = TIMx\_CR1. In this case the transfer is done to/from 7 registers starting from the TIMx\_CR1 address.

**32.7.16 TIMx DMA address for full transfer (TIMx\_DMAR)(x = 16 to 17)**

Address offset: 0x4C

Reset value: 0x0000

| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| DMAB[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw         | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 15:0 **DMAB[15:0]**: DMA register for burst accesses

A read or write operation to the DMAR register accesses the register located at the address  
 $(\text{TIMx\_CR1 address}) + (\text{DBA} + \text{DMA index}) \times 4$

where TIMx\_CR1 address is the address of the control register 1, DBA is the DMA base address configured in TIMx\_DCR register, DMA index is automatically controlled by the DMA transfer, and ranges from 0 to DBL (DBL configured in TIMx\_DCR).

Bits 31:12 Reserved, must be kept at reset value.

Bit 11 **BKCOMP2P**: BRK COMP2 input polarity

This bit selects the COMP2 input sensitivity. It must be programmed together with the BKP polarity bit.

0: COMP2 input is active low

1: COMP2 input is active high

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

Bit 10 **BKCOMP1P**: BRK COMP1 input polarity

This bit selects the COMP1 input sensitivity. It must be programmed together with the BKP polarity bit.

0: COMP1 input is active low

1: COMP1 input is active high

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

Bit 9 **BKINP**: BRK BKIN input polarity

This bit selects the BKIN alternate function input sensitivity. It must be programmed together with the BKP polarity bit.

0: BKIN input is active low

1: BKIN input is active high

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

Bit 8 **BKDF1BK1E**: BRK dfsdm1\_break[1] enable

This bit enables the dfsdm1\_break[1] for the timer's BRK input. dfsdm1\_break[1] output is 'ORed' with the other BRK sources.

0: dfsdm1\_break[1] input disabled

1: dfsdm1\_break[1] input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

Bits 7:3 Reserved, must be kept at reset value.

Bit 2 **BKCOMP2E**: BRK COMP2 enable

This bit enables the COMP2 for the timer's BRK input. COMP2 output is 'ORed' with the other BRK sources.

0: COMP2 input disabled

1: COMP2 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

Bit 1 **BKCOMP1E**: BRK COMP1 enable

This bit enables the COMP1 for the timer's BRK input. COMP1 output is 'ORed' with the other BRK sources.

0: COMP1 input disabled

1: COMP1 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

Bit 0 **BKINE**: BRK BKIN input enable

This bit enables the BKIN alternate function input for the timer's BRK input. BKIN input is 'ORed' with the other BRK sources.

0: BKIN input disabled

1: BKIN input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

This bit enables the dfsdm1\_break[2] for the timer's BRK input. dfsdm1\_break[2] output is 'ORed' with the other BRK sources.

0: dfsdm1\_break[2] input disabled

1: dfsdm1\_break[2] input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

Bits 7:3 Reserved, must be kept at reset value.

**Bit 2 BKCOMP2E:** BRK COMP2 enable

This bit enables the COMP2 for the timer's BRK input. COMP2 output is 'ORed' with the other BRK sources.

0: COMP2 input disabled

1: COMP2 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

**Bit 1 BKCOMP1E:** BRK COMP1 enable

This bit enables the COMP1 for the timer's BRK input. COMP1 output is 'ORed' with the other BRK sources.

0: COMP1 input disabled

1: COMP1 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

**Bit 0 BKINE:** BRK BKIN input enable

This bit enables the BKIN alternate function input for the timer's BRK input. BKIN input is 'ORed' with the other BRK sources.

0: BKIN input disabled

1: BKIN input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

## 32.7.21 TIM16/TIM17 register map

TIM16/TIM17 registers are mapped as 16-bit addressable registers as described in the table below:

Table 210. TIM16/TIM17 register map and reset values

| Offset | Register name                     | 31             | 30  | 29  | 28  | 27  | 26  | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16      | 15        | 14  | 13  | 12  | 11      | 10  | 9            | 8               | 7             | 6     | 5   | 4   | 3     | 2             | 1             | 0    |   |   |   |

Refer to [Section 2.2 on page 75](#) for the register boundary addresses.

## 33 Basic timers (TIM6/TIM7)

### 33.1 TIM6/TIM7 introduction

The basic timers TIM6 and TIM7 consist of a 16-bit auto-reload counter driven by a programmable prescaler.

They may be used as generic timers for time base generation but they are also specifically used to drive the digital-to-analog converter (DAC). In fact, the timers are internally connected to the DAC and are able to drive it through their trigger outputs.

The timers are completely independent, and do not share any resources.

### 33.2 TIM6/TIM7 main features

Basic timer (TIM6/TIM7) features include:

- 16-bit auto-reload upcounter
- 16-bit programmable prescaler used to divide (also “on the fly”) the counter clock frequency by any factor between 1 and 65535
- Synchronization circuit to trigger the DAC
- Interrupt/DMA generation on the update event: counter overflow

**Figure 368. Basic timer block diagram**

## 33.3 TIM6/TIM7 functional description

### 33.3.1 Time-base unit

The main block of the programmable timer is a 16-bit upcounter with its related auto-reload register. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:

- Counter Register (TIMx\_CNT)
- Prescaler Register (TIMx\_PSC)
- Auto-Reload Register (TIMx\_ARR)

The auto-reload register is preloaded. The preload register is accessed each time an attempt is made to write or read the auto-reload register. The contents of the preload register are transferred into the shadow register permanently or at each update event UEV, depending on the auto-reload preload enable bit (ARPE) in the TIMx\_CR1 register. The update event is sent when the counter reaches the overflow value and if the UDIS bit equals 0 in the TIMx\_CR1 register. It can also be generated by software. The generation of the update event is described in detail for each configuration.

The counter is clocked by the prescaler output CK\_CNT, which is enabled only when the counter enable bit (CEN) in the TIMx\_CR1 register is set.

Note that the actual counter enable signal CNT\_EN is set 1 clock cycle after CEN.

#### Prescaler description

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx\_PSC register). It can be changed on the fly as the TIMx\_PSC control register is buffered. The new prescaler ratio is taken into account at the next update event.

[Figure 369](#) and [Figure 370](#) give some examples of the counter behavior when the prescaler ratio is changed on the fly.

Figure 369. Counter timing diagram with prescaler division change from 1 to 2

Figure 370. Counter timing diagram with prescaler division change from 1 to 4

### 33.3.2 Counting mode

The counter counts from 0 to the auto-reload value (contents of the TIMx\_ARR register), then restarts from 0 and generates a counter overflow event.

An update event can be generated at each counter overflow or by setting the UG bit in the TIMx\_EGR register (by software or by using the slave mode controller).

The UEV event can be disabled by software by setting the UDIS bit in the TIMx\_CR1 register. This avoids updating the shadow registers while writing new values into the preload registers. In this way, no update event occurs until the UDIS bit has been cleared, however, the counter and the prescaler counter both restart from 0 (but the prescale rate does not change). In addition, if the URS (update request selection) bit in the TIMx\_CR1 register is set, setting the UG bit generates an update event UEV, but the UIF flag is not set (so no interrupt or DMA request is sent).

When an update event occurs, all the registers are updated and the update flag (UIF bit in the TIMx\_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (contents of the TIMx\_PSC register)
- The auto-reload shadow register is updated with the preload value (TIMx\_ARR)

The following figures show some examples of the counter behavior for different clock frequencies when TIMx\_ARR = 0x36.

**Figure 371. Counter timing diagram, internal clock divided by 1**

Figure 373. Counter timing diagram, internal clock divided by 4

Figure 374. Counter timing diagram, internal clock divided by N

Figure 375. Counter timing diagram, update event when ARPE = 0 (TIMx\_ARR not preloaded)

**Figure 376. Counter timing diagram, update event when ARPE=1 (TIMx\_ARR preloaded)**

### 33.3.3 UIF bit remapping

The IUFREMAP bit in the TIMx\_CR1 register forces a continuous copy of the Update Interrupt Flag UIF into the timer counter register's bit 31 (TIMxCNT[31]). This allows to atomically read both the counter value and a potential roll-over condition signaled by the UIFCPY flag. In particular cases, it can ease the calculations by avoiding race conditions caused for instance by a processing shared between a background task (counter reading) and an interrupt (Update Interrupt).

There is no latency between the assertions of the UIF and UIFCPY flags.

### 33.3.4 Clock source

The counter clock is provided by the Internal clock (CK\_INT) source.

The CEN (in the TIMx\_CR1 register) and UG bits (in the TIMx\_EGR register) are actual control bits and can be changed only by software (except for UG that remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock CK\_INT.

[Figure 377](#) shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.

Figure 377. Control circuit in normal mode, internal clock divided by 1

### 33.3.5 Debug mode

When the microcontroller enters the debug mode (Cortex®-M4 core - halted), the TIMx counter either continues to work normally or stops, depending on the DBG\_TIMx\_STOP configuration bit in the DBG module. For more details, refer to [Section 48.16.2: Debug support for timers, RTC, watchdog, bxCAN and I<sup>2</sup>C](#).

## 33.4 TIM6/TIM7 registers

Refer to [Section 1.2 on page 69](#) for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

### 33.4.1 TIMx control register 1 (TIMx\_CR1)(x = 6 to 7)

Address offset: 0x00

Reset value: 0x0000

| 15   | 14   | 13   | 12   | 11           | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3   | 2   | 1    | 0   |
|------|------|------|------|--------------|------|------|------|------|------|------|------|-----|-----|------|-----|
| Res. | Res. | Res. | Res. | UIFRE<br>MAP | Res. | Res. | Res. | ARPE | Res. | Res. | Res. | OPM | URS | UDIS | CEN |
|      |      |      |      | rw           |      |      |      | rw   |      |      |      | rw  | rw  | rw   | rw  |

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 **UIFREMAP**: UIF status bit remapping

0: No remapping. UIF status bit is not copied to TIMx\_CNT register bit 31.

1: Remapping enabled. UIF status bit is copied to TIMx\_CNT register bit 31.

Bits 10:8 Reserved, must be kept at reset value.

Bit 7 **ARPE**: Auto-reload preload enable

0: TIMx\_ARR register is not buffered.

1: TIMx\_ARR register is buffered.

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 **OPM**: One-pulse mode

0: Counter is not stopped at update event

1: Counter stops counting at the next update event (clearing the CEN bit).

Bit 2 **URS**: Update request source

This bit is set and cleared by software to select the UEV event sources.

0: Any of the following events generates an update interrupt or DMA request if enabled.

These events can be:

- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller

1: Only counter overflow/underflow generates an update interrupt or DMA request if enabled.

Bit 1 **UDIS**: Update disable

This bit is set and cleared by software to enable/disable UEV event generation.

0: UEV enabled. The Update (UEV) event is generated by one of the following events:

- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller

Buffered registers are then loaded with their preload values.

1: UEV disabled. The Update event is not generated, shadow registers keep their value (ARR, PSC). However the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.

Bit 0 **CEN**: Counter enable

0: Counter disabled

1: Counter enabled

*Note: Gated mode can work only if the CEN bit has been previously set by software.*

*However trigger mode can set the CEN bit automatically by hardware.*

CEN is cleared automatically in one-pulse mode, when an update event occurs.

### 33.4.2 TIMx control register 2 (TIMx\_CR2)(x = 6 to 7)

Address offset: 0x04

Reset value: 0x0000

| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6        | 5  | 4  | 3    | 2    | 1    | 0    |
|------|------|------|------|------|------|------|------|------|----------|----|----|------|------|------|------|
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | MMS[2:0] |    |    | Res. | Res. | Res. | Res. |
|      |      |      |      |      |      |      |      |      | rw       | rw | rw |      |      |      |      |

Bits 15:7 Reserved, must be kept at reset value.

Bits 6:4 **MMS[2:0]**: Master mode selection

These bits are used to select the information to be sent in master mode to slave timers for synchronization (TRGO). The combination is as follows:

000: **Reset** - the UG bit from the TIMx\_EGR register is used as a trigger output (TRGO). If reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on TRGO is delayed compared to the actual reset.

001: **Enable** - the Counter enable signal, CNT\_EN, is used as a trigger output (TRGO). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic OR between CEN control bit and the trigger input when configured in gated mode.

When the Counter Enable signal is controlled by the trigger input, there is a delay on TRGO, except if the master/slave mode is selected (see the MSM bit description in the TIMx\_SMCR register).

010: **Update** - The update event is selected as a trigger output (TRGO). For instance a master timer can then be used as a prescaler for a slave timer.

*Note: The clock of the slave timer or ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.*

Bits 3:0 Reserved, must be kept at reset value.

### 33.4.3 TIMx DMA/Interrupt enable register (TIMx\_DIER)(x = 6 to 7)

Address offset: 0x0C

Reset value: 0x0000

| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8   | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0   |
|------|------|------|------|------|------|------|-----|------|------|------|------|------|------|------|-----|
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | UDE | Res. | Res. | Res. | Res. | Res. | Res. | Res. | UIE |
|      |      |      |      |      |      |      | rw  |      |      |      |      |      |      |      | rw  |

Bits 15:9 Reserved, must be kept at reset value.

Bit 8 **UDE**: Update DMA request enable

0: Update DMA request disabled.

1: Update DMA request enabled.

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 **UIE**: Update interrupt enable

0: Update interrupt disabled.

1: Update interrupt enabled.

**33.4.4 TIMx status register (TIMx\_SR)(x = 6 to 7)**

Address offset: 0x10

Reset value: 0x0000

| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0     |
|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|-------|
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | UIF   |
|      |      |      |      |      |      |      |      |      |      |      |      |      |      |      | rc_w0 |

Bits 15:1 Reserved, must be kept at reset value.

Bit 0 **UIF**: Update interrupt flag

This bit is set by hardware on an update event. It is cleared by software.

0: No update occurred.

1: Update interrupt pending. This bit is set by hardware when the registers are updated:

- At overflow or underflow regarding the repetition counter value and if UDIS = 0 in the TIMx\_CR1 register.
- When CNT is reinitialized by software using the UG bit in the TIMx\_EGR register, if URS = 0 and UDIS = 0 in the TIMx\_CR1 register.

**33.4.5 TIMx event generation register (TIMx\_EGR)(x = 6 to 7)**

Address offset: 0x14

Reset value: 0x0000

| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0  |
|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|----|
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | UG |
|      |      |      |      |      |      |      |      |      |      |      |      |      |      |      | w  |

Bits 15:1 Reserved, must be kept at reset value.

Bit 0 **UG**: Update generation

This bit can be set by software, it is automatically cleared by hardware.

0: No action.

1: Re-initializes the timer counter and generates an update of the registers. Note that the prescaler counter is cleared too (but the prescaler ratio is not affected).

**33.4.6 TIMx counter (TIMx\_CNT)(x = 6 to 7)**

Address offset: 0x24

Reset value: 0x0000 0000

| 31         | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |

| rW         | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   |

Bit 31 **UIFCPY**: UIF Copy

This bit is a read-only copy of the UIF bit of the TIMx\_ISR register. If the UIFREMAP bit in TIMx\_CR1 is reset, bit 31 is reserved and read as 0.

Bits 30:16 Reserved, must be kept at reset value.

Bits 15:0 **CNT[15:0]**: Counter value

### 33.4.7 TIMx prescaler (TIMx\_PSC)(x = 6 to 7)

Address offset: 0x28

Reset value: 0x0000

| 15        | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|-----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| PSC[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw        | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 15:0 **PSC[15:0]**: Prescaler value

The counter clock frequency CK\_CNT is equal to  $f_{CK\_PSC} / (PSC[15:0] + 1)$ .

PSC contains the value to be loaded into the active prescaler register at each update event.  
(including when the counter is cleared through UG bit of TIMx\_EGR register or through trigger controller when configured in “reset mode”).

### 33.4.8 TIMx auto-reload register (TIMx\_ARR)(x = 6 to 7)

Address offset: 0x2C

Reset value: 0xFFFF

| 15        | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|-----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| ARR[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw        | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 15:0 **ARR[15:0]**: Prescaler value

ARR is the value to be loaded into the actual auto-reload register.

Refer to [Section 33.3.1: Time-base unit on page 1161](#) for more details about ARR update and behavior.

The counter is blocked while the auto-reload value is null.

### 33.4.9 TIMx register map

TIMx registers are mapped as 16-bit addressable registers as described in the table below:

**Table 211. TIMx register map and reset values**

| Offset    | Register name | 31             | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   | 15        | 14   | 13   | 12   | 11      | 10   | 9    | 8    | 7    | 6         | 5    | 4    | 3    | 2    | 1    | 0    |     |
|-----------|---------------|----------------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|-----------|------|------|------|---------|------|------|------|------|-----------|------|------|------|------|------|------|-----|

Refer to [Section 2.2 on page 75](#) for the register boundary addresses.

## 34 Low-power timer (LPTIM)

### 34.1 Introduction

The LPTIM is a 16-bit timer that benefits from the ultimate developments in power consumption reduction. Thanks to its diversity of clock sources, the LPTIM is able to keep running in all power modes except for Standby mode. Given its capability to run even with no internal clock source, the LPTIM can be used as a “Pulse Counter” which can be useful in some applications. Also, the LPTIM capability to wake up the system from low-power modes, makes it suitable to realize “Timeout functions” with extremely low power consumption.

The LPTIM introduces a flexible clock scheme that provides the needed functionalities and performance, while minimizing the power consumption.

### 34.2 LPTIM main features

- 16 bit upcounter
- 3-bit prescaler with 8 possible dividing factors (1,2,4,8,16,32,64,128)
- Selectable clock
  - Internal clock sources: configurable internal clock source (see RCC section)
  - External clock source over LPTIM input (working with no embedded oscillator running, used by Pulse Counter application)
- 16 bit ARR autoreload register
- 16 bit compare register
- Continuous/One-shot mode
- Selectable software/hardware input trigger
- Programmable Digital Glitch filter
- Configurable output: Pulse, PWM
- Configurable I/O polarity
- Encoder mode

### 34.3 LPTIM implementation

**Table 212** describes LPTIM implementation on STM32L47x/L48x/L49x/L4Ax devices: the full set of features is implemented in LPTIM1. LPTIM2 supports a smaller set of features, but is otherwise identical to LPTIM1.

### Table 212. STM32L47x/L48x/L49x/L4Ax LPTIM features

| LPTIM modes/features <sup>(1)</sup> | LPTIM1 | LPTIM2 |
|-------------------------------------|--------|--------|
| Encoder mode                        | X      | -      |

---

1.  $X = \text{supported}$ .

### 34.4 LPTIM functional description

### 34.4.1 LPTIM block diagram

**Figure 378. Low-power timer block diagram**

### 34.4.2 LPTIM trigger mapping

The LPTIM external trigger connections are detailed hereafter:

**Table 213. LPTIM1 external trigger connection**

| TRIGSEL         | External trigger          |
|-----------------|---------------------------|
| lptim_ext_trig0 | GPIO                      |
| lptim_ext_trig1 | RTC alarm A               |
| lptim_ext_trig2 | RTC alarm B               |
| lptim_ext_trig3 | RTC_TAMP1 input detection |
| lptim_ext_trig4 | RTC_TAMP2 input detection |
| lptim_ext_trig5 | RTC_TAMP3 input detection |
| lptim_ext_trig6 | COMP1_OUT                 |
| lptim_ext_trig7 | COMP2_OUT                 |

**Table 214. LPTIM2 external trigger connection**

| TRIGSEL         | External trigger          |
|-----------------|---------------------------|
| lptim_ext_trig0 | GPIO                      |
| lptim_ext_trig1 | RTC alarm A               |
| lptim_ext_trig2 | RTC alarm B               |
| lptim_ext_trig3 | RTC_TAMP1 input detection |
| lptim_ext_trig4 | RTC_TAMP2 input detection |
| lptim_ext_trig5 | RTC_TAMP3 input detection |
| lptim_ext_trig6 | COMP1_OUT                 |
| lptim_ext_trig7 | COMP2_OUT                 |

### 34.4.3 LPTIM reset and clocks

The LPTIM can be clocked using several clock sources. It can be clocked using an internal clock signal which can be any configurable internal clock source selectable through the RCC (see RCC section for more details). Also, the LPTIM can be clocked using an external clock signal injected on its external Input1. When clocked with an external clock source, the LPTIM may run in one of these two possible configurations:

- The first configuration is when the LPTIM is clocked by an external signal but in the same time an internal clock signal is provided to the LPTIM from configurable internal clock source (see RCC section).
- The second configuration is when the LPTIM is solely clocked by an external clock source through its external Input1. This configuration is the one used to realize Timeout function or Pulse counter function when all the embedded oscillators are turned off after entering a low-power mode.

Programming the CKSEL and COUNTMODE bits allows controlling whether the LPTIM will use an external clock source or an internal one.

When configured to use an external clock source, the CKPOL bits are used to select the external clock signal active edge. If both edges are configured to be active ones, an internal clock signal should also be provided (first configuration). In this case, the internal clock signal frequency should be at least four times higher than the external clock signal frequency.

### 34.4.4 Glitch filter

The LPTIM inputs, either external (mapped to GPIOs) or internal (mapped on the chip-level to other embedded peripherals), are protected with digital filters that prevent any glitches and noise perturbations to propagate inside the LPTIM. This is in order to prevent spurious counts or triggers.

Before activating the digital filters, an internal clock source should first be provided to the LPTIM. This is necessary to guarantee the proper operation of the filters.

The digital filters are divided into two groups:

- The first group of digital filters protects the LPTIM external inputs. The digital filters sensitivity is controlled by the CKFLT bits
- The second group of digital filters protects the LPTIM internal trigger inputs. The digital filters sensitivity is controlled by the TRGFLT bits.

**Note:** *The digital filters sensitivity is controlled by groups. It is not possible to configure each digital filter sensitivity separately inside the same group.*

The filter sensitivity acts on the number of consecutive equal samples that should be detected on one of the LPTIM inputs to consider a signal level change as a valid transition. [Figure 379](#) shows an example of glitch filter behavior in case of a 2 consecutive samples programmed.

**Figure 379. Glitch filter timing diagram**

**Note:** *In case no internal clock signal is provided, the digital filter must be deactivated by setting the CKFLT and TRGFLT bits to '0'. In that case, an external analog filter may be used to protect the LPTIM external inputs against glitches.*

### 34.4.5 Prescaler

The LPTIM 16-bit counter is preceded by a configurable power-of-2 prescaler. The prescaler division ratio is controlled by the PRESC[2:0] 3-bit field. The table below lists all the possible division ratios:

**Table 215. Prescaler division ratios**

| programming | dividing factor |
|-------------|-----------------|
| 000         | /1              |
| 001         | /2              |
| 010         | /4              |
| 011         | /8              |
| 100         | /16             |
| 101         | /32             |
| 110         | /64             |
| 111         | /128            |

### 34.4.6 Trigger multiplexer

The LPTIM counter may be started either by software or after the detection of an active edge on one of the 8 trigger inputs.

TRIGEN[1:0] is used to determine the LPTIM trigger source:

- When TRIGEN[1:0] equals '00', The LPTIM counter is started as soon as one of the CNTSTRT or the SNGSTRT bits is set by software. The three remaining possible values for the TRIGEN[1:0] are used to configure the active edge used by the trigger inputs. The LPTIM counter starts as soon as an active edge is detected.
- When TRIGEN[1:0] is different than '00', TRIGSEL[2:0] is used to select which of the 8 trigger inputs is used to start the counter.

The external triggers are considered asynchronous signals for the LPTIM. So after a trigger detection, a two-counter-clock period latency is needed before the timer starts running due to the synchronization.

If a new trigger event occurs when the timer is already started it will be ignored (unless timeout function is enabled).

**Note:** *The timer must be enabled before setting the SNGSTRT/CNTSTRT bits. Any write on these bits when the timer is disabled will be discarded by hardware.*

**Note:** *When starting the counter by software (TRIGEN[1:0] = 00), there is a delay of 3 kernel clock cycles between the LPTIM\_CR register update (set one of SNGSTRT or CNTSTRT bits) and the effective start of the counter.*

### 34.4.7 Operating mode

The LPTIM features two operating modes:

- The Continuous mode: the timer is free running, the timer is started from a trigger event and never stops until the timer is disabled
- One-shot mode: the timer is started from a trigger event and stops when reaching the ARR value.

#### One-shot mode

To enable the one-shot counting, the SNGSTRT bit must be set.

A new trigger event will re-start the timer. Any trigger event occurring after the counter starts and before the counter reaches ARR will be discarded.

In case an external trigger is selected, each external trigger event arriving after the SNGSTRT bit is set, and after the counter register has stopped (contains zero value), will start the counter for a new one-shot counting cycle as shown in [Figure 380](#).

**Figure 380. LPTIM output waveform, single counting mode configuration**

Set-once mode activated:

It should be noted that when the WAVE bit-field in the LPTIM\_CFGR register is set, the Set-once mode is activated. In this case, the counter is only started once following the first trigger, and any subsequent trigger event is discarded as shown in [Figure 381](#).

**Figure 381. LPTIM output waveform, Single counting mode configuration and Set-once mode activated (WAVE bit is set)**

In case of software start (TRIGEN[1:0] = '00'), the SNGSTRT setting will start the counter for one-shot counting.

### Continuous mode

To enable the continuous counting, the CNTSTRT bit must be set.

In case an external trigger is selected, an external trigger event arriving after CNTSTRT is set will start the counter for continuous counting. Any subsequent external trigger event will be discarded as shown in [Figure 382](#).

In case of software start (TRIGEN[1:0] = '00'), setting CNTSTRT will start the counter for continuous counting.

**Figure 382. LPTIM output waveform, Continuous counting mode configuration**

SNGSTRT and CNTSTRT bits can only be set when the timer is enabled (The ENABLE bit is set to '1'). It is possible to change "on the fly" from One-shot mode to Continuous mode.

If the Continuous mode was previously selected, setting SNGSTRT will switch the LPTIM to the One-shot mode. The counter (if active) will stop as soon as it reaches ARR.

If the One-shot mode was previously selected, setting CNTSTRT will switch the LPTIM to the Continuous mode. The counter (if active) will restart as soon as it reaches ARR.

### 34.4.8 Timeout function

The detection of an active edge on one selected trigger input can be used to reset the LPTIM counter. This feature is controlled through the TIMOUT bit.

The first trigger event will start the timer, any successive trigger event will reset the counter and the timer will restart.

A low-power timeout function can be realized. The timeout value corresponds to the compare value; if no trigger occurs within the expected time frame, the MCU is waked-up by the compare match event.

### 34.4.9 Waveform generation

Two 16-bit registers, the LPTIM\_ARR (autoreload register) and LPTIM\_CMP (compare register), are used to generate several different waveforms on LPTIM output

The timer can generate the following waveforms:

- The PWM mode: the LPTIM output is set as soon as the counter value in LPTIM\_CNT exceeds the compare value in LPTIM\_CMP. The LPTIM output is reset as soon as a match occurs between the LPTIM\_ARR and the LPTIM\_CNT registers.
- The One-pulse mode: the output waveform is similar to the one of the PWM mode for the first pulse, then the output is permanently reset
- The Set-once mode: the output waveform is similar to the One-pulse mode except that the output is kept to the last signal level (depends on the output configured polarity).

The above described modes require that the LPTIM\_ARR register value be strictly greater than the LPTIM\_CMP register value.

The LPTIM output waveform can be configured through the WAVE bit as follow:

- Resetting the WAVE bit to '0' forces the LPTIM to generate either a PWM waveform or a One pulse waveform depending on which bit is set: CNTSTRT or SNGSTRT.
- Setting the WAVE bit to '1' forces the LPTIM to generate a Set-once mode waveform.

The WAVPOL bit controls the LPTIM output polarity. The change takes effect immediately, so the output default value will change immediately after the polarity is re-configured, even before the timer is enabled.

Signals with frequencies up to the LPTIM clock frequency divided by 2 can be generated.

[Figure 383](#) below shows the three possible waveforms that can be generated on the LPTIM output. Also, it shows the effect of the polarity change using the WAVPOL bit.

**Figure 383. Waveform generation**

### 34.4.10 Register update

The LPTIM\_ARR register and LPTIM\_CMP register are updated immediately after the APB bus write operation, or at the end of the current period if the timer is already started.

The PRELOAD bit controls how the LPTIM\_ARR and the LPTIM\_CMP registers are updated:

- When the PRELOAD bit is reset to '0', the LPTIM\_ARR and the LPTIM\_CMP registers are immediately updated after any write access.
- When the PRELOAD bit is set to '1', the LPTIM\_ARR and the LPTIM\_CMP registers are updated at the end of the current period, if the timer has been already started.

The LPTIM APB interface and the LPTIM kernel logic use different clocks, so there is some latency between the APB write and the moment when these values are available to the counter comparator. Within this latency period, any additional write into these registers must be avoided.

The ARROK flag and the CMPOK flag in the LPTIM\_ISR register indicate when the write operation is completed to respectively the LPTIM\_ARR register and the LPTIM\_CMP register.

After a write to the LPTIM\_ARR register or the LPTIM\_CMP register, a new write operation to the same register can only be performed when the previous write operation is completed. Any successive write before respectively the ARROK flag or the CMPOK flag be set, will lead to unpredictable results.

### 34.4.11 Counter mode

The LPTIM counter can be used to count external events on the LPTIM Input1 or it can be used to count internal clock cycles. The CKSEL and COUNTMODE bits control which source will be used for updating the counter.

In case the LPTIM is configured to count external events on Input1, the counter can be updated following a rising edge, falling edge or both edges depending on the value written to the CKPOL[1:0] bits.

The count modes below can be selected, depending on CKSEL and COUNTMODE values:

- CKSEL = 0: the LPTIM is clocked by an internal clock source
  - COUNTMODE = 0
 

The LPTIM is configured to be clocked by an internal clock source and the LPTIM counter is configured to be updated following each internal clock pulse.
  - COUNTMODE = 1
 

The LPTIM external Input1 is sampled with the internal clock provided to the LPTIM.

Consequently, in order not to miss any event, the frequency of the changes on the external Input1 signal should never exceed the frequency of the internal clock provided to the LPTIM. Also, the internal clock provided to the LPTIM must not be prescaled (PRESC[2:0] = 000).
- CKSEL = 1: the LPTIM is clocked by an external clock source
 

COUNTMODE value is don't care.

In this configuration, the LPTIM has no need for an internal clock source (except if the glitch filters are enabled). The signal injected on the LPTIM external Input1 is used as

system clock for the LPTIM. This configuration is suitable for operation modes where no embedded oscillator is enabled.

For this configuration, the LPTIM counter can be updated either on rising edges or falling edges of the input1 clock signal but not on both rising and falling edges.

Since the signal injected on the LPTIM external Input1 is also used to clock the LPTIM kernel logic, there is some initial latency (after the LPTIM is enabled) before the counter is incremented. More precisely, the first five active edges on the LPTIM external Input1 (after LPTIM is enable) are lost.

#### 34.4.12 Timer enable

The ENABLE bit located in the LPTIM\_CR register is used to enable/disable the LPTIM kernel logic. After setting the ENABLE bit, a delay of two counter clock is needed before the LPTIM is actually enabled.

The LPTIM\_CFGR and LPTIM\_IER registers must be modified only when the LPTIM is disabled.

#### 34.4.13 Encoder mode

This mode allows handling signals from quadrature encoders used to detect angular position of rotary elements. Encoder interface mode acts simply as an external clock with direction selection. This means that the counter just counts continuously between 0 and the auto-reload value programmed into the LPTIM\_ARR register (0 up to ARR or ARR down to 0 depending on the direction). Therefore LPTIM\_ARR must be configured before starting the counter. From the two external input signals, Input1 and Input2, a clock signal is generated to clock the LPTIM counter. The phase between those two signals determines the counting direction.

The Encoder mode is only available when the LPTIM is clocked by an internal clock source. The signals frequency on both Input1 and Input2 inputs must not exceed the LPTIM internal clock frequency divided by 4. This is mandatory in order to guarantee a proper operation of the LPTIM.

Direction change is signaled by the two Down and Up flags in the LPTIM\_ISR register. Also, an interrupt can be generated for both direction change events if enabled through the DOWNIE bit.

To activate the Encoder mode the ENC bit has to be set to '1'. The LPTIM must first be configured in Continuous mode.

When Encoder mode is active, the LPTIM counter is modified automatically following the speed and the direction of the incremental encoder. Therefore, its content always represents the encoder's position. The count direction, signaled by the Up and Down flags, correspond to the rotation direction of the encoder rotor.

According to the edge sensitivity configured using the CKPOL[1:0] bits, different counting scenarios are possible. The following table summarizes the possible combinations, assuming that Input1 and Input2 do not switch at the same time.

Table 216. Encoder counting scenarios

| Active edge  | Level on opposite signal (Input1 for Input2, Input2 for Input1) | Input1 signal |          | Input2 signal |          |
|--------------|-----------------------------------------------------------------|---------------|----------|---------------|----------|
|              |                                                                 | Rising        | Falling  | Rising        | Falling  |
| Rising Edge  | High                                                            | Down          | No count | Up            | No count |
|              | Low                                                             | Up            | No count | Down          | No count |
| Falling Edge | High                                                            | No count      | Up       | No count      | Down     |
|              | Low                                                             | No count      | Down     | No count      | Up       |
| Both Edges   | High                                                            | Down          | Up       | Up            | Down     |
|              | Low                                                             | Up            | Down     | Down          | Up       |

The following figure shows a counting sequence for Encoder mode where both-edge sensitivity is configured.

**Caution:** In this mode the LPTIM must be clocked by an internal clock source, so the CKSEL bit must be maintained to its reset value which is equal to '0'. Also, the prescaler division ratio must be equal to its reset value which is 1 (PRESC[2:0] bits must be '000').

Figure 384. Encoder mode counting sequence

#### 34.4.14 Debug mode

When the microcontroller enters debug mode (core halted), the LPTIM counter either continues to work normally or stops, depending on the DBG\_LPTIM\_STOP configuration bit in the DBG module.

## 34.5 LPTIM low-power modes

**Table 217. Effect of low-power modes on the LPTIM**

| Mode            | Description                                                                                                                                                                                       |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Sleep           | No effect. LPTIM interrupts cause the device to exit Sleep mode.                                                                                                                                  |
| Low-power run   | No effect.                                                                                                                                                                                        |
| Low-power sleep | No effect. LPTIM interrupts cause the device to exit the Low-power sleep mode.                                                                                                                    |
| Stop 0 / Stop 1 | No effect when LPTIM is clocked by LSE or LSI. LPTIM interrupts cause the device to exit Stop 0 and Stop 1.                                                                                       |
| Stop 2          | No effect on LPTIM1 when LPTIM1 is clocked by LSE or LSI. LPTIM1 interrupts cause the device to exit Stop 2. LPTIM2 registers content is kept but LPTIM2 must be disabled before entering Stop 2. |
| Standby         | The LPTIM peripheral is powered down and must be reinitialized after exiting Standby or Shutdown mode.                                                                                            |
| Shutdown        |                                                                                                                                                                                                   |

## 34.6 LPTIM interrupts

The following events generate an interrupt/wake-up event, if they are enabled through the LPTIM\_IER register:

- Compare match
- Auto-reload match (whatever the direction if encoder mode)
- External trigger event
- Autoreload register write completed
- Compare register write completed
- Direction change (encoder mode), programmable (up / down / both).

*Note: If any bit in the LPTIM\_IER register (Interrupt Enable Register) is set after that its corresponding flag in the LPTIM\_ISR register (Status Register) is set, the interrupt is not asserted.*

**Table 218. Interrupt events**

| Interrupt event                | Description                                                                                                                                |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| Compare match                  | Interrupt flag is raised when the content of the Counter register (LPTIM_CNT) matches the content of the compare register (LPTIM_CMP).     |
| Auto-reload match              | Interrupt flag is raised when the content of the Counter register (LPTIM_CNT) matches the content of the Auto-reload register (LPTIM_ARR). |
| External trigger event         | Interrupt flag is raised when an external trigger event is detected                                                                        |
| Auto-reload register update OK | Interrupt flag is raised when the write operation to the LPTIM_ARR register is complete.                                                   |

Table 218. Interrupt events (continued)

| Interrupt event            | Description                                                                                                                                                                                                                                      |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Compare register update OK | Interrupt flag is raised when the write operation to the LPTIM_CMP register is complete.                                                                                                                                                         |
| Direction change           | Used in Encoder mode. Two interrupt flags are embedded to signal direction change: <ul style="list-style-type: none"> <li>– UP flag signals up-counting direction change</li> <li>– DOWN flag signals down-counting direction change.</li> </ul> |

## 34.7 LPTIM registers

Refer to [Section 1.2: List of abbreviations for registers](#) for a list of abbreviations used in register descriptions.

The peripheral registers can only be accessed by words (32-bit).

### 34.7.1 LPTIM interrupt and status register (LPTIM\_ISR)

Address offset: 0x000

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |      |      |        |        |          |      |      |
|------|------|------|------|------|------|------|------|------|------|------|--------|--------|----------|------|------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20     | 19     | 18       | 17   | 16   |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.   | Res.   | Res.     | Res. | Res. |
|      |      |      |      |      |      |      |      |      |      |      |        |        |          |      |      |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4      | 3      | 2        | 1    | 0    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | DOWN | UP   | ARR OK | CMP OK | EXT TRIG | ARRM | CMPM |
|      |      |      |      |      |      |      |      |      | r    | r    | r      | r      | r        | r    | r    |

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **DOWN**: Counter direction change up to down

In Encoder mode, DOWN bit is set by hardware to inform application that the counter direction has changed from up to down. DOWN flag can be cleared by writing 1 to the DOWNCF bit in the LPTIM\_ICR register.

*Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Please refer to [Section 34.3: LPTIM implementation](#).*

Bit 5 **UP**: Counter direction change down to up

In Encoder mode, UP bit is set by hardware to inform application that the counter direction has changed from down to up. UP flag can be cleared by writing 1 to the UPCF bit in the LPTIM\_ICR register.

*Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Please refer to [Section 34.3: LPTIM implementation](#).*

Bit 4 **ARROK**: Autoreload register update OK

ARROK is set by hardware to inform application that the APB bus write operation to the LPTIM\_ARR register has been successfully completed. ARROK flag can be cleared by writing 1 to the ARROKCF bit in the LPTIM\_ICR register.

Bit 3 **CMPOK**: Compare register update OK

CMPOK is set by hardware to inform application that the APB bus write operation to the LPTIM\_CMP register has been successfully completed. CMPOK flag can be cleared by writing 1 to the CMPOKCF bit in the LPTIM\_ICR register.

Bit 2 **EXTTRIG**: External trigger edge event

EXTTRIG is set by hardware to inform application that a valid edge on the selected external trigger input has occurred. If the trigger is ignored because the timer has already started, then this flag is not set. EXTTRIG flag can be cleared by writing 1 to the EXTTRIGCF bit in the LPTIM\_ICR register.

Bit 1 **ARRM**: Autoreload match

ARRM is set by hardware to inform application that LPTIM\_CNT register's value reached the LPTIM\_ARR register's value. ARRM flag can be cleared by writing 1 to the ARRMCF bit in the LPTIM\_ICR register.

Bit 0 **CMPM**: Compare match

The CMPM bit is set by hardware to inform application that LPTIM\_CNT register value reached the LPTIM\_CMP register's value. CMPM flag can be cleared by writing 1 to the CMPMCF bit in the LPTIM\_ICR register.

### 34.7.2 LPTIM interrupt clear register (LPTIM\_ICR)

Address offset: 0x004

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |            |      |             |             |               |            |            |
|------|------|------|------|------|------|------|------|------|------------|------|-------------|-------------|---------------|------------|------------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22         | 21   | 20          | 19          | 18            | 17         | 16         |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.       | Res. | Res.        | Res.        | Res.          | Res.       | Res.       |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6          | 5    | 4           | 3           | 2             | 1          | 0          |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | DOWN<br>CF | UPCF | ARRO<br>KCF | CMPO<br>KCF | EXTTR<br>IGCF | ARRM<br>CF | CMPM<br>CF |
|      |      |      |      |      |      |      |      |      | w          | w    | w           | w           | w             | w          | w          |

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **DOWNCF**: Direction change to down clear flag

Writing 1 to this bit clear the DOWN flag in the LPTIM\_ISR register.

*Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Please refer to [Section 34.3: LPTIM implementation](#).*

Bit 5 **UPCF**: Direction change to UP clear flag

Writing 1 to this bit clear the UP flag in the LPTIM\_ISR register.

*Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Please refer to [Section 34.3: LPTIM implementation](#).*

Bit 4 **ARROKCF**: Autoreload register update OK clear flag

Writing 1 to this bit clears the ARROK flag in the LPTIM\_ISR register

Bit 3 **CMPOKCF**: Compare register update OK clear flag

Writing 1 to this bit clears the CMPOK flag in the LPTIM\_ISR register

Bit 2 **EXTTRIGCF**: External trigger valid edge clear flag

Writing 1 to this bit clears the EXTTRIG flag in the LPTIM\_ISR register

Bit 1 **ARRMCF**: Autoreload match clear flag

Writing 1 to this bit clears the ARRM flag in the LPTIM\_ISR register

Bit 0 **CMPMCF**: Compare match clear flag

Writing 1 to this bit clears the CMPM flag in the LPTIM\_ISR register

### 34.7.3 LPTIM interrupt enable register (LPTIM\_IER)

Address offset: 0x008

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |            |      |             |             |               |            |            |
|------|------|------|------|------|------|------|------|------|------------|------|-------------|-------------|---------------|------------|------------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22         | 21   | 20          | 19          | 18            | 17         | 16         |

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **DOWNIE**: Direction change to down Interrupt Enable

0: DOWN interrupt disabled

1: DOWN interrupt enabled

*Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Please refer to [Section 34.3: LPTIM implementation](#).*

Bit 5 **UPIE**: Direction change to UP Interrupt Enable

0: UP interrupt disabled

1: UP interrupt enabled

*Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Please refer to [Section 34.3: LPTIM implementation](#).*

Bit 4 **ARROKIE**: Autoreload register update OK Interrupt Enable

0: ARROK interrupt disabled

1: ARROK interrupt enabled

Bit 3 **CMPOKIE**: Compare register update OK Interrupt Enable

0: CMPOK interrupt disabled

1: CMPOK interrupt enabled

Bit 2 **EXTTRIGIE**: External trigger valid edge Interrupt Enable

0: EXTTRIG interrupt disabled

1: EXTTRIG interrupt enabled

Bit 1 **ARRMIE**: Autoreload match Interrupt Enable

0: ARRM interrupt disabled

1: ARRM interrupt enabled

Bit 0 **CMPMIE**: Compare match Interrupt Enable

0: CMPM interrupt disabled

1: CMPM interrupt enabled

**Caution:** The LPTIM\_IER register must only be modified when the LPTIM is disabled (ENABLE bit reset to '0')

### 34.7.4 LPTIM configuration register (LPTIM\_CFGR)

Address offset: 0x00C

Reset value: 0x0000 0000

|              |      |      |      |            |      |      |      |               |         |        |            |        |             |    |       |

| rw           | rw   | rw   |      | rw         | rw   | rw   |      | rw            | rw      |        | rw         | rw     | rw          | rw | rw    |

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 Reserved, must be kept at reset value.

Bits 28:25 Reserved, must be kept at reset value.

Bit 24 **ENC**: Encoder mode enable

The ENC bit controls the Encoder mode

0: Encoder mode disabled

1: Encoder mode enabled

*Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Please refer to [Section 34.3: LPTIM implementation](#).*

Bit 23 **COUNTMODE**: counter mode enabled

The COUNTMODE bit selects which clock source is used by the LPTIM to clock the counter:

0: the counter is incremented following each internal clock pulse

1: the counter is incremented following each valid clock pulse on the LPTIM external Input1

Bit 22 **PRELOAD**: Registers update mode

The PRELOAD bit controls the LPTIM\_ARR and the LPTIM\_CMP registers update modality

0: Registers are updated after each APB bus write access

1: Registers are updated at the end of the current LPTIM period

Bit 21 **WAVPOL**: Waveform shape polarity

The WAVEPOL bit controls the output polarity

0: The LPTIM output reflects the compare results between LPTIM\_CNT and LPTIM\_CMP registers

1: The LPTIM output reflects the inverse of the compare results between LPTIM\_CNT and LPTIM\_CMP registers

Bit 20 **WAVE**: Waveform shape

The WAVE bit controls the output shape

0: Deactivate Set-once mode

1: Activate the Set-once mode

Bit 19 **TIMOUT**: Timeout enable

The TIMOUT bit controls the Timeout feature

0: A trigger event arriving when the timer is already started will be ignored

1: A trigger event arriving when the timer is already started will reset and restart the counter

Bits 18:17 **TRIGEN[1:0]**: Trigger enable and polarity

The TRIGEN bits controls whether the LPTIM counter is started by an external trigger or not. If the external trigger option is selected, three configurations are possible for the trigger active edge:

00: software trigger (counting start is initiated by software)

01: rising edge is the active edge

10: falling edge is the active edge

11: both edges are active edges

Bit 16 Reserved, must be kept at reset value.

Bits 15:13 **TRIGSEL[2:0]**: Trigger selector

The TRIGSEL bits select the trigger source that will serve as a trigger event for the LPTIM among the below 8 available sources:

000: lptim\_ext\_trig0

001: lptim\_ext\_trig1

010: lptim\_ext\_trig2

011: lptim\_ext\_trig3

100: lptim\_ext\_trig4

101: lptim\_ext\_trig5

110: lptim\_ext\_trig6

111: lptim\_ext\_trig7

See [Section 34.4.2: LPTIM trigger mapping](#) for details.

Bit 12 Reserved, must be kept at reset value.

Bits 11:9 **PRESC[2:0]**: Clock prescaler

The PRESC bits configure the prescaler division factor. It can be one among the following division factors:

000: /1

001: /2

010: /4

011: /8

100: /16

101: /32

110: /64

111: /128

Bit 8 Reserved, must be kept at reset value.

Bits 7:6 **TRGFLT[1:0]**: Configurable digital filter for trigger

The TRGFLT value sets the number of consecutive equal samples that should be detected when a level change occurs on an internal trigger before it is considered as a valid level transition. An internal clock source must be present to use this feature

00: any trigger active level change is considered as a valid trigger

01: trigger active level change must be stable for at least 2 clock periods before it is considered as valid trigger.

10: trigger active level change must be stable for at least 4 clock periods before it is considered as valid trigger.

11: trigger active level change must be stable for at least 8 clock periods before it is considered as valid trigger.

Bit 5 Reserved, must be kept at reset value.

Bits 4:3 **CKFLT[1:0]**: Configurable digital filter for external clock

The CKFLT value sets the number of consecutive equal samples that should be detected when a level change occurs on an external clock signal before it is considered as a valid level transition. An internal clock source must be present to use this feature

00: any external clock signal level change is considered as a valid transition

01: external clock signal level change must be stable for at least 2 clock periods before it is considered as valid transition.

10: external clock signal level change must be stable for at least 4 clock periods before it is considered as valid transition.

11: external clock signal level change must be stable for at least 8 clock periods before it is considered as valid transition.

Bits 2:1 **CKPOL[1:0]**: Clock polarity

If LPTIM is clocked by an external clock source:

When the LPTIM is clocked by an external clock source, CKPOL bits is used to configure the active edge or edges used by the counter:

00: the rising edge is the active edge used for counting.

If the LPTIM is configured in Encoder mode (ENC bit is set), the encoder sub-mode 1 is active.

01: the falling edge is the active edge used for counting

If the LPTIM is configured in Encoder mode (ENC bit is set), the encoder sub-mode 2 is active.

10: both edges are active edges. When both external clock signal edges are considered active ones, the LPTIM must also be clocked by an internal clock source with a frequency equal to at least four times the external clock frequency.

If the LPTIM is configured in Encoder mode (ENC bit is set), the encoder sub-mode 3 is active.

11: not allowed

Refer to [Section 34.4.13: Encoder mode](#) for more details about Encoder mode sub-modes.

Bit 0 **CKSEL**: Clock selector

The CKSEL bit selects which clock source the LPTIM will use:

0: LPTIM is clocked by internal clock source (APB clock or any of the embedded oscillators)

1: LPTIM is clocked by an external clock source through the LPTIM external Input1

**Caution:** The LPTIM\_CFGR register must only be modified when the LPTIM is disabled (ENABLE bit reset to '0').

### 34.7.5 LPTIM control register (LPTIM\_CR)

Address offset: 0x010

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |      |      |      |      |             |             |            |
|------|------|------|------|------|------|------|------|------|------|------|------|------|-------------|-------------|------------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18          | 17          | 16         |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.        | Res.        | Res.       |
|      |      |      |      |      |      |      |      |      |      |      |      |      |             |             |            |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2           | 1           | 0          |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | CNT<br>STRT | SNG<br>STRT | ENA<br>BLE |
|      |      |      |      |      |      |      |      |      |      |      |      |      | rw          | rw          | rw         |

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **CNTSTRT**: Timer start in Continuous mode

This bit is set by software and cleared by hardware.

In case of software start (TRIGEN[1:0] = '00'), setting this bit starts the LPTIM in Continuous mode.

If the software start is disabled (TRIGEN[1:0] different than '00'), setting this bit starts the timer in Continuous mode as soon as an external trigger is detected.

If this bit is set when a single pulse mode counting is ongoing, then the timer will not stop at the next match between the LPTIM\_ARR and LPTIM\_CNT registers and the LPTIM counter keeps counting in Continuous mode.

This bit can be set only when the LPTIM is enabled. It will be automatically reset by hardware.

Bit 1 **SNGSTRT**: LPTIM start in Single mode

This bit is set by software and cleared by hardware.

In case of software start (TRIGEN[1:0] = '00'), setting this bit starts the LPTIM in single pulse mode.

If the software start is disabled (TRIGEN[1:0] different than '00'), setting this bit starts the LPTIM in single pulse mode as soon as an external trigger is detected.

If this bit is set when the LPTIM is in continuous counting mode, then the LPTIM will stop at the following match between LPTIM\_ARR and LPTIM\_CNT registers.

This bit can only be set when the LPTIM is enabled. It will be automatically reset by hardware.

Bit 0 **ENABLE**: LPTIM enable

The ENABLE bit is set and cleared by software.

0:LPTIM is disabled

1:LPTIM is enabled

### 34.7.6 LPTIM compare register (LPTIM\_CMP)

Address offset: 0x014

Reset value: 0x0000 0000

|           |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|-----------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| 31        | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |

|           |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| 15        | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| CMP[15:0] |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| rw        | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **CMP[15:0]**: Compare value

CMP is the compare value used by the LPTIM.

**Caution:** The LPTIM\_CMP register must only be modified when the LPTIM is enabled (ENABLE bit set to '1').

### 34.7.7 LPTIM autoreload register (LPTIM\_ARR)

Address offset: 0x018

Reset value: 0x0000 0001

|           |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|-----------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| 31        | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Res.      | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. |
|           |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| 15        | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| ARR[15:0] |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| rW        | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **ARR[15:0]**: Auto reload value

ARR is the autoreload value for the LPTIM.

This value must be strictly greater than the CMP[15:0] value.

**Caution:** The LPTIM\_ARR register must only be modified when the LPTIM is enabled (ENABLE bit set to '1').

### 34.7.8 LPTIM counter register (LPTIM\_CNT)

Address offset: 0x01C

Reset value: 0x0000 0000

|           |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|-----------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| 31        | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Res.      | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. |
|           |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| 15        | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| CNT[15:0] |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| r         | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **CNT[15:0]**: Counter value

When the LPTIM is running with an asynchronous clock, reading the LPTIM\_CNT register may return unreliable values. So in this case it is necessary to perform two consecutive read accesses and verify that the two returned values are identical.

It should be noted that for a reliable LPTIM\_CNT register read access, two consecutive read accesses must be performed and compared. A read access can be considered reliable when the values of the two consecutive read accesses are equal.

### 34.7.9 LPTIM1 option register (LPTIM1\_OR)

Address offset: 0x020

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. |
|      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | OR_1 | OR_0 |
|      |      |      |      |      |      |      |      |      |      |      |      |      |      | rw   | rw   |

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **OR\_1**: Option register bit 1

- 0: LPTIM1 input 2 is connected to I/O
- 1: LPTIM1 input 2 is connected to COMP2\_OUT

Bit 0 **OR\_0**: Option register bit 0

- 0: LPTIM1 input 1 is connected to I/O
- 1: LPTIM1 input 1 is connected to COMP1\_OUT

### 34.7.10 LPTIM2 option register (LPTIM2\_OR)

Address offset: 0x020

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|

1. If LPTIM does not support encoder mode feature, this bit is reserved. Please refer to [Section 34.3: LPTIM implementation](#).

Refer to [Section 2.2 on page 75](#) for the register boundary addresses.

## 35 Infrared interface (IRTIM)

An infrared interface (IRTIM) for remote control is available on the device. It can be used with an infrared LED to perform remote control functions.

It uses internal connections with TIM16, and TIM17 as shown in [Figure 385](#).

To generate the infrared remote control signals, the IR interface must be enabled and TIM16 channel 1 (TIM16\_OC1) and TIM17 channel 1 (TIM17\_OC1) must be properly configured to generate correct waveforms.

The infrared receiver can be implemented easily through a basic input capture mode.

**Figure 385. IRTIM internal hardware connections with TIM16 and TIM17**

All standard IR pulse modulation modes can be obtained by programming the two timer output compare channels.

TIM17 is used to generate the high frequency carrier signal, while TIM16 generates the modulation envelope.

The infrared function is output on the IR\_OUT pin. The activation of this function is done through the GPIOx\_AFRx register by enabling the related alternate function bit.

The high sink LED driver capability (only available on the PB9 pin) can be activated through the I2C\_PB9\_FMP bit in the SYSCFG\_CFGR1 register and used to sink the high current needed to directly control an infrared LED.

## 36 Independent watchdog (IWDG)

### 36.1 Introduction

The devices feature an embedded watchdog peripheral (IWDG) that offers a combination of high safety level, timing accuracy, and flexibility of use. This peripheral detects and solves malfunctions due to software failure, and triggers a system reset when the counter reaches a given timeout value.

The independent watchdog is clocked by its own dedicated low-speed clock (LSI), and stays active even if the main clock fails.

The IWDG is best suited for applications that require the watchdog to run as a totally independent process outside the main application, but have lower timing accuracy constraints. For further information on the window watchdog, refer to [Section 37: System window watchdog \(WWDG\)](#).

### 36.2 IWDG main features

- Free-running downcounter
- Clocked from an independent RC oscillator (can operate in Standby and Stop modes)
- Conditional reset
  - Reset (if watchdog is activated) when the downcounter value becomes lower than 0x000
  - Reset (if watchdog is activated) if the downcounter is reloaded outside the window

### 36.3 IWDG functional description

#### 36.3.1 IWDG block diagram

[Figure 386](#) shows the functional blocks of the independent watchdog module.

**Figure 386. Independent watchdog block diagram**

1. The register interface is located in the  $V_{CORE}$  voltage domain. The watchdog function is located in the  $V_{DD}$  voltage domain, still functional in Stop and Standby modes.

When the independent watchdog is started by writing the value 0x0000 CCCC in the *IWDG key register (IWDG\_KR)*, the counter starts counting down from the reset value of 0xFFFF. When it reaches the end of count value (0x000), a reset signal is generated (IWDG reset).

Whenever the key value 0x0000 AAAA is written in the *IWDG key register (IWDG\_KR)*, the IWDG\_RLR value is reloaded in the counter, and the watchdog reset is prevented.

Once running, the IWDG cannot be stopped.

### 36.3.2 Window option

The IWDG can also work as a window watchdog by setting the appropriate window in the *IWDG window register (IWDG\_WINR)*.

If the reload operation is performed while the counter is greater than the value stored in the *IWDG window register (IWDG\_WINR)*, a reset is provided.

The default value of the *IWDG window register (IWDG\_WINR)* is 0x0000 0FFF, so if it is not updated, the window option is disabled.

As soon as the window value is changed, a reload operation is performed to reset the downcounter to the *IWDG reload register (IWDG\_RLR)* value, and to ease the cycle number calculation to generate the next reload.

#### Configuring the IWDG when the window option is enabled

1. Enable the IWDG by writing 0x0000 CCCC in the *IWDG key register (IWDG\_KR)*.
2. Enable register access by writing 0x0000 5555 in the *IWDG key register (IWDG\_KR)*.
3. Write the IWDG prescaler by programming *IWDG prescaler register (IWDG\_PR)* from 0 to 7.
4. Write the *IWDG reload register (IWDG\_RLR)*.
5. Wait for the registers to be updated (IWDG\_SR = 0x0000 0000).
6. Write to the *IWDG window register (IWDG\_WINR)*. This automatically refreshes the counter value in the *IWDG reload register (IWDG\_RLR)*.

*Note:* Writing the window value allows the counter value to be refreshed by the RLR when the *IWDG status register (IWDG\_SR)* is set to 0x0000 0000.

#### Configuring the IWDG when the window option is disabled

When the window option is not used, the IWDG can be configured as follows:

1. Enable the IWDG by writing 0x0000 CCCC in the *IWDG key register (IWDG\_KR)*.
2. Enable register access by writing 0x0000 5555 in the *IWDG key register (IWDG\_KR)*.
3. Write the prescaler by programming the *IWDG prescaler register (IWDG\_PR)* from 0 to 7.
4. Write the *IWDG reload register (IWDG\_RLR)*.
5. Wait for the registers to be updated (IWDG\_SR = 0x0000 0000).
6. Refresh the counter value with IWDG\_RLR (IWDG\_KR = 0x0000 AAAA).

### 36.3.3 Hardware watchdog

If this feature is enabled through the device option bits, the watchdog is automatically enabled at power-on, and generates a reset unless the *IWDG key register (IWDG\_KR)* is written by the software before the counter reaches the end of count, or if the downcounter is reloaded inside the window.

### 36.3.4 Low-power freeze

Depending on the IWDG\_STOP and IWDG\_STBY options configuration, the IWDG can continue counting or not during the Stop mode and the Standby mode, respectively. If the IWDG is kept running during Stop or Standby modes, it can wake up the device from this mode. Refer to [Section : User and read protection option bytes](#) for more details.

### 36.3.5 Register access protection

Write access to *IWDG prescaler register (IWDG\_PR)*, *IWDG reload register (IWDG\_RLR)*, and *IWDG window register (IWDG\_WINR)* is protected. To modify it, first write the code 0x0000 5555 in the *IWDG key register (IWDG\_KR)*. A write access to this register with a different value breaks the sequence, and register access is protected again. This is the case of the reload operation (writing 0x0000 AAAA).

A status register is available to indicate that an ongoing update of the prescaler, or of the downcounter reload value, or of the window value.

### 36.3.6 Debug mode

When the device enters Debug mode (core halted), the IWDG counter either continues to work normally or stops, depending on the configuration of the corresponding bit in DBGMCU freeze register.

## 36.4 IWDG registers

Refer to [Section 1.2 on page 69](#) for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

### 36.4.1 IWDG key register (IWDG\_KR)

Address offset: 0x00

Reset value: 0x0000 0000 (reset by Standby mode)

|           |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|-----------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| 31        | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Res.      | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. |
|           |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| 15        | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| KEY[15:0] |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| w         | w    | w    | w    | w    | w    | w    | w    | w    | w    | w    | w    | w    | w    | w    | w    |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **KEY[15:0]**: Key value (write only, read 0x0000)

These bits must be written by software at regular intervals with the key value 0xAAAA, otherwise the watchdog generates a reset when the counter reaches 0.

Writing the key value 0x5555 to enable access to the IWDG\_PR, IWDG\_RLR and IWDG\_WINR registers (see [Section 36.3.5: Register access protection](#))

Writing the key value 0xCCCC starts the watchdog (except if the hardware watchdog option is selected)

### 36.4.2 IWDG prescaler register (IWDG\_PR)

Address offset: 0x04

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |      |      |      |      |         |      |      |
|------|------|------|------|------|------|------|------|------|------|------|------|------|---------|------|------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18      | 17   | 16   |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.    | Res. | Res. |
|      |      |      |      |      |      |      |      |      |      |      |      |      |         |      |      |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2       | 1    | 0    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | PR[2:0] |      |      |
|      |      |      |      |      |      |      |      |      |      |      |      |      | rw      | rw   | rw   |

Bits 31:3 Reserved, must be kept at reset value.

Bits 2:0 **PR[2:0]**: Prescaler divider

These bits are write access protected see [Section 36.3.5: Register access protection](#). They are written by software to select the prescaler divider feeding the counter clock. PVU bit of the [IWDG status register \(IWDG\\_SR\)](#) must be reset in order to be able to change the prescaler divider.

000: divider /4

001: divider /8

010: divider /16

011: divider /32

100: divider /64

101: divider /128

110: divider /256

111: divider /256

*Note:* Reading this register returns the prescaler value from the  $V_{DD}$  voltage domain. This value may not be up to date/valid if a write operation to this register is ongoing. For this reason the value read from this register is valid only when the PVU bit in the [IWDG status register \(IWDG\\_SR\)](#) is reset.

### 36.4.3 IWDG reload register (IWDG\_RLR)

Address offset: 0x08

Reset value: 0x0000 0FFF (reset by Standby mode)

|      |      |      |      |          |      |      |      |      |      |      |      |      |      |      |      |
|------|------|------|------|----------|------|------|------|------|------|------|------|------|------|------|------|
| 31   | 30   | 29   | 28   | 27       | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Res. | Res. | Res. | Res. | Res.     | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. |
|      |      |      |      |          |      |      |      |      |      |      |      |      |      |      |      |
| 15   | 14   | 13   | 12   | 11       | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| Res. | Res. | Res. | Res. | RL[11:0] |      |      |      |      |      |      |      |      |      |      |      |
|      |      |      |      | r/w      | r/w  | r/w  | r/w  | r/w  | r/w  | r/w  | r/w  | r/w  | r/w  | r/w  | r/w  |

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 **RL[11:0]**: Watchdog counter reload value

These bits are write access protected see [Register access protection](#). They are written by software to define the value to be loaded in the watchdog counter each time the value 0xAAAA is written in the [IWDG key register \(IWDG\\_KR\)](#). The watchdog counter counts down from this value. The timeout period is a function of this value and the clock prescaler. Refer to the datasheet for the timeout information.

The RVU bit in the [IWDG status register \(IWDG\\_SR\)](#) must be reset to be able to change the reload value.

*Note: Reading this register returns the reload value from the  $V_{DD}$  voltage domain. This value may not be up to date/valid if a write operation to this register is ongoing on it. For this reason the value read from this register is valid only when the RVU bit in the [IWDG status register \(IWDG\\_SR\)](#) is reset.*

### 36.4.4 IWDG status register (IWDG\_SR)

Address offset: 0x0C

Reset value: 0x0000 0000 (not reset by Standby mode)

|      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. |
|      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | WVU  | RVU  | PVU  |
|      |      |      |      |      |      |      |      |      |      |      |      |      | r    | r    | r    |

Bits 31:3 Reserved, must be kept at reset value.

**Bit 2 WVU:** Watchdog counter window value update

This bit is set by hardware to indicate that an update of the window value is ongoing. It is reset by hardware when the reload value update operation is completed in the  $V_{DD}$  voltage domain (takes up to five LSI/prescaled clock cycles).

Window value can be updated only when WVU bit is reset.

**Bit 1 RVU:** Watchdog counter reload value update

This bit is set by hardware to indicate that an update of the reload value is ongoing. It is reset by hardware when the reload value update operation is completed in the  $V_{DD}$  voltage domain (takes up to five LSI/prescaled clock cycles).

Reload value can be updated only when RVU bit is reset.

**Bit 0 PVU:** Watchdog prescaler value update

This bit is set by hardware to indicate that an update of the prescaler value is ongoing. It is reset by hardware when the prescaler update operation is completed in the  $V_{DD}$  voltage domain (takes up to five LSI/prescaled clock cycles).

Prescaler value can be updated only when PVU bit is reset.

**Note:** *If several reload, prescaler, or window values are used by the application, it is mandatory to wait until RVU bit is reset before changing the reload value, to wait until PVU bit is reset before changing the prescaler value, and to wait until WVU bit is reset before changing the window value. However, after updating the prescaler and/or the reload/window value it is not necessary to wait until RVU or PVU or WVU is reset before continuing code execution except in case of low-power mode entry.*

### 36.4.5 IWDG window register (IWDG\_WINR)

Address offset: 0x10

Reset value: 0x0000 0FFF (reset by Standby mode)

|      |      |      |      |           |      |      |      |      |      |      |      |      |      |      |      |
|------|------|------|------|-----------|------|------|------|------|------|------|------|------|------|------|------|
| 31   | 30   | 29   | 28   | 27        | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Res. | Res. | Res. | Res. | Res.      | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. |
|      |      |      |      |           |      |      |      |      |      |      |      |      |      |      |      |
| 15   | 14   | 13   | 12   | 11        | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| Res. | Res. | Res. | Res. | WIN[11:0] |      |      |      |      |      |      |      |      |      |      |      |
|      |      |      |      | rw        | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   |

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 **WIN[11:0]**: Watchdog counter window value

These bits are write access protected, see [Section 36.3.5](#), they contain the high limit of the window value to be compared with the downcounter.

To prevent a reset, the downcounter must be reloaded when its value is lower than the window register value and greater than 0x0

The WVU bit in the [IWDG status register \(IWDG\\_SR\)](#) must be reset in order to be able to change the reload value.

*Note: Reading this register returns the reload value from the  $V_{DD}$  voltage domain. This value may not be valid if a write operation to this register is ongoing. For this reason the value read from this register is valid only when the WVU bit in the [IWDG status register \(IWDG\\_SR\)](#) is reset.*

### 36.4.6 IWDG register map

The following table gives the IWDG register map and reset values.

**Table 220. IWDG register map and reset values**

| Offset | Register name | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15        | 14 | 13 | 12 | 11 | 10        | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1       | 0   |     |     |
|--------|---------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-----------|----|----|----|----|-----------|---|---|---|---|---|---|---|---|---------|-----|-----|-----|
| 0x00   | IWDG_KR       |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | KEY[15:0] |    |    |    |    |           |   |   |   |   |   |   |   |   |         |     |     |     |
|        | Reset value   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | 0         | 0  | 0  | 0  | 0  | 0         | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0       |     |     |     |

|        | Reset value   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |           |    |    |    |    |           |   |   |   |   |   |   |   | 0 | 0       | 0   |     |     |
| 0x08   | IWDG_RLR      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |           |    |    |    |    | RL[11:0]  |   |   |   |   |   |   |   |   |         |     |     |     |
|        | Reset value   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |           |    |    |    | 1  | 1         | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1       | 1   |     |     |
| 0x0C   | IWDG_SR       |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |           |    |    |    |    |           |   |   |   |   |   |   |   |   |         | WVU | RVU | PVU |
|        | Reset value   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |           |    |    |    |    |           |   |   |   |   |   |   |   | 0 | 0       | 0   |     |     |
| 0x10   | IWDG_WINR     |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |           |    |    |    |    | WIN[11:0] |   |   |   |   |   |   |   |   |         |     |     |     |
|        | Reset value   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |           |    |    |    | 1  | 1         | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1       | 1   |     |     |

Refer to [Section 2.2 on page 75](#) for the register boundary addresses.

## 37 System window watchdog (WWDG)

### 37.1 Introduction

The system window watchdog (WWDG) is used to detect the occurrence of a software fault, usually generated by external interference or by unforeseen logical conditions, which causes the application program to abandon its normal sequence.

The watchdog circuit generates an MCU reset on expiry of a programmed time period, unless the program refreshes the contents of the down-counter before the T6 bit is cleared. An MCU reset is also generated if the 7-bit down-counter value (in the control register) is refreshed before the down-counter reaches the window register value. This implies that the counter must be refreshed in a limited window.

The WWDG clock is prescaled from the APB clock and has a configurable time-window that can be programmed to detect abnormally late or early application behavior.

The WWDG is best suited for applications requiring the watchdog to react within an accurate timing window.

### 37.2 WWDG main features

- Programmable free-running down-counter
- Conditional reset
  - Reset (if watchdog activated) when the down-counter value becomes lower than 0x40
  - Reset (if watchdog activated) if the down-counter is reloaded outside the window (see [Figure 388](#))
- Early wake-up interrupt (EWI): triggered (if enabled and the watchdog activated) when the down-counter is equal to 0x40

### 37.3 WWDG functional description

If the watchdog is activated (the WDGA bit is set in the WWDG\_CR register), and when the 7-bit down-counter (T[6:0] bits) is decremented from 0x40 to 0x3F (T6 becomes cleared), it initiates a reset. If the software reloads the counter while the counter is greater than the value stored in the window register, then a reset is generated.

The application program must write in the WWDG\_CR register at regular intervals during normal operation to prevent an MCU reset. This operation can take place only when the counter value is lower than or equal to the window register value, and higher than 0x3F. The value to be stored in the WWDG\_CR register must be between 0xFF and 0xC0.

Refer to [Figure 387](#) for the WWDG block diagram.

### 37.3.1 WWDG block diagram

Figure 387. Watchdog block diagram

### 37.3.2 Enabling the watchdog

The watchdog is always disabled after a reset. It is enabled by setting the WDGA bit in the WWDG\_CR register, then it cannot be disabled again except by a reset.

### 37.3.3 Controlling the down-counter

This down-counter is free-running, counting down even if the watchdog is disabled. When the watchdog is enabled, the T6 bit must be set to prevent generating an immediate reset.

The T[5:0] bits contain the number of increments that represent the time delay before the watchdog produces a reset. The timing varies between a minimum and a maximum value, due to the unknown status of the prescaler when writing to the WWDG\_CR register (see [Figure 388](#)). The *WWDG configuration register (WWDG\_CFR)* contains the high limit of the window: to prevent a reset, the down-counter must be reloaded when its value is lower than or equal to the window register value, and greater than 0x3F. [Figure 388](#) describes the window watchdog process.

*Note:* The T6 bit can be used to generate a software reset (the WDGA bit is set and the T6 bit is cleared).

### 37.3.4 How to program the watchdog timeout

Use the formula in [Figure 388](#) to calculate the WWDG timeout.

---

**Warning:** When writing to the WWDG\_CR register, always write 1 in the T6 bit to avoid generating an immediate reset.

---

Figure 388. Window watchdog timing diagram

The formula to calculate the timeout value is given by:

$$t_{WWDG} = t_{PCLK} \times 4096 \times 2^{WDGTB[1:0]} \times (T[5:0] + 1) \quad (\text{ms})$$

where:

$t_{WWDG}$ : WWDG timeout

$t_{PCLK}$ : APB clock period measured in ms

4096: value corresponding to internal divider

As an example, if APB frequency is 48 MHz,  $WDGTB[1:0]$  is set to 3, and  $T[5:0]$  is set to 63:

$$t_{WWDG} = (1 / 48000) \times 4096 \times 2^3 \times (63 + 1) = 43.69 \text{ ms}$$

Refer to the datasheet for the minimum and maximum values of  $t_{WWDG}$ .

### 37.3.5 Debug mode

When the device enters debug mode (processor halted), the WWDG counter either continues to work normally or stops, depending on the configuration bit in DBG module. For

more details, refer to [Section 48.16.2: Debug support for timers, RTC, watchdog, bxCAN and I<sup>2</sup>C](#).

## 37.4 WWDG interrupts

The early wake-up interrupt (EWI) can be used if specific safety operations or data logging must be performed before the reset is generated. To enable the early wake-up interrupt, the application must:

- Write EWIF bit of WWDG\_SR register to 0, to clear unwanted pending interrupt
- Write EWI bit of WWDG\_CFR register to 1, to enable interrupt

When the down-counter reaches the value 0x40, a watchdog interrupt is generated, and the corresponding interrupt service routine (ISR) can be used to trigger specific actions (such as communications or data logging), before resetting the device.

In some applications, the EWI interrupt can be used to manage a software system check and/or system recovery/graceful degradation, without generating a WWDG reset. In this case the corresponding ISR must reload the WWDG counter to avoid the WWDG reset, then trigger the required actions.

The watchdog interrupt is cleared by writing '0' to the EWIF bit in the WWDG\_SR register.

*Note: When the watchdog interrupt cannot be served (for example due to a system lock in a higher priority task), the WWDG reset is eventually generated.*

## 37.5 WWDG registers

Refer to [Section 1.2 on page 69](#) for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by halfwords (16-bit) or words (32-bit).

### 37.5.1 WWDG control register (WWDG\_CR)

Address offset: 0x000

Reset value: 0x0000 007F

|      |      |      |      |      |      |      |      |      |        |      |      |      |      |      |      |
|------|------|------|------|------|------|------|------|------|--------|------|------|------|------|------|------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22     | 21   | 20   | 19   | 18   | 17   | 16   |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.   | Res. | Res. | Res. | Res. | Res. | Res. |
|      |      |      |      |      |      |      |      |      |        |      |      |      |      |      |      |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6      | 5    | 4    | 3    | 2    | 1    | 0    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | WDGA | T[6:0] |      |      |      |      |      |      |
|      |      |      |      |      |      |      |      | rs   | rw     | rw   | rw   | rw   | rw   | rw   | rw   |

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **WDGA**: Activation bit

This bit is set by software and only cleared by hardware after a reset. When WDGA = 1, the watchdog can generate a reset.

0: Watchdog disabled

1: Watchdog enabled

Bits 6:0 **T[6:0]**: 7-bit counter (MSB to LSB)

These bits contain the value of the watchdog counter, decremented every  $(4096 \times 2^{\text{WDGTB}[1:0]})$  PCLK cycles. A reset is produced when it is decremented from 0x40 to 0x3F (T6 becomes cleared).

### 37.5.2 WWDG configuration register (WWDG\_CFR)

Address offset: 0x004

Reset value: 0x0000 007F

|      |      |      |      |      |      |      |            |      |        |      |      |      |      |      |      |
|------|------|------|------|------|------|------|------------|------|--------|------|------|------|------|------|------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24         | 23   | 22     | 21   | 20   | 19   | 18   | 17   | 16   |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.       | Res. | Res.   | Res. | Res. | Res. | Res. | Res. | Res. |
|      |      |      |      |      |      |      |            |      |        |      |      |      |      |      |      |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8          | 7    | 6      | 5    | 4    | 3    | 2    | 1    | 0    |
| Res. | Res. | Res. | Res. | Res. | Res. | EWI  | WDGTB[1:0] |      | W[6:0] |      |      |      |      |      |      |
|      |      |      |      |      |      | rs   | rw         | rw   | rw     | rw   | rw   | rw   | rw   | rw   | rw   |

Bits 31:10 Reserved, must be kept at reset value.

Bit 9 **EWI**: Early wake-up interrupt enable

Set by software and cleared by hardware after a reset. When set, an interrupt occurs whenever the counter reaches the value 0x40.

Bits 8:7 **WDGTB[1:0]**: Timer base

The time base of the prescaler can be modified as follows:

- 00: CK counter clock (PCLK div 4096) div 1
- 01: CK counter clock (PCLK div 4096) div 2
- 10: CK counter clock (PCLK div 4096) div 4
- 11: CK counter clock (PCLK div 4096) div 8

Bits 6:0 **W[6:0]**: 7-bit window value

These bits contain the window value to be compared with the down-counter.

### 37.5.3 WWDG status register (WWDG\_SR)

Address offset: 0x008

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |       |
|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|-------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.  |
|      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |       |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0     |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | EWIF  |
|      |      |      |      |      |      |      |      |      |      |      |      |      |      |      | rc_w0 |

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **EWIF**: Early wake-up interrupt flag

This bit is set by hardware when the counter has reached the value 0x40. It must be cleared by software by writing 0. Writing 1 has no effect. This bit is also set if the interrupt is not enabled.

### 37.5.4 WWDG register map

The following table gives the WWDG register map and reset values.

**Table 221. WWDG register map and reset values**

| Offset | Register name | 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   | 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8      | 7      | 6      | 5    | 4    | 3    | 2    | 1    | 0    |  |  |  |  |

Refer to [Section 2.2 on page 75](#) for the register boundary addresses.

## 38 Real-time clock (RTC)

### 38.1 Introduction

The RTC provides an automatic wake-up to manage all low-power modes.

The real-time clock (RTC) is an independent BCD timer/counter. The RTC provides a time-of-day clock/calendar with programmable alarm interrupts.

The RTC includes also a periodic programmable wake-up flag with interrupt capability.

Two 32-bit registers contain the seconds, minutes, hours (12- or 24-hour format), day (day of week), date (day of month), month, and year, expressed in binary coded decimal format (BCD). The sub-seconds value is also available in binary format.

Compensations for 28-, 29- (leap year), 30-, and 31-day months are performed automatically. Daylight saving time compensation can also be performed.

Additional 32-bit registers contain the programmable alarm subseconds, seconds, minutes, hours, day, and date.

A digital calibration feature is available to compensate for any deviation in crystal oscillator accuracy.

After Backup domain reset, all RTC registers are protected against possible parasitic write accesses.

As long as the supply voltage remains in the operating range, the RTC never stops, regardless of the device status (Run mode, low-power mode or under reset).

## 38.2 RTC main features

The RTC unit main features are the following (see [Figure 389: RTC block diagram](#)):

- Calendar with subseconds, seconds, minutes, hours (12 or 24 format), day (day of week), date (day of month), month, and year.
- Daylight saving compensation programmable by software.
- Programmable alarm with interrupt function. The alarm can be triggered by any combination of the calendar fields.
- Automatic wake-up unit generating a periodic flag that triggers an automatic wake-up interrupt.
- Reference clock detection: a more precise second source clock (50 or 60 Hz) can be used to enhance the calendar precision.
- Accurate synchronization with an external clock using the subsecond shift feature.
- Digital calibration circuit (periodic counter correction): 0.95 ppm accuracy, obtained in a calibration window of several seconds
- Time-stamp function for event saving
- Tamper detection event with configurable filter and internal pull-up
- Maskable interrupts/events:
  - Alarm A
  - Alarm B
  - Wake-up interrupt
  - Time-stamp
  - Tamper detection
- 32 backup registers.

## 38.3 RTC functional description

### 38.3.1 RTC block diagram

Figure 389. RTC block diagram

The RTC includes:

- Two alarms
- Three tamper events from I/Os
  - Tamper detection erases the backup registers.
- One timestamp event from I/O
- Tamper event detection can generate a timestamp event
- Timestamp can be generated when a switch to  $V_{BAT}$  occurs
- 32 x 32-bit backup registers
  - The backup registers (RTC\_BKPxR) are implemented in the RTC domain that remains powered-on by VBAT when the VDD power is switched off.
- Output functions: RTC\_OUT which selects one of the following two outputs:
  - RTC\_CALIB: 512 Hz or 1Hz clock output (with an LSE frequency of 32.768 kHz). This output is enabled by setting the COE bit in the RTC\_CR register.
  - RTC\_ALARM: This output is enabled by configuring the OSEL[1:0] bits in the RTC\_CR register which select the Alarm A, Alarm B or Wakeup outputs.
- Input functions:
  - RTC\_TS: timestamp event
  - RTC\_TAMP1: tamper1 event detection
  - RTC\_TAMP2: tamper2 event detection
  - RTC\_TAMP3: tamper3 event detection
  - RTC\_REFIN: 50 or 60 Hz reference clock input

### 38.3.2 GPIOs controlled by the RTC

RTC\_OUT, RTC\_TS and RTC\_TAMP1 are mapped on the same pin (PC13). PC13 pin configuration is controlled by the RTC, whatever the PC13 GPIO configuration, except for the RTC\_ALARM output open-drain mode. In this particular case, the GPIO must be configured as input. The RTC functions mapped on PC13 are available in all low-power modes and in VBAT mode.

The output mechanism follows the priority order shown in [Table 222](#).

**Table 222. RTC pin PC13 configuration<sup>(1)</sup>**

| PC13 Pin configuration and function | OSEL[1:0] bits (RTC_ALARM output enable) | COE bit (RTC_CALIB output enable) | RTC_OUT _RMP bit | RTC_ALARM _TYPE bit | TAMP1E bit (RTC_TAMP1 input enable) | TSE bit (RTC_TS input enable) |
|-------------------------------------|------------------------------------------|-----------------------------------|------------------|---------------------|-------------------------------------|-------------------------------|
| RTC_ALARM output OD                 | 01 or 10 or 11                           | Don't care                        | 0                | 0                   | Don't care                          | Don't care                    |
|                                     |                                          |                                   | 1                |                     |                                     |                               |
| RTC_ALARM output PP                 | 01 or 10 or 11                           | Don't care                        | 0                | 1                   | Don't care                          | Don't care                    |
|                                     |                                          |                                   | 1                |                     |                                     |                               |
| RTC_CALIB output PP                 | 00                                       | 1                                 | 0                | Don't care          | Don't care                          | Don't care                    |

Table 222. RTC pin PC13 configuration<sup>(1)</sup> (continued)

| PC13 Pin configuration and function | OSEL[1:0] bits (RTC_ALARM output enable) | COE bit (RTC_CALIB output enable) | RTC_OUT_RMP bit | RTC_ALARM_TYPE bit | TAMP1E bit (RTC_TAMP1 input enable) | TSE bit (RTC_TS input enable) |

|                                     | 00                                       | 1                                 | 1               |                    |                                     |                               |
|                                     | 01 or 10 or 11                           | 0                                 |                 |                    |                                     |                               |
| Wakeup pin or Standard GPIO         | 00                                       | 0                                 | Don't care      | Don't care         | 0                                   | 0                             |
|                                     | 00                                       | 1                                 | 1               |                    |                                     |                               |
|                                     | 01 or 10 or 11                           | 0                                 |                 |                    |                                     |                               |

1. OD: open drain; PP: push-pull.

In addition, it is possible to remap RTC\_OUT on PB2 pin thanks to RTC\_OUT\_RMP bit. In this case it is mandatory to configure PB2 GPIO registers as alternate function with the correct type. The remap functions are shown in [Table 223](#).

Table 223. RTC\_OUT mapping

| OSEL[1:0] bits (RTC_ALARM output enable) | COE bit (RTC_CALIB output enable) | RTC_OUT_RMP bit | RTC_OUT on PC13 | RTC_OUT on PB2 |
|------------------------------------------|-----------------------------------|-----------------|-----------------|----------------|
| 00                                       | 0                                 | 0               | -               | -              |
| 00                                       | 1                                 |                 | RTC_CALIB       | -              |

### 38.3.3 Clock and prescalers

The RTC clock source (RTCCLK) is selected through the clock controller among the LSE clock, the LSI oscillator clock, and the HSE clock. For more information on the RTC clock source configuration, refer to [Section 6: Reset and clock control \(RCC\)](#).

A programmable prescaler stage generates a 1 Hz clock which is used to update the calendar. To minimize power consumption, the prescaler is split into 2 programmable prescalers (see [Figure 389: RTC block diagram](#)):

- A 7-bit asynchronous prescaler configured through the PREDIV\_A bits of the RTC\_PRER register.
- A 15-bit synchronous prescaler configured through the PREDIV\_S bits of the RTC\_PRER register.

*Note:* When both prescalers are used, it is recommended to configure the asynchronous prescaler to a high value to minimize consumption.

The asynchronous prescaler division factor is set to 128, and the synchronous division factor to 256, to obtain an internal clock frequency of 1 Hz (ck\_spre) with an LSE frequency of 32.768 kHz.

The minimum division factor is 1 and the maximum division factor is 2<sup>22</sup>.

This corresponds to a maximum input frequency of around 4 MHz.

f<sub>ck\_apre</sub> is given by the following formula:

$$f_{CK\_APRE} = \frac{f_{RTCCLK}}{PREDIV\_A + 1}$$

The ck\_apre clock is used to clock the binary RTC\_SSR subseconds downcounter. When it reaches 0, RTC\_SSR is reloaded with the content of PREDIV\_S.

f<sub>ck\_spre</sub> is given by the following formula:

$$f_{CK\_SPRE} = \frac{f_{RTCCLK}}{(PREDIV\_S + 1) \times (PREDIV\_A + 1)}$$

The `ck_spre` clock can be used either to update the calendar or as timebase for the 16-bit wake-up auto-reload timer. To obtain short timeout periods, the 16-bit wake-up auto-reload timer can also run with the `RTCCLK` divided by the programmable 4-bit asynchronous prescaler (see [Section 38.3.6: Periodic auto-wake-up](#) for details).

### 38.3.4 Real-time clock and calendar

The RTC calendar time and date registers are accessed through shadow registers which are synchronized with `PCLK` (APB clock). They can also be accessed directly in order to avoid waiting for the synchronization duration.

- `RTC_SSR` for the subseconds
- `RTC_TR` for the time
- `RTC_DR` for the date

Every `RTCCLK` period, the current calendar value is copied into the shadow registers, and the `RSF` bit of `RTC_ISR` register is set (see [Section 38.6.4: RTC initialization and status register \(RTC\\_ISR\)](#)). The copy is not performed in Stop and Standby mode. When exiting these modes, the shadow registers are updated after up to 1 `RTCCLK` period.

When the application reads the calendar registers, it accesses the content of the shadow registers. It is possible to make a direct access to the calendar registers by setting the `BYPHAD` control bit in the `RTC_CR` register. By default, this bit is cleared, and the user accesses the shadow registers.

When reading the `RTC_SSR`, `RTC_TR` or `RTC_DR` registers in `BYPHAD=0` mode, the frequency of the APB clock ( $f_{APB}$ ) must be at least 7 times the frequency of the RTC clock ( $f_{RTCCLK}$ ).

The shadow registers are reset by system reset.

### 38.3.5 Programmable alarms

The RTC unit provides programmable alarm: Alarm A and Alarm B. The description below is given for Alarm A, but can be translated in the same way for Alarm B.

The programmable alarm function is enabled through the `ALRAE` bit in the `RTC_CR` register. The `ALRAF` is set to 1 if the calendar subseconds, seconds, minutes, hours, date or day match the values programmed in the alarm registers `RTC_ALRMASR` and `RTC_ALRMAR`. Each calendar field can be independently selected through the `MSKx` bits of the `RTC_ALRMAR` register, and through the `MASKSSx` bits of the `RTC_ALRMASR` register. The alarm interrupt is enabled through the `ALRAIE` bit in the `RTC_CR` register.

**Caution:** If the seconds field is selected (`MSK1` bit reset in `RTC_ALRMAR`), the synchronous prescaler division factor set in the `RTC_PRER` register must be at least 3 to ensure correct behavior.

Alarm A and Alarm B (if enabled by bits `OSEL[1:0]` in `RTC_CR` register) can be routed to the `RTC_ALARM` output. `RTC_ALARM` output polarity can be configured through bit `POL` the `RTC_CR` register.

### 38.3.6 Periodic auto-wake-up

The periodic wake-up flag is generated by a 16-bit programmable auto-reload down-counter. The wake-up timer range can be extended to 17 bits.

The wake-up function is enabled through the `WUTE` bit in the `RTC_CR` register.

The wake-up timer clock input can be:

- RTC clock (RTCCLK) divided by 2, 4, 8, or 16.  
When RTCCLK is LSE(32.768 kHz), this allows to configure the wake-up interrupt period from 122  $\mu$ s to 32 s, with a resolution down to 61  $\mu$ s.
- ck\_spre (usually 1 Hz internal clock)  
When ck\_spre frequency is 1Hz, this allows to achieve a wake-up time from 1 s to around 36 hours with one-second resolution. This large programmable time range is divided in 2 parts:
  - from 1s to 18 hours when WUCKSEL[2:1] = 10
  - and from around 18h to 36h when WUCKSEL[2:1] = 11. In this last case 2<sup>16</sup> is added to the 16-bit counter current value. When the initialization sequence is complete (see [Programming the wake-up timer on page 1219](#)), the timer starts counting down. When the wake-up function is enabled, the down-counting remains active in low-power modes. In addition, when it reaches 0, the WUTF flag is set in the RTC\_ISR register, and the wake-up counter is automatically reloaded with its reload value (RTC\_WUTR register value).

The WUTF flag must then be cleared by software.

When the periodic wake-up interrupt is enabled by setting the WUTIE bit in the RTC\_CR register, it can exit the device from low-power modes.

The periodic wake-up flag can be routed to the RTC\_ALARM output provided it has been enabled through bits OSEL[1:0] of RTC\_CR register. RTC\_ALARM output polarity can be configured through the POL bit in the RTC\_CR register.

System reset, as well as low-power modes (Sleep, Stop and Standby) have no influence on the wake-up timer.

### 38.3.7 RTC initialization and configuration

#### RTC register access

The RTC registers are 32-bit registers. The APB interface introduces 2 wait-states in RTC register accesses except on read accesses to calendar shadow registers when BYPSHAD=0.

#### RTC register write protection

After system reset, the RTC registers are protected against parasitic write access by clearing the DBP bit in the PWR\_CR1 register (refer to the power control section). DBP bit must be set in order to enable RTC registers write access.

After Backup domain reset, all the RTC registers are write-protected. Writing to the RTC registers is enabled by writing a key into the Write Protection register, RTC\_WPR.

The following steps are required to unlock the write protection on all the RTC registers except for RTC\_TAMPCR, RTC\_BKPxR, RTC\_OR and RTC\_ISR[31:8].

1. Write '0xCA' into the RTC\_WPR register.
2. Write '0x53' into the RTC\_WPR register.

Writing a wrong key reactivates the write protection.

The protection mechanism is not affected by system reset.

## Calendar initialization and configuration

To program the initial time and date calendar values, including the time format and the prescaler configuration, the following sequence is required:

1. Set INIT bit to 1 in the RTC\_ISR register to enter initialization mode. In this mode, the calendar counter is stopped and its value can be updated.
2. Poll INITF bit of in the RTC\_ISR register. The initialization phase mode is entered when INITF is set to 1. It takes around 2 RTCCLK clock cycles (due to clock synchronization).
3. To generate a 1 Hz clock for the calendar counter, program both the prescaler factors in RTC\_PRER register.
4. Load the initial time and date values in the shadow registers (RTC\_TR and RTC\_DR), and configure the time format (12 or 24 hours) through the FMT bit in the RTC\_CR register.
5. Exit the initialization mode by clearing the INIT bit. The actual calendar counter value is then automatically loaded and the counting restarts after 4 RTCCLK clock cycles.

When the initialization sequence is complete, the calendar starts counting.

*Note: After a system reset, the application can read the INITS flag in the RTC\_ISR register to check if the calendar has been initialized or not. If this flag equals 0, the calendar has not been initialized since the year field is set at its Backup domain reset default value (0x00). To read the calendar after initialization, the software must first check that the RSF flag is set in the RTC\_ISR register.*

## Daylight saving time

The daylight saving time management is performed through bits SUB1H, ADD1H, and BKP of the RTC\_CR register.

Using SUB1H or ADD1H, the software can subtract or add one hour to the calendar in one single operation without going through the initialization procedure.

In addition, the software can use the BKP bit to memorize this operation.

## Programming the alarm

A similar procedure must be followed to program or update the programmable alarms. The procedure below is given for Alarm A but can be translated in the same way for Alarm B.

1. Clear ALRAE in RTC\_CR to disable Alarm A.
2. Program the Alarm A registers (RTC\_ALRMASR/RTC\_ALRMAR).
3. Set ALRAE in the RTC\_CR register to enable Alarm A again.

*Note: Each change of the RTC\_CR register is taken into account after around 2 RTCCLK clock cycles due to clock synchronization.*

## Programming the wake-up timer

The following sequence is required to configure or change the wake-up timer auto-reload value (WUT[15:0] in RTC\_WUTR):

1. Clear WUTE in RTC\_CR to disable the wake-up timer.
2. Poll WUTWF until it is set in RTC\_ISR to make sure the access to wake-up auto-reload counter and to WUCKSEL[2:0] bits is allowed. It takes around 2 RTCCLK clock cycles (due to clock synchronization).
3. Program the wake-up auto-reload value WUT[15:0], and the wake-up clock selection (WUCKSEL[2:0] bits in RTC\_CR). Set WUTE in RTC\_CR to enable the timer again. The wake-up timer restarts down-counting. The WUTWF bit is cleared up to 2 RTCCLK clock cycles after WUTE is cleared, due to clock synchronization.

### 38.3.8 Reading the calendar

#### When BYPSHAD control bit is cleared in the RTC\_CR register

To read the RTC calendar registers (RTC\_SSR, RTC\_TR and RTC\_DR) properly, the APB clock frequency ( $f_{PCLK}$ ) must be equal to or greater than seven times the RTC clock frequency ( $f_{RTCCLK}$ ). This ensures a secure behavior of the synchronization mechanism.

If the APB clock frequency is less than seven times the RTC clock frequency, the software must read the calendar time and date registers twice. If the second read of the RTC\_TR gives the same result as the first read, this ensures that the data is correct. Otherwise a third read access must be done. In any case the APB clock frequency must never be lower than the RTC clock frequency.

The RSF bit is set in RTC\_ISR register each time the calendar registers are copied into the RTC\_SSR, RTC\_TR and RTC\_DR shadow registers. The copy is performed every RTCCLK cycle. To ensure consistency between the 3 values, reading either RTC\_SSR or RTC\_TR locks the values in the higher-order calendar shadow registers until RTC\_DR is read. In case the software makes read accesses to the calendar in a time interval smaller than 1 RTCCLK period: RSF must be cleared by software after the first calendar read, and then the software must wait until RSF is set before reading again the RTC\_SSR, RTC\_TR and RTC\_DR registers.

After waking up from low-power mode (Stop or Standby), RSF must be cleared by software. The software must then wait until it is set again before reading the RTC\_SSR, RTC\_TR and RTC\_DR registers.

The RSF bit must be cleared after wake-up and not before entering low-power mode.

After a system reset, the software must wait until RSF is set before reading the RTC\_SSR, RTC\_TR and RTC\_DR registers. Indeed, a system reset resets the shadow registers to their default values.

After an initialization (refer to [Calendar initialization and configuration on page 1219](#)): the software must wait until RSF is set before reading the RTC\_SSR, RTC\_TR and RTC\_DR registers.

After synchronization (refer to [Section 38.3.10: RTC synchronization](#)): the software must wait until RSF is set before reading the RTC\_SSR, RTC\_TR and RTC\_DR registers.

#### When the BYPSHAD control bit is set in the RTC\_CR register (bypass shadow registers)

Reading the calendar registers gives the values from the calendar counters directly, thus eliminating the need to wait for the RSF bit to be set. This is especially useful after exiting from low-power modes (STOP or Standby), since the shadow registers are not updated during these modes.

When the BYPSHAD bit is set to 1, the results of the different registers might not be coherent with each other if an RTCCLK edge occurs between two read accesses to the registers. Additionally, the value of one of the registers may be incorrect if an RTCCLK edge occurs during the read operation. The software must read all the registers twice, and then compare the results to confirm that the data is coherent and correct. Alternatively, the software can just compare the two results of the least-significant calendar register.

*Note:* While BYPSHAD=1, instructions which read the calendar registers require one extra APB cycle to complete.

### 38.3.9 Resetting the RTC

The calendar shadow registers (RTC\_SSR, RTC\_TR and RTC\_DR) and some bits of the RTC status register (RTC\_ISR) are reset to their default values by all available system reset sources.

On the contrary, the following registers are reset to their default values by a Backup domain reset and are not affected by a system reset: the RTC current calendar registers, the RTC control register (RTC\_CR), the prescaler register (RTC\_PRER), the RTC calibration register (RTC\_CALR), the RTC shift register (RTC\_SHIFTR), the RTC timestamp registers (RTC\_TSSSR, RTC\_TSTR and RTC\_TSDR), the RTC tamper configuration register (RTC\_TAMPCR), the RTC backup registers (RTC\_BKPxR), the wake-up timer register (RTC\_WUTR), the Alarm A and Alarm B registers (RTC\_ALRMASSR/RTC\_ALRMAR and RTC\_ALRMBSSR/RTC\_ALRMBR), and the Option register (RTC\_OR).

In addition, when it is clocked by the LSE, the RTC keeps on running under system reset if the reset source is different from the Backup domain reset one (refer to the RTC clock section of the Reset and clock controller for details on the list of RTC clock sources not affected by system reset). When a Backup domain reset occurs, the RTC is stopped and all the RTC registers are set to their reset values.

### 38.3.10 RTC synchronization

The RTC can be synchronized to a remote clock with a high degree of precision. After reading the sub-second field (RTC\_SSR or RTC\_TSSSR), a calculation can be made of the precise offset between the times being maintained by the remote clock and the RTC. The RTC can then be adjusted to eliminate this offset by “shifting” its clock by a fraction of a second using RTC\_SHIFTR.

RTC\_SSR contains the value of the synchronous prescaler counter. This allows one to calculate the exact time being maintained by the RTC down to a resolution of  $1 / (\text{PREDIV\_S} + 1)$  seconds. As a consequence, the resolution can be improved by increasing the synchronous prescaler value (PREDIV\_S[14:0]). The maximum resolution allowed (30.52  $\mu$ s with a 32768 Hz clock) is obtained with PREDIV\_S set to 0x7FFF.

However, increasing PREDIV\_S means that PREDIV\_A must be decreased in order to maintain the synchronous prescaler output at 1 Hz. In this way, the frequency of the asynchronous prescaler output increases, which may increase the RTC dynamic consumption.

The RTC can be finely adjusted using the RTC shift control register (RTC\_SHIFTR). Writing to RTC\_SHIFTR can shift (either delay or advance) the clock by up to a second with a resolution of  $1 / (\text{PREDIV\_S} + 1)$  seconds. The shift operation consists of adding the SUBFS[14:0] value to the synchronous prescaler counter SS[15:0]: this will delay the clock.

If at the same time the ADD1S bit is set, this results in adding one second and at the same time subtracting a fraction of second, so this will advance the clock.

**Caution:** Before initiating a shift operation, the user must check that SS[15] = 0 in order to ensure that no overflow will occur.

As soon as a shift operation is initiated by a write to the RTC\_SHIFTR register, the SHPF flag is set by hardware to indicate that a shift operation is pending. This bit is cleared by hardware as soon as the shift operation has completed.

**Caution:** This synchronization feature is not compatible with the reference clock detection feature: firmware must not write to RTC\_SHIFTR when REFCKON=1.

### 38.3.11 RTC reference clock detection

The update of the RTC calendar can be synchronized to a reference clock, RTC\_REFIN, which is usually the mains frequency (50 or 60 Hz). The precision of the RTC\_REFIN reference clock should be higher than the 32.768 kHz LSE clock. When the RTC\_REFIN detection is enabled (REFCKON bit of RTC\_CR set to 1), the calendar is still clocked by the LSE, and RTC\_REFIN is used to compensate for the imprecision of the calendar update frequency (1 Hz).

Each 1 Hz clock edge is compared to the nearest RTC\_REFIN clock edge (if one is found within a given time window). In most cases, the two clock edges are properly aligned. When the 1 Hz clock becomes misaligned due to the imprecision of the LSE clock, the RTC shifts the 1 Hz clock a bit so that future 1 Hz clock edges are aligned. Thanks to this mechanism, the calendar becomes as precise as the reference clock.

The RTC detects if the reference clock source is present by using the 256 Hz clock (ck\_apre) generated from the 32.768 kHz quartz. The detection is performed during a time window around each of the calendar updates (every 1 s). The window equals 7 ck\_apre periods when detecting the first reference clock edge. A smaller window of 3 ck\_apre periods is used for subsequent calendar updates.

Each time the reference clock is detected in the window, the synchronous prescaler which outputs the ck\_spre clock is forced to reload. This has no effect when the reference clock and the 1 Hz clock are aligned because the prescaler is being reloaded at the same moment. When the clocks are not aligned, the reload shifts future 1 Hz clock edges a little for them to be aligned with the reference clock.

If the reference clock halts (no reference clock edge occurred during the 3 ck\_apre window), the calendar is updated continuously based solely on the LSE clock. The RTC then waits for the reference clock using a large 7 ck\_apre period detection window centered on the ck\_spre edge.

When the RTC\_REFIN detection is enabled, PREDIV\_A and PREDIV\_S must be set to their default values:

- PREDIV\_A = 0x007F
- PREDIV\_S = 0x00FF

*Note:* RTC\_REFIN clock detection is not available in Standby mode.

### 38.3.12 RTC smooth digital calibration

The RTC frequency can be digitally calibrated with a resolution of about 0.954 ppm with a range from -487.1 ppm to +488.5 ppm. The correction of the frequency is performed using

series of small adjustments (adding and/or subtracting individual RTCCLK pulses). These adjustments are fairly well distributed so that the RTC is well calibrated even when observed over short durations of time.

The smooth digital calibration is performed during a cycle of about  $2^{20}$  RTCCLK pulses, or 32 seconds when the input frequency is 32768 Hz. This cycle is maintained by a 20-bit counter, `cal_cnt[19:0]`, clocked by RTCCLK.

The smooth calibration register (RTC\_CALR) specifies the number of RTCCLK clock cycles to be masked during the 32-second cycle:

- Setting the bit CALM[0] to 1 causes exactly one pulse to be masked during the 32-second cycle.
- Setting CALM[1] to 1 causes two additional cycles to be masked
- Setting CALM[2] to 1 causes four additional cycles to be masked
- and so on up to CALM[8] set to 1 which causes 256 clocks to be masked.

**Note:** *CALM[8:0] (RTC\_CALR) specifies the number of RTCCLK pulses to be masked during the 32-second cycle. Setting the bit CALM[0] to '1' causes exactly one pulse to be masked during the 32-second cycle at the moment when `cal_cnt[19:0]` is 0x80000; CALM[1]=1 causes two other cycles to be masked (when `cal_cnt` is 0x40000 and 0xC0000); CALM[2]=1 causes four other cycles to be masked (`cal_cnt` = 0x20000/0x60000/0xA0000/ 0xE0000); and so on up to CALM[8]=1 which causes 256 clocks to be masked (`cal_cnt` = 0xFF800).*

While CALM allows the RTC frequency to be reduced by up to 487.1 ppm with fine resolution, the bit CALP can be used to increase the frequency by 488.5 ppm. Setting CALP to '1' effectively inserts an extra RTCCLK pulse every  $2^{11}$  RTCCLK cycles, which means that 512 clocks are added during every 32-second cycle.

Using CALM together with CALP, an offset ranging from -511 to +512 RTCCLK cycles can be added during the 32-second cycle, which translates to a calibration range of -487.1 ppm to +488.5 ppm with a resolution of about 0.954 ppm.

The formula to calculate the effective calibrated frequency (FCAL) given the input frequency (FRTCCLK) is as follows:

$$F_{\text{CAL}} = F_{\text{RTCCLK}} \times [1 + (\text{CALP} \times 512 - \text{CALM}) / (2^{20} + \text{CALM} - \text{CALP} \times 512)]$$

### Calibration when PREDIV\_A < 3

The CALP bit can not be set to 1 when the asynchronous prescaler value (PREDIV\_A bits in RTC\_PRER register) is less than 3. If CALP was already set to 1 and PREDIV\_A bits are set to a value less than 3, CALP is ignored and the calibration operates as if CALP was equal to 0.

To perform a calibration with PREDIV\_A less than 3, the synchronous prescaler value (PREDIV\_S) should be reduced so that each second is accelerated by 8 RTCCLK clock cycles, which is equivalent to adding 256 clock cycles every 32 seconds. As a result, between 255 and 256 clock pulses (corresponding to a calibration range from 243.3 to 244.1 ppm) can effectively be added during each 32-second cycle using only the CALM bits.

With a nominal RTCCLK frequency of 32768 Hz, when PREDIV\_A equals 1 (division factor of 2), PREDIV\_S should be set to 16379 rather than 16383 (4 less). The only other interesting case is when PREDIV\_A equals 0, PREDIV\_S should be set to 32759 rather than 32767 (8 less).

If PREDIV\_S is reduced in this way, the formula given the effective frequency of the

calibrated input clock is as follows:

$$F_{CAL} = F_{RTCCLK} \times [1 + (256 - CALM) / (2^{20} + CALM - 256)]$$

In this case, CALM[7:0] equals 0x100 (the midpoint of the CALM range) is the correct setting if RTCCLK is exactly 32768.00 Hz.

### Verifying the RTC calibration

RTC precision is ensured by measuring the precise frequency of RTCCLK and calculating the correct CALM value and CALP values. An optional 1 Hz output is provided to allow applications to measure and verify the RTC precision.

Measuring the precise frequency of the RTC over a limited interval can result in a measurement error of up to 2 RTCCLK clock cycles over the measurement period, depending on how the digital calibration cycle is aligned with the measurement period.

However, this measurement error can be eliminated if the measurement period is the same length as the calibration cycle period. In this case, the only error observed is the error due to the resolution of the digital calibration.

- By default, the calibration cycle period is 32 seconds.

Using this mode and measuring the accuracy of the 1 Hz output over exactly 32 seconds guarantees that the measure is within 0.477 ppm (0.5 RTCCLK cycles over 32 seconds, due to the limitation of the calibration resolution).

- CALW16 bit of the RTC\_CALR register can be set to 1 to force a 16- second calibration cycle period.

In this case, the RTC precision can be measured during 16 seconds with a maximum error of 0.954 ppm (0.5 RTCCLK cycles over 16 seconds). However, since the calibration resolution is reduced, the long term RTC precision is also reduced to 0.954 ppm: CALM[0] bit is stuck at 0 when CALW16 is set to 1.

- CALW8 bit of the RTC\_CALR register can be set to 1 to force a 8- second calibration cycle period.

In this case, the RTC precision can be measured during 8 seconds with a maximum error of 1.907 ppm (0.5 RTCCLK cycles over 8s). The long term RTC precision is also reduced to 1.907 ppm: CALM[1:0] bits are stuck at 00 when CALW8 is set to 1.

### Re-calibration on-the-fly

The calibration register (RTC\_CALR) can be updated on-the-fly while RTC\_ISR/INITF=0, by using the follow process:

1. Poll the RTC\_ISR/RECALPF (re-calibration pending flag).
2. If it is set to 0, write a new value to RTC\_CALR, if necessary. RECALPF is then automatically set to 1
3. Within three ck\_apre cycles after the write operation to RTC\_CALR, the new calibration settings take effect.

### 38.3.13 Time-stamp function

Time-stamp is enabled by setting the TSE or ITSE bits of RTC\_CR register to 1.

When TSE is set:

The calendar is saved in the time-stamp registers (RTC\_TSSSR, RTC\_TSTR, RTC\_TSDR) when a time-stamp event is detected on the RTC\_TS pin.

When ITSE is set:

The calendar is saved in the time-stamp registers (RTC\_TSSSR, RTC\_TSTR, RTC\_TSDR) when an internal time-stamp event is detected. The internal timestamp event is generated by the switch to the VBAT supply.

When a time-stamp event occurs, due to internal or external event, the time-stamp flag bit (TSF) in RTC\_ISR register is set. In case the event is internal, the ITSF flag is also set in RTC\_ISR register.

By setting the TSIE bit in the RTC\_CR register, an interrupt is generated when a time-stamp event occurs.

If a new time-stamp event is detected while the time-stamp flag (TSF) is already set, the time-stamp overflow flag (TSOVF) flag is set and the time-stamp registers (RTC\_TSTR and RTC\_TSDR) maintain the results of the previous event.

**Note:** *TSF is set 2  $ck_{apre}$  cycles after the time-stamp event occurs due to synchronization process.*

*There is no delay in the setting of TSOVF. This means that if two time-stamp events are close together, TSOVF can be seen as '1' while TSF is still '0'. As a consequence, it is recommended to poll TSOVF only after TSF has been set.*

**Caution:** If a time-stamp event occurs immediately after the TSF bit is supposed to be cleared, then both TSF and TSOVF bits are set. To avoid masking a time-stamp event occurring at the same moment, the application must not write '0' into TSF bit unless it has already read it to '1'.

Optionally, a tamper event can cause a time-stamp to be recorded. See the description of the TAMPTS control bit in [Section 38.6.16: RTC tamper configuration register \(RTC\\_TAMPCR\)](#).

### 38.3.14 Tamper detection

The RTC\_TAMPx input events can be configured either for edge detection, or for level detection with filtering.

The tamper detection can be configured for the following purposes:

- erase the RTC backup registers (default configuration)
- generate an interrupt, capable to wake-up from Stop and Standby modes
- generate a hardware trigger for the low-power timers

#### RTC backup registers

The backup registers (RTC\_BKPxR) are not reset by system reset or when the device wakes up from Standby mode.

The backup registers are reset when a tamper detection event occurs (see [Section 38.6.20: RTC backup registers \(RTC\\_BKPxR\)](#) and [Tamper detection initialization on page 1226](#)) except if the TAMPxNOERASE bit is set, or if TAMPxMF is set in the RTC\_TAMPCR register.

### Tamper detection initialization

Each input can be enabled by setting the corresponding TAMPxE bits to 1 in the RTC\_TAMPCR register.

Each RTC\_TAMPx tamper detection input is associated with a flag TAMPxF in the RTC\_ISR register.

When TAMPxMF is cleared:

The TAMPxF flag is asserted after the tamper event on the pin, with the latency provided below:

- 3 ck\_apre cycles when TAMPFLT differs from 0x0 (Level detection with filtering)
- 3 ck\_apre cycles when TAMPTS=1 (Timestamp on tamper event)
- No latency when TAMPFLT=0x0 (Edge detection) and TAMPTS=0

A new tamper occurring on the same pin during this period and as long as TAMPxF is set cannot be detected.

When TAMPxMF is set:

A new tamper occurring on the same pin cannot be detected during the latency described above and 2.5 ck\_rtc additional cycles.

By setting the TAMPIE bit in the RTC\_TAMPCR register, an interrupt is generated when a tamper detection event occurs (when TAMPxF is set). Setting TAMPIE is not allowed when one or more TAMPxMF is set.

When TAMPIE is cleared, each tamper pin event interrupt can be individually enabled by setting the corresponding TAMPxIE bit in the RTC\_TAMPCR register. Setting TAMPxIE is not allowed when the corresponding TAMPxMF is set.

### Trigger output generation on tamper event

The tamper event detection can be used as trigger input by the low-power timers.

When TAMPxMF bit is cleared in RTC\_TAMPCR register, the TAMPxF flag must be cleared by software in order to allow a new tamper detection on the same pin.

When TAMPxMF bit is set, the TAMPxF flag is masked, and kept cleared in RTC\_ISR register. This configuration allows to trigger automatically the low-power timers in Stop mode, without requiring the system wakeup to perform the TAMPxF clearing. In this case, the backup registers are not cleared.

### Timestamp on tamper event

With TAMPTS set to '1', any tamper event causes a timestamp to occur. In this case, either the TSF bit or the TSOVF bit are set in RTC\_ISR, in the same manner as if a normal timestamp event occurs. The affected tamper flag register TAMPxF is set at the same time that TSF or TSOVF is set.

### Edge detection on tamper inputs

If the TAMPFLT bits are "00", the RTC\_TAMPx pins generate tamper detection events when either a rising edge or a falling edge is observed depending on the corresponding TAMPxTRG bit. The internal pull-up resistors on the RTC\_TAMPx inputs are deactivated when edge detection is selected.

**Caution:** When using the edge detection, it is recommended to check by software the tamper pin level just after enabling the tamper detection (by reading the GPIO registers), and before writing sensitive values in the backup registers, to ensure that an active edge did not occur before enabling the tamper event detection.  
When TAMPFLT="00" and TAMPxTRG = 0 (rising edge detection), a tamper event may be detected by hardware if the tamper input is already at high level before enabling the tamper detection.

After a tamper event has been detected and cleared, the RTC\_TAMPx should be disabled and then re-enabled (TAMPxE set to 1) before re-programming the backup registers (RTC\_BKPxR). This prevents the application from writing to the backup registers while the RTC\_TAMPx input value still indicates a tamper detection. This is equivalent to a level detection on the RTC\_TAMPx input.

**Note:** *Tamper detection is still active when  $V_{DD}$  power is switched off. To avoid unwanted resetting of the backup registers, the pin to which the RTC\_TAMPx is mapped should be externally tied to the correct level.*

### Level detection with filtering on RTC\_TAMPx inputs

Level detection with filtering is performed by setting TAMPFLT to a non-zero value. A tamper detection event is generated when either 2, 4, or 8 (depending on TAMPFLT) consecutive samples are observed at the level designated by the TAMPxTRG bits.

The RTC\_TAMPx inputs are precharged through the I/O internal pull-up resistance before its state is sampled, unless disabled by setting TAMPPUDIS to 1. The duration of the precharge is determined by the TAMPPRCH bits, allowing for larger capacitances on the RTC\_TAMPx inputs.

The trade-off between tamper detection latency and power consumption through the pull-up can be optimized by using TAMPFREQ to determine the frequency of the sampling for level detection.

**Note:** *Refer to the datasheets for the electrical characteristics of the pull-up resistors.*

## 38.3.15 Calibration clock output

When the COE bit is set to 1 in the RTC\_CR register, a reference clock is provided on the RTC\_CALIB device output.

If the COSEL bit in the RTC\_CR register is reset and PREDIV\_A = 0x7F, the RTC\_CALIB frequency is  $f_{\text{RTCCLK}}/64$ . This corresponds to a calibration output at 512 Hz for an RTCCLK frequency at 32.768 kHz. The RTC\_CALIB duty cycle is irregular: there is a light jitter on falling edges. It is therefore recommended to use rising edges.

When COSEL is set and "PREDIV\_S+1" is a non-zero multiple of 256 (i.e: PREDIV\_S[7:0] = 0xFF), the RTC\_CALIB frequency is  $f_{\text{RTCCLK}}/(256 * (\text{PREDIV\_A}+1))$ . This corresponds to a calibration output at 1 Hz for prescaler default values (PREDIV\_A = 0x7F, PREDIV\_S = 0xFF), with an RTCCLK frequency at 32.768 kHz. The 1 Hz output is affected when a shift operation is on going and may toggle during the shift operation (SHPF=1).

**Note:** *When COSEL bit is cleared, the RTC\_CALIB output is the output of the 6th stage of the asynchronous prescaler.*

*When COSEL bit is set, the RTC\_CALIB output is the output of the 8th stage of the synchronous prescaler.*

### 38.3.16 Alarm output

The OSEL[1:0] control bits in the RTC\_CR register are used to activate the alarm output RTC\_ALARM, and to select the function which is output. These functions reflect the contents of the corresponding flags in the RTC\_ISR register.

The polarity of the output is determined by the POL control bit in RTC\_CR so that the opposite of the selected flag bit is output when POL is set to 1.

#### Alarm output

The RTC\_ALARM pin can be configured in output open drain or output push-pull using RTC\_OR register.

*Note:* Once the RTC\_ALARM output is enabled, it has priority over RTC\_CALIB (COE bit is don't care and must be kept cleared).

## 38.4 RTC low-power modes

**Table 225. Effect of low-power modes on RTC**

| Mode            | Description                                                                                                                                                                 |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Sleep           | No effect<br>RTC interrupts cause the device to exit the Sleep mode.                                                                                                        |
| Low-power run   | No effect.                                                                                                                                                                  |
| Low-power sleep | No effect. RTC interrupts cause the device to exit the Low-power sleep mode.                                                                                                |
| Stop 0          | The RTC remains active when the RTC clock source is LSE or LSI. RTC alarm, RTC tamper event, RTC timestamp event, and RTC Wakeup cause the device to exit the Stop mode.    |
| Stop 1          |                                                                                                                                                                             |
| Stop 2          |                                                                                                                                                                             |
| Standby         | The RTC remains active when the RTC clock source is LSE or LSI. RTC alarm, RTC tamper event, RTC timestamp event, and RTC Wakeup cause the device to exit the Standby mode. |
| Shutdown        | The RTC remains active when the RTC clock source is LSE. RTC alarm, RTC tamper event, RTC timestamp event, and RTC Wakeup cause the device to exit the Shutdown mode.       |

## 38.5 RTC interrupts

All RTC interrupts are connected to the EXTI controller. Refer to [Section 14: Extended interrupts and events controller \(EXTI\)](#).

To enable the RTC Alarm interrupt, the following sequence is required:

1. Configure and enable the EXTI line corresponding to the RTC Alarm event in interrupt mode and select the rising edge sensitivity.
2. Configure and enable the RTC\_ALARM IRQ channel in the NVIC.
3. Configure the RTC to generate RTC alarms.

To enable the RTC Tamper interrupt, the following sequence is required:

1. Configure and enable the EXTI line corresponding to the RTC Tamper event in interrupt mode and select the rising edge sensitivity.
2. Configure and Enable the RTC\_TAMP\_STAMP IRQ channel in the NVIC.
3. Configure the RTC to detect the RTC tamper event.

To enable the RTC TimeStamp interrupt, the following sequence is required:

1. Configure and enable the EXTI line corresponding to the RTC TimeStamp event in interrupt mode and select the rising edge sensitivity.
2. Configure and Enable the RTC\_TAMP\_STAMP IRQ channel in the NVIC.
3. Configure the RTC to detect the RTC time-stamp event.

To enable the Wakeup timer interrupt, the following sequence is required:

1. Configure and enable the EXTI line corresponding to the Wakeup timer even in interrupt mode and select the rising edge sensitivity.
2. Configure and Enable the RTC\_WKUP IRQ channel in the NVIC.
3. Configure the RTC to detect the RTC Wakeup timer event.

**Table 226. Interrupt control bits**

| Interrupt event           | Event flag | Enable control bit | Exit from Sleep mode | Exit from Stop mode | Exit from Standby mode |
|---------------------------|------------|--------------------|----------------------|---------------------|------------------------|
| Alarm A                   | ALRAF      | ALRAIE             | Yes                  | Yes <sup>(1)</sup>  | Yes <sup>(1)</sup>     |
| Alarm B                   | ALRBF      | ALRBIE             | Yes                  | Yes <sup>(1)</sup>  | Yes <sup>(1)</sup>     |
| RTC_TS input (timestamp)  | TSF        | TSIE               | Yes                  | Yes <sup>(1)</sup>  | Yes <sup>(1)</sup>     |
| RTC_TAMP1 input detection | TAMP1F     | TAMPIE             | Yes                  | Yes <sup>(1)</sup>  | Yes <sup>(1)</sup>     |
| RTC_TAMP2 input detection | TAMP2F     | TAMPIE             | Yes                  | Yes <sup>(1)</sup>  | Yes <sup>(1)</sup>     |
| RTC_TAMP3 input detection | TAMP3F     | TAMPIE             | Yes                  | Yes <sup>(1)</sup>  | Yes <sup>(1)</sup>     |
| Wakeup timer interrupt    | WUTF       | WUTIE              | Yes                  | Yes <sup>(1)</sup>  | Yes <sup>(1)</sup>     |

1. Wakeup from STOP and Standby modes is possible only when the RTC clock source is LSE or LSI.

## 38.6 RTC registers

Refer to [Section 1.2 on page 69](#) of the reference manual for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by words (32-bit).

### 38.6.1 RTC time register (RTC\_TR)

The RTC\_TR is the calendar time shadow register. This register must be written in initialization mode only. Refer to [Calendar initialization and configuration on page 1219](#) and [Reading the calendar on page 1220](#).

This register is write protected. The write access procedure is described in [RTC register write protection on page 1218](#).

Address offset: 0x00

Backup domain reset value: 0x0000 0000

System reset: 0x0000 0000 when BYPSHAD = 0. Not affected when BYPSHAD = 1.

|      |          |      |      |          |      |      |      |      |         |         |    |         |    |    |    |

Bits 31:23 Reserved, must be kept at reset value.

Bit 22 **PM**: AM/PM notation

0: AM or 24-hour format

1: PM

Bits 21:20 **HT[1:0]**: Hour tens in BCD format

Bits 19:16 **HU[3:0]**: Hour units in BCD format

Bit 15 Reserved, must be kept at reset value.

Bits 14:12 **MNT[2:0]**: Minute tens in BCD format

Bits 11:8 **MNU[3:0]**: Minute units in BCD format

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **ST[2:0]**: Second tens in BCD format

Bits 3:0 **SU[3:0]**: Second units in BCD format

### 38.6.2 RTC date register (RTC\_DR)

The RTC\_DR is the calendar date shadow register. This register must be written in initialization mode only. Refer to [Calendar initialization and configuration on page 1219](#) and [Reading the calendar on page 1220](#).

This register is write protected. The write access procedure is described in [RTC register write protection on page 1218](#).

Address offset: 0x04

Backup domain reset value: 0x0000 2101

System reset: 0x0000 2101 when BYPSHAD = 0. Not affected when BYPSHAD = 1.

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:20 **YT[3:0]**: Year tens in BCD format

Bits 19:16 **YU[3:0]**: Year units in BCD format

Bits 15:13 **WDU[2:0]**: Week day units

000: forbidden

001: Monday

...

111: Sunday

Bit 12 **MT**: Month tens in BCD format

Bits 11:8 **MU[3:0]**: Month units in BCD format

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **DT[1:0]**: Date tens in BCD format

Bits 3:0 **DU[3:0]**: Date units in BCD format

### 38.6.3 RTC control register (RTC\_CR)

Address offset: 0x08

Backup domain reset value: 0x0000 0000

System reset: not affected

| 31   | 30    | 29     | 28     | 27   | 26   | 25    | 24    | 23   | 22        | 21      | 20      | 19     | 18           | 17    | 16    |

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **ITSE**: timestamp on internal event enable

0: internal event timestamp disabled

1: internal event timestamp enabled

Bit 23 **COE**: Calibration output enable

This bit enables the RTC\_CALIB output

0: Calibration output disabled

1: Calibration output enabled

Bits 22:21 **OSEL[1:0]**: Output selection

These bits are used to select the flag to be routed to RTC\_ALARM output

00: Output disabled

01: Alarm A output enabled

10: Alarm B output enabled

11: Wake-up output enabled

Bit 20 **POL**: Output polarity

This bit is used to configure the polarity of RTC\_ALARM output

0: The pin is high when ALRAF/ALRBF/WUTF is asserted (depending on OSEL[1:0])

1: The pin is low when ALRAF/ALRBF/WUTF is asserted (depending on OSEL[1:0]).

Bit 19 **COSEL**: Calibration output selection

When COE=1, this bit selects which signal is output on RTC\_CALIB.

0: Calibration output is 512 Hz (with default prescaler setting)

1: Calibration output is 1 Hz (with default prescaler setting)

These frequencies are valid for RTCCLK at 32.768 kHz and prescalers at their default values (PREDIV\_A=127 and PREDIV\_S=255). Refer to [Section 38.3.15: Calibration clock output](#)

Bit 18 **BKP**: Backup

This bit can be written by the user to memorize whether the daylight saving time change has been performed or not.

- Bit 17 **SUB1H**: Subtract 1 hour (winter time change)  
When this bit is set, 1 hour is subtracted to the calendar time if the current hour is not 0. This bit is always read as 0.  
Setting this bit has no effect when current hour is 0.  
0: No effect  
1: Subtracts 1 hour to the current time. This can be used for winter time change outside initialization mode.
- Bit 16 **ADD1H**: Add 1 hour (summer time change)  
When this bit is set, 1 hour is added to the calendar time. This bit is always read as 0.  
0: No effect  
1: Adds 1 hour to the current time. This can be used for summer time change outside initialization mode.
- Bit 15 **TSIE**: Time-stamp interrupt enable  
0: Time-stamp Interrupt disable  
1: Time-stamp Interrupt enable
- Bit 14 **WUTIE**: Wake-up timer interrupt enable  
0: Wake-up timer interrupt disabled  
1: Wake-up timer interrupt enabled
- Bit 13 **ALRBIE**: Alarm B interrupt enable  
0: Alarm B Interrupt disable  
1: Alarm B Interrupt enable
- Bit 12 **ALRAIE**: Alarm A interrupt enable  
0: Alarm A interrupt disabled  
1: Alarm A interrupt enabled
- Bit 11 **TSE**: timestamp enable  
0: timestamp disable  
1: timestamp enable
- Bit 10 **WUTE**: Wake-up timer enable  
0: Wake-up timer disabled  
1: Wake-up timer enabled  
*Note: When the wake-up timer is disabled, wait for WUTWF=1 before enabling it again.*
- Bit 9 **ALRBE**: Alarm B enable  
0: Alarm B disabled  
1: Alarm B enabled
- Bit 8 **ALRAE**: Alarm A enable  
0: Alarm A disabled  
1: Alarm A enabled
- Bit 7 Reserved, must be kept at reset value.
- Bit 6 **FMT**: Hour format  
0: 24 hour/day format  
1: AM/PM hour format

Bit 5 **BYPHAD**: Bypass the shadow registers

0: Calendar values (when reading from RTC\_SSR, RTC\_TR, and RTC\_DR) are taken from the shadow registers, which are updated once every two RTCCLK cycles.

1: Calendar values (when reading from RTC\_SSR, RTC\_TR, and RTC\_DR) are taken directly from the calendar counters.

*Note: If the frequency of the APB clock is less than seven times the frequency of RTCCLK, BYPSHAD must be set to '1'.*

Bit 4 **REFCKON**: RTC\_REFIN reference clock detection enable (50 or 60 Hz)

0: RTC\_REFIN detection disabled

1: RTC\_REFIN detection enabled

*Note: PREDIV\_S must be 0x00FF.*

Bit 3 **TSEDGE**: Time-stamp event active edge

0: RTC\_TS input rising edge generates a time-stamp event

1: RTC\_TS input falling edge generates a time-stamp event

TSE must be reset when TSEDGE is changed to avoid unwanted TSF setting.

Bits 2:0 **WUCKSEL[2:0]**: Wake-up clock selection

000: RTC/16 clock is selected

001: RTC/8 clock is selected

010: RTC/4 clock is selected

011: RTC/2 clock is selected

10x: ck\_spre (usually 1 Hz) clock is selected

11x: ck\_spre (usually 1 Hz) clock is selected and  $2^{16}$  is added to the WUT counter value (see note below)

*Note: Bits 7, 6 and 4 of this register can be written in initialization mode only (RTC\_ISR/INITF = 1).*

*WUT = Wake-up unit counter value.  $WUT = (0x0000 \text{ to } 0xFFFF) + 0x10000$  added when  $WUCKSEL[2:1] = 11$ .*

*Bits 2 to 0 of this register can be written only when RTC\_CR WUTE bit = 0 and RTC\_ISR WUTWF bit = 1.*

*It is recommended not to change the hour during the calendar hour increment as it could mask the incrementation of the calendar hour.*

*ADD1H and SUB1H changes are effective in the next second.*

*This register is write protected. The write access procedure is described in [RTC register write protection on page 1218](#).*

**Caution:** TSE must be reset when TSEDGE is changed to avoid spuriously setting of TSF.

### 38.6.4 RTC initialization and status register (RTC\_ISR)

Address offset: 0x0C

Backup domain reset value: 0x0000 0007

System reset: not affected except INIT, INITF, and RSF bits which are cleared to '0'

|        |        |        |       |       |       |       |       |      |       |       |       |      |       |            |         |
|--------|--------|--------|-------|-------|-------|-------|-------|------|-------|-------|-------|------|-------|------------|---------|

| rc_w0  | rc_w0  | rc_w0  | rc_w0 | rc_w0 | rc_w0 | rc_w0 | rc_w0 | rw   | r     | rc_w0 | r     | r    | r     | r          | r       |

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **ITSF**: Internal tTime-stamp flag

This flag is set by hardware when a time-stamp on the internal event occurs.

This flag is cleared by software by writing 0, and must be cleared together with TSF bit by writing 0 in both bits.

Bit 16 **RECALPF**: Recalibration pending Flag

The RECALPF status flag is automatically set to '1' when software writes to the RTC\_CALR register, indicating that the RTC\_CALR register is blocked. When the new calibration settings are taken into account, this bit returns to '0'. Refer to [Re-calibration on-the-fly](#).

Bit 15 **TAMP3F**: RTC\_TAMP3 detection flag

This flag is set by hardware when a tamper detection event is detected on the RTC\_TAMP3 input.

It is cleared by software writing 0

Bit 14 **TAMP2F**: RTC\_TAMP2 detection flag

This flag is set by hardware when a tamper detection event is detected on the RTC\_TAMP2 input.

It is cleared by software writing 0

Bit 13 **TAMP1F**: RTC\_TAMP1 detection flag

This flag is set by hardware when a tamper detection event is detected on the RTC\_TAMP1 input.

It is cleared by software writing 0

Bit 12 **TSOVF**: Time-stamp overflow flag

This flag is set by hardware when a time-stamp event occurs while TSF is already set.

This flag is cleared by software by writing 0. It is recommended to check and then clear TSOVF only after clearing the TSF bit. Otherwise, an overflow might not be noticed if a time-stamp event occurs immediately before the TSF bit is cleared.

Bit 11 **TSF**: Time-stamp flag

This flag is set by hardware when a time-stamp event occurs.

This flag is cleared by software by writing 0. If ITSF flag is set, TSF must be cleared together with ITSF by writing 0 in both bits.

Bit 10 **WUTF**: Wake-up timer flag

This flag is set by hardware when the wake-up auto-reload counter reaches 0.

This flag is cleared by software by writing 0.

This flag must be cleared by software at least 1.5 RTCCLK periods before WUTF is set to 1 again.

Bit 9 **ALRBF**: Alarm B flag

This flag is set by hardware when the time/date registers (RTC\_TR and RTC\_DR) match the Alarm B register (RTC\_ALRMBR).

This flag is cleared by software by writing 0.

Bit 8 **ALRAF**: Alarm A flag

This flag is set by hardware when the time/date registers (RTC\_TR and RTC\_DR) match the Alarm A register (RTC\_ALRMAR).

This flag is cleared by software by writing 0.

Bit 7 **INIT**: Initialization mode

0: Free running mode

1: Initialization mode used to program time and date register (RTC\_TR and RTC\_DR), and prescaler register (RTC\_PRER). Counters are stopped and start counting from the new value when INIT is reset.

*Note: This bit is write protected. The write access procedure is described in [RTC register write protection on page 1218](#).*

Bit 6 **INITF**: Initialization flag

When this bit is set to 1, the RTC is in initialization state, and the time, date and prescaler registers can be updated.

0: Calendar registers update is not allowed

1: Calendar registers update is allowed

Bit 5 **RSF**: Registers synchronization flag

This bit is set by hardware each time the calendar registers are copied into the shadow registers (RTC\_SSR, RTC\_TR and RTC\_DR). This bit is cleared by hardware in initialization mode, while a shift operation is pending (SHPF=1), or when in bypass shadow register mode (BYPSSHAD=1). This bit can also be cleared by software.

It is cleared either by software or by hardware in initialization mode.

0: Calendar shadow registers not yet synchronized

1: Calendar shadow registers synchronized

*Note: This bit is write protected. The write access procedure is described in [RTC register write protection on page 1218](#).*

Bit 4 **INITS**: Initialization status flag

This bit is set by hardware when the calendar year field is different from 0 (Backup domain reset state).

0: Calendar has not been initialized

1: Calendar has been initialized

Bit 3 **SHPF**: Shift operation pending

0: No shift operation is pending

1: A shift operation is pending

This flag is set by hardware as soon as a shift operation is initiated by a write to the RTC\_SHIFTR register. It is cleared by hardware when the corresponding shift operation has been executed. Writing to the SHPF bit has no effect.

**Bit 2 WUTWF:** Wake-up timer write flag

This bit is set by hardware up to 2 RTCCLK cycles after the WUTE bit has been set to 0 in RTC\_CR, and is cleared up to 2 RTCCLK cycles after the WUTE bit has been set to 1. The wake-up timer values can be changed when WUTE bit is cleared and WUTWF is set.

0: Wake-up timer configuration update not allowed

1: Wake-up timer configuration update allowed

**Bit 1 ALRBWF:** Alarm B write flag

This bit is set by hardware when Alarm B values can be changed, after the ALRBE bit has been set to 0 in RTC\_CR.

It is cleared by hardware in initialization mode.

0: Alarm B update not allowed

1: Alarm B update allowed

**Bit 0 ALRAWF:** Alarm A write flag

This bit is set by hardware when Alarm A values can be changed, after the ALRAE bit has been set to 0 in RTC\_CR.

It is cleared by hardware in initialization mode.

0: Alarm A update not allowed

1: Alarm A update allowed

**Note:** *The bits ALRAF, ALRBF, WUTF and TSF are cleared 2 APB clock cycles after programming them to 0.*

### 38.6.5 RTC prescaler register (RTC\_PRER)

This register must be written in initialization mode only. The initialization must be performed in two separate write accesses. Refer to [Calendar initialization and configuration on page 1219](#).

This register is write protected. The write access procedure is described in [RTC register write protection on page 1218](#).

Address offset: 0x10

Backup domain reset value: 0x007F 00FF

System reset: not affected

|      |                |      |      |      |      |      |      |      |               |    |    |    |    |    |    |
|------|----------------|------|------|------|------|------|------|------|---------------|----|----|----|----|----|----|
| 31   | 30             | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22            | 21 | 20 | 19 | 18 | 17 | 16 |

| Res. | PREDIV_S[14:0] |      |      |      |      |      |      |      |               |    |    |    |    |    |    |
|      | rw             | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw            | rw | rw | rw | rw | rw | rw |

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:16 **PREDIV\_A[6:0]**: Asynchronous prescaler factor

This is the asynchronous division factor:

$ck\_apre\ frequency = RTCCLK\ frequency / (PREDIV\_A + 1)$

Bit 15 Reserved, must be kept at reset value.

Bits 14:0 **PREDIV\_S[14:0]**: Synchronous prescaler factor

This is the synchronous division factor:

$ck\_spre\ frequency = ck\_apre\ frequency / (PREDIV\_S + 1)$

### 38.6.6 RTC wake-up timer register (RTC\_WUTR)

This register can be written only when WUTWF is set to 1 in RTC\_ISR.

This register is write protected. The write access procedure is described in [RTC register write protection on page 1218](#).

Address offset: 0x14

Backup domain reset value: 0x0000 FFFF

System reset: not affected

|           |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|-----------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| 31        | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Res.      | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. |
|           |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| 15        | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| WUT[15:0] |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| rw        | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **WUT[15:0]**: Wake-up auto-reload value bits

When the wake-up timer is enabled (WUTE set to 1), the WUTF flag is set every (WUT[15:0] + 1) ck\_wut cycles. The ck\_wut period is selected through WUCKSEL[2:0] bits of the RTC\_CR register

When WUCKSEL[2] = 1, the wake-up timer becomes 17-bits and WUCKSEL[1] effectively becomes WUT[16] the most-significant bit to be reloaded into the timer.

The first assertion of WUTF occurs (WUT+1) ck\_wut cycles after WUTE is set. Setting WUT[15:0] to 0x0000 with WUCKSEL[2:0] = 011 (RTCCLK/2) is forbidden.

### 38.6.7 RTC alarm A register (RTC\_ALRMAR)

This register can be written only when ALRAWF is set to 1 in RTC\_ISR, or in initialization mode.

This register is write protected. The write access procedure is described in [RTC register write protection on page 1218](#).

Address offset: 0x1C

Backup domain reset value: 0x0000 0000

System reset: not affected

|      |          |         |    |          |    |    |    |      |         |         |    |         |    |    |    |

Bit 31 **MSK4**: Alarm A date mask

- 0: Alarm A set if the date/day match
- 1: Date/day don't care in Alarm A comparison

Bit 30 **WDSEL**: Week day selection

- 0: DU[3:0] represents the date units
- 1: DU[3:0] represents the week day. DT[1:0] is don't care.

Bits 29:28 **DT[1:0]**: Date tens in BCD format.

Bits 27:24 **DU[3:0]**: Date units or day in BCD format.

Bit 23 **MSK3**: Alarm A hours mask

- 0: Alarm A set if the hours match
- 1: Hours don't care in Alarm A comparison

Bit 22 **PM**: AM/PM notation

- 0: AM or 24-hour format
- 1: PM

Bits 21:20 **HT[1:0]**: Hour tens in BCD format.

Bits 19:16 **HU[3:0]**: Hour units in BCD format.

Bit 15 **MSK2**: Alarm A minutes mask

- 0: Alarm A set if the minutes match
- 1: Minutes don't care in Alarm A comparison

Bits 14:12 **MNT[2:0]**: Minute tens in BCD format.

Bits 11:8 **MNU[3:0]**: Minute units in BCD format.

Bit 7 **MSK1**: Alarm A seconds mask

- 0: Alarm A set if the seconds match
- 1: Seconds don't care in Alarm A comparison

Bits 6:4 **ST[2:0]**: Second tens in BCD format.

Bits 3:0 **SU[3:0]**: Second units in BCD format.

### 38.6.8 RTC alarm B register (RTC\_ALRMBR)

This register can be written only when ALRBWF is set to 1 in RTC\_ISR, or in initialization mode.

This register is write protected. The write access procedure is described in [RTC register write protection on page 1218](#).

Address offset: 0x20

Backup domain reset value: 0x0000 0000

System reset: not affected

|      |          |         |    |          |    |    |    |      |         |         |    |         |    |    |    |

Bit 31 **MSK4**: Alarm B date mask

0: Alarm B set if the date and day match

1: Date and day don't care in Alarm B comparison

Bit 30 **WDSEL**: Week day selection

0: DU[3:0] represents the date units

1: DU[3:0] represents the week day. DT[1:0] is don't care.

Bits 29:28 **DT[1:0]**: Date tens in BCD format

Bits 27:24 **DU[3:0]**: Date units or day in BCD format

Bit 23 **MSK3**: Alarm B hours mask

0: Alarm B set if the hours match

1: Hours don't care in Alarm B comparison

Bit 22 **PM**: AM/PM notation

0: AM or 24-hour format

1: PM

Bits 21:20 **HT[1:0]**: Hour tens in BCD format

Bits 19:16 **HU[3:0]**: Hour units in BCD format

Bit 15 **MSK2**: Alarm B minutes mask

0: Alarm B set if the minutes match

1: Minutes don't care in Alarm B comparison

Bits 14:12 **MNT[2:0]**: Minute tens in BCD format

Bits 11:8 **MNU[3:0]**: Minute units in BCD format

Bit 7 **MSK1**: Alarm B seconds mask

0: Alarm B set if the seconds match

1: Seconds don't care in Alarm B comparison

Bits 6:4 **ST[2:0]**: Second tens in BCD format

Bits 3:0 **SU[3:0]**: Second units in BCD format

### 38.6.9 RTC write protection register (RTC\_WPR)

Address offset: 0x24

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |          |      |      |      |      |      |      |      |
|------|------|------|------|------|------|------|------|----------|------|------|------|------|------|------|------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23       | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.     | Res. | Res. | Res. | Res. | Res. | Res. | Res. |
|      |      |      |      |      |      |      |      |          |      |      |      |      |      |      |      |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7        | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | KEY[7:0] |      |      |      |      |      |      |      |
|      |      |      |      |      |      |      |      | w        | w    | w    | w    | w    | w    | w    | w    |

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **KEY[7:0]**: Write protection key

This byte is written by software.

Reading this byte always returns 0x00.

Refer to [RTC register write protection](#) for a description of how to unlock RTC register write protection.

### 38.6.10 RTC sub second register (RTC\_SSR)

Address offset: 0x28

Backup domain reset value: 0x0000 0000

System reset: 0x0000 0000 when BYPSHAD = 0. Not affected when BYPSHAD = 1.

|          |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|----------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| 31       | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Res.     | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. |
|          |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| 15       | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| SS[15:0] |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| r        | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **SS[15:0]**: Sub second value

SS[15:0] is the value in the synchronous prescaler counter. The fraction of a second is given by the formula below:

Second fraction = (PREDIV\_S - SS) / (PREDIV\_S + 1)

*Note: SS can be larger than PREDIV\_S only after a shift operation. In that case, the correct time/date is one second less than as indicated by RTC\_TR/RTC\_DR.*

### 38.6.11 RTC shift control register (RTC\_SHIFTR)

This register is write protected. The write access procedure is described in [RTC register write protection on page 1218](#).

Address offset: 0x2C

Backup domain reset value: 0x0000 0000

System reset: not affected

| 31    | 30          | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
|-------|-------------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| ADD1S | Res.        | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. |
| w     |             |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| 15    | 14          | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| Res.  | SUBFS[14:0] |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|       | w           | w    | w    | w    | w    | w    | w    | w    | w    | w    | w    | w    | w    | w    | w    |

Bit 31 **ADD1S**: Add one second

0: No effect

1: Add one second to the clock/calendar

This bit is write only and is always read as zero. Writing to this bit has no effect when a shift operation is pending (when SHPF=1, in RTC\_ISR).

This function is intended to be used with SUBFS (see description below) in order to effectively add a fraction of a second to the clock in an atomic operation.

Bits 30:15 Reserved, must be kept at reset value.

Bits 14:0 **SUBFS[14:0]**: Subtract a fraction of a second

These bits are write only and is always read as zero. Writing to this bit has no effect when a shift operation is pending (when SHPF=1, in RTC\_ISR).

The value which is written to SUBFS is added to the synchronous prescaler counter. Since this counter counts down, this operation effectively subtracts from (delays) the clock by:

Delay (seconds) = SUBFS / (PREDIV\_S + 1)

A fraction of a second can effectively be added to the clock (advancing the clock) when the ADD1S function is used in conjunction with SUBFS, effectively advancing the clock by:

Advance (seconds) = (1 - (SUBFS / (PREDIV\_S + 1))).

*Note: Writing to SUBFS causes RSF to be cleared. Software can then wait until RSF=1 to be sure that the shadow registers have been updated with the shifted time.*

### 38.6.12 RTC timestamp time register (RTC\_TSTR)

The content of this register is valid only when TSF is set to 1 in RTC\_ISR. It is cleared when TSF bit is reset.

Address offset: 0x30

Backup domain reset value: 0x0000 0000

System reset: not affected

|      |          |      |      |          |      |      |      |      |         |         |    |         |    |    |    |
|------|----------|------|------|----------|------|------|------|------|---------|---------|----|---------|----|----|----|
| 31   | 30       | 29   | 28   | 27       | 26   | 25   | 24   | 23   | 22      | 21      | 20 | 19      | 18 | 17 | 16 |
| Res. | Res.     | Res. | Res. | Res.     | Res. | Res. | Res. | Res. | PM      | HT[1:0] |    | HU[3:0] |    |    |    |

| 15   | 14       | 13   | 12   | 11       | 10   | 9    | 8    | 7    | 6       | 5       | 4  | 3       | 2  | 1  | 0  |
| Res. | MNT[2:0] |      |      | MNU[3:0] |      |      |      | Res. | ST[2:0] |         |    | SU[3:0] |    |    |    |
|      | r        | r    | r    | r        | r    | r    | r    |      | r       | r       | r  | r       | r  | r  | r  |

Bits 31:23 Reserved, must be kept at reset value.

Bit 22 **PM**: AM/PM notation

0: AM or 24-hour format

1: PM

Bits 21:20 **HT[1:0]**: Hour tens in BCD format.

Bits 19:16 **HU[3:0]**: Hour units in BCD format.

Bit 15 Reserved, must be kept at reset value.

Bits 14:12 **MNT[2:0]**: Minute tens in BCD format.

Bits 11:8 **MNU[3:0]**: Minute units in BCD format.

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **ST[2:0]**: Second tens in BCD format.

Bits 3:0 **SU[3:0]**: Second units in BCD format.

### 38.6.13 RTC timestamp date register (RTC\_TSDR)

The content of this register is valid only when TSF is set to 1 in RTC\_ISR. It is cleared when TSF bit is reset.

Address offset: 0x34

Backup domain reset value: 0x0000 0000

System reset: not affected

|          |      |      |      |         |      |      |      |      |      |         |      |         |      |      |      |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:13 **WDU[2:0]**: Week day units

Bit 12 **MT**: Month tens in BCD format

Bits 11:8 **MU[3:0]**: Month units in BCD format

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **DT[1:0]**: Date tens in BCD format

Bits 3:0 **DU[3:0]**: Date units in BCD format

38.6.14 RTC time-stamp sub second register (RTC\_TSSSR)

The content of this register is valid only when RTC\_ISR/TSF is set. It is cleared when the RTC\_ISR/TSF bit is reset.

Address offset: 0x38

Backup domain reset value: 0x0000 0000

System reset: not affected

|          |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|----------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| 31       | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |

|          |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| 15       | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| SS[15:0] |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| r        | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **SS[15:0]**: Sub second value

SS[15:0] is the value of the synchronous prescaler counter when the timestamp event occurred.

### 38.6.15 RTC calibration register (RTC\_CALR)

This register is write protected. The write access procedure is described in [RTC register write protection on page 1218](#).

Address offset: 0x3C

Backup domain reset value: 0x0000 0000

System reset: not affected

|      |       |        |      |      |      |      |           |      |      |      |      |      |      |      |      |

|      |       |        |      |      |      |      |           |      |      |      |      |      |      |      |      |
| 15   | 14    | 13     | 12   | 11   | 10   | 9    | 8         | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| CALP | CALW8 | CALW16 | Res. | Res. | Res. | Res. | CALM[8:0] |      |      |      |      |      |      |      |      |
| rw   | rw    | rw     |      |      |      |      | rw        | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   |

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **CALP**: Increase frequency of RTC by 488.5 ppm

0: No RTCCLK pulses are added.

1: One RTCCLK pulse is effectively inserted every  $2^{11}$  pulses (frequency increased by 488.5 ppm).

This feature is intended to be used in conjunction with CALM, which lowers the frequency of the calendar with a fine resolution. If the input frequency is 32768 Hz, the number of RTCCLK pulses added during a 32-second window is calculated as follows:  $(512 * CALP) - CALM$ .

Refer to [Section 38.3.12: RTC smooth digital calibration](#).

Bit 14 **CALW8**: Use an 8-second calibration cycle period

When CALW8 is set to '1', the 8-second calibration cycle period is selected.

*Note: CALM[1:0] are stuck at "00" when CALW8='1'. Refer to [Section 38.3.12: RTC smooth digital calibration](#).*

Bit 13 **CALW16**: Use a 16-second calibration cycle period

When CALW16 is set to '1', the 16-second calibration cycle period is selected. This bit must not be set to '1' if CALW8=1.

*Note: CALM[0] is stuck at '0' when CALW16='1'. Refer to [Section 38.3.12: RTC smooth digital calibration](#).*

Bits 12:9 Reserved, must be kept at reset value.

Bits 8:0 **CALM[8:0]**: Calibration minus

The frequency of the calendar is reduced by masking CALM out of  $2^{20}$  RTCCLK pulses (32 seconds if the input frequency is 32768 Hz). This decreases the frequency of the calendar with a resolution of 0.9537 ppm.

To increase the frequency of the calendar, this feature should be used in conjunction with CALP. See [Section 38.3.12: RTC smooth digital calibration on page 1222](#).

### 38.6.16 RTC tamper configuration register (RTC\_TAMPCR)

Address offset: 0x40

Backup domain reset value: 0x0000 0000

System reset: not affected

|            |                |      |              |      |               |      |          |                |           |          |                |          |          |                |          |

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **TAMP3MF**: Tamper 3 mask flag

0: Tamper 3 event generates a trigger event and TAMP3F must be cleared by software to allow next tamper event detection.

1: Tamper 3 event generates a trigger event. TAMP3F is masked and internally cleared by hardware. The backup registers are not erased.

*Note: The Tamper 3 interrupt must not be enabled when TAMP3MF is set.*

Bit 23 **TAMP3NOERASE**: Tamper 3 no erase

0: Tamper 3 event erases the backup registers.

1: Tamper 3 event does not erase the backup registers.

Bit 22 **TAMP3IE**: Tamper 3 interrupt enable

0: Tamper 3 interrupt is disabled if TAMPIE = 0.

1: Tamper 3 interrupt enabled.

Bit 21 **TAMP2MF**: Tamper 2 mask flag

0: Tamper 2 event generates a trigger event and TAMP2F must be cleared by software to allow next tamper event detection.

1: Tamper 2 event generates a trigger event. TAMP2F is masked and internally cleared by hardware. The backup registers are not erased.

*Note: The Tamper 2 interrupt must not be enabled when TAMP2MF is set.*

Bit 20 **TAMP2NOERASE**: Tamper 2 no erase

0: Tamper 2 event erases the backup registers.

1: Tamper 2 event does not erase the backup registers.

Bit 19 **TAMP2IE**: Tamper 2 interrupt enable

0: Tamper 2 interrupt is disabled if TAMPIE = 0.

1: Tamper 2 interrupt enabled.

Bit 18 **TAMP1MF**: Tamper 1 mask flag

0: Tamper 1 event generates a trigger event and TAMP1F must be cleared by software to allow next tamper event detection.

1: Tamper 1 event generates a trigger event. TAMP1F is masked and internally cleared by hardware. The backup registers are not erased.

*Note: The Tamper 1 interrupt must not be enabled when TAMP1MF is set.*

- Bit 17 **TAMP1NOERASE**: Tamper 1 no erase  
 0: Tamper 1 event erases the backup registers.  
 1: Tamper 1 event does not erase the backup registers.
- Bit 16 **TAMP1IE**: Tamper 1 interrupt enable  
 0: Tamper 1 interrupt is disabled if TAMPIE = 0.  
 1: Tamper 1 interrupt enabled.
- Bit 15 **TAMPPUDIS**: RTC\_TAMPx pull-up disable  
 This bit determines if each of the RTC\_TAMPx pins are precharged before each sample.  
 0: Precharge RTC\_TAMPx pins before sampling (enable internal pull-up)  
 1: Disable precharge of RTC\_TAMPx pins.
- Bits 14:13 **TAMPPRCH[1:0]**: RTC\_TAMPx precharge duration  
 These bit determines the duration of time during which the pull-up/is activated before each sample. TAMPPRCH is valid for each of the RTC\_TAMPx inputs.  
 0x0: 1 RTCCLK cycle  
 0x1: 2 RTCCLK cycles  
 0x2: 4 RTCCLK cycles  
 0x3: 8 RTCCLK cycles
- Bits 12:11 **TAMPFLT[1:0]**: RTC\_TAMPx filter count  
 These bits determines the number of consecutive samples at the specified level (TAMP\*TRG) needed to activate a Tamper event. TAMPFLT is valid for each of the RTC\_TAMPx inputs.  
 0x0: Tamper event is activated on edge of RTC\_TAMPx input transitions to the active level (no internal pull-up on RTC\_TAMPx input).  
 0x1: Tamper event is activated after 2 consecutive samples at the active level.  
 0x2: Tamper event is activated after 4 consecutive samples at the active level.  
 0x3: Tamper event is activated after 8 consecutive samples at the active level.
- Bits 10:8 **TAMPFREQ[2:0]**: Tamper sampling frequency  
 Determines the frequency at which each of the RTC\_TAMPx inputs are sampled.  
 0x0: RTCCLK / 32768 (1 Hz when RTCCLK = 32768 Hz)  
 0x1: RTCCLK / 16384 (2 Hz when RTCCLK = 32768 Hz)  
 0x2: RTCCLK / 8192 (4 Hz when RTCCLK = 32768 Hz)  
 0x3: RTCCLK / 4096 (8 Hz when RTCCLK = 32768 Hz)  
 0x4: RTCCLK / 2048 (16 Hz when RTCCLK = 32768 Hz)  
 0x5: RTCCLK / 1024 (32 Hz when RTCCLK = 32768 Hz)  
 0x6: RTCCLK / 512 (64 Hz when RTCCLK = 32768 Hz)  
 0x7: RTCCLK / 256 (128 Hz when RTCCLK = 32768 Hz)
- Bit 7 **TAMPTS**: Activate timestamp on tamper detection event  
 0: Tamper detection event does not cause a timestamp to be saved  
 1: Save timestamp on tamper detection event  
 TAMPTS is valid even if TSE=0 in the RTC\_CR register.
- Bit 6 **TAMP3TRG**: Active level for RTC\_TAMP3 input  
 if TAMPFLT ≠ 00:  
 0: RTC\_TAMP3 input staying low triggers a tamper detection event.  
 1: RTC\_TAMP3 input staying high triggers a tamper detection event.  
 if TAMPFLT = 00:  
 0: RTC\_TAMP3 input rising edge triggers a tamper detection event.  
 1: RTC\_TAMP3 input falling edge triggers a tamper detection event.

Bit 5 **TAMP3E**: RTC\_TAMP3 detection enable

0: RTC\_TAMP3 input detection disabled

1: RTC\_TAMP3 input detection enabled

Bit 4 **TAMP2TRG**: Active level for RTC\_TAMP2 input

if TAMPFLT != 00:

0: RTC\_TAMP2 input staying low triggers a tamper detection event.

1: RTC\_TAMP2 input staying high triggers a tamper detection event.

if TAMPFLT = 00:

0: RTC\_TAMP2 input rising edge triggers a tamper detection event.

1: RTC\_TAMP2 input falling edge triggers a tamper detection event.

Bit 3 **TAMP2E**: RTC\_TAMP2 input detection enable

0: RTC\_TAMP2 detection disabled

1: RTC\_TAMP2 detection enabled

Bit 2 **TAMPIE**: Tamper interrupt enable

0: Tamper interrupt disabled

1: Tamper interrupt enabled.

*Note: This bit enables the interrupt for all tamper pins events, whatever TAMPxIE level. If this bit is cleared, each tamper event interrupt can be individually enabled by setting TAMPxIE.*

Bit 1 **TAMP1TRG**: Active level for RTC\_TAMP1 input

If TAMPFLT != 00

0: RTC\_TAMP1 input staying low triggers a tamper detection event.

1: RTC\_TAMP1 input staying high triggers a tamper detection event.

if TAMPFLT = 00:

0: RTC\_TAMP1 input rising edge triggers a tamper detection event.

1: RTC\_TAMP1 input falling edge triggers a tamper detection event.

Bit 0 **TAMP1E**: RTC\_TAMP1 input detection enable

0: RTC\_TAMP1 detection disabled

1: RTC\_TAMP1 detection enabled

**Caution:** When TAMPFLT = 0, TAMPxE must be reset when TAMPxTRG is changed to avoid spuriously setting TAMPxF.

### 38.6.17 RTC alarm A sub second register (RTC\_ALRMASSR)

This register can be written only when ALRAE is reset in RTC\_CR register, or in initialization mode.

This register is write protected. The write access procedure is described in [RTC register write protection on page 1218](#)

Address offset: 0x44

Backup domain reset value: 0x0000 0000

System reset: not affected

|      |          |      |      |             |    |    |    |      |      |      |      |      |      |      |      |

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:24 MASKSS[3:0]: Mask the most-significant bits starting at this bit

0: No comparison on sub seconds for Alarm A. The alarm is set when the seconds unit is incremented (assuming that the rest of the fields match).

1: SS[14:1] are don't care in Alarm A comparison. Only SS[0] is compared.

2: SS[14:2] are don't care in Alarm A comparison. Only SS[1:0] are compared.

3: SS[14:3] are don't care in Alarm A comparison. Only SS[2:0] are compared.

...

12: SS[14:12] are don't care in Alarm A comparison. SS[11:0] are compared.

13: SS[14:13] are don't care in Alarm A comparison. SS[12:0] are compared.

14: SS[14] is don't care in Alarm A comparison. SS[13:0] are compared.

15: All 15 SS bits are compared and must match to activate alarm.

The overflow bits of the synchronous counter (bits 15) is never compared. This bit can be different from 0 only after a shift operation.

Bits 23:15 Reserved, must be kept at reset value.

Bits 14:0 SS[14:0]: Sub seconds value

This value is compared with the contents of the synchronous prescaler counter to determine if Alarm A is to be activated. Only bits 0 up MASKSS-1 are compared.

### 38.6.18 RTC alarm B sub second register (RTC\_ALRMBSSR)

This register can be written only when ALRBE is reset in RTC\_CR register, or in initialization mode.

This register is write protected. The write access procedure is described in [Section : RTC register write protection](#).

Address offset: 0x48

Backup domain reset value: 0x0000 0000

System reset: not affected

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:24 **MASKSS[3:0]**: Mask the most-significant bits starting at this bit

0x0: No comparison on sub seconds for Alarm B. The alarm is set when the seconds unit is incremented (assuming that the rest of the fields match).

0x1: SS[14:1] are don't care in Alarm B comparison. Only SS[0] is compared.

0x2: SS[14:2] are don't care in Alarm B comparison. Only SS[1:0] are compared.

0x3: SS[14:3] are don't care in Alarm B comparison. Only SS[2:0] are compared.

...

0xC: SS[14:12] are don't care in Alarm B comparison. SS[11:0] are compared.

0xD: SS[14:13] are don't care in Alarm B comparison. SS[12:0] are compared.

0xE: SS[14] is don't care in Alarm B comparison. SS[13:0] are compared.

0xF: All 15 SS bits are compared and must match to activate alarm.

The overflow bits of the synchronous counter (bits 15) is never compared. This bit can be different from 0 only after a shift operation.

Bits 23:15 Reserved, must be kept at reset value.

Bits 14:0 **SS[14:0]**: Sub seconds value

This value is compared with the contents of the synchronous prescaler counter to determine if Alarm B is to be activated. Only bits 0 up to MASKSS-1 are compared.

### 38.6.19 RTC option register (RTC\_OR)

Address offset: 0x4C

Backup domain reset value: 0x0000 0000

System reset: not affected

|      |      |      |      |      |      |      |      |      |      |      |      |      |      |             |                |
|------|------|------|------|------|------|------|------|------|------|------|------|------|------|-------------|----------------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17          | 16             |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.        | Res.           |
|      |      |      |      |      |      |      |      |      |      |      |      |      |      |             |                |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1           | 0              |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | RTC_OUT_RMP | RTC_ALARM_TYPE |
|      |      |      |      |      |      |      |      |      |      |      |      |      |      | rw          | rw             |

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **RTC\_OUT\_RMP**: RTC\_OUT remap

Setting this bit allows to remap the RTC outputs on PB2 as follows:

**RTC\_OUT\_RMP = '0':**

If OSEL /= '00': RTC\_ALARM is output on PC13

If OSEL = '00' and COE = '1': RTC\_CALIB is output on PC13

**RTC\_OUT\_RMP = '1':**

If OSEL /= '00' and COE = '0': RTC\_ALARM is output on PB2

If OSEL = '00' and COE = '1': RTC\_CALIB is output on PB2

If OSEL /= '00' and COE = '1': RTC\_CALIB is output on PB2 and RTC\_ALARM is output on PC13.

Bit 0 **RTC\_ALARM\_TYPE**: RTC\_ALARM output type on PC13

This bit is set and cleared by software

0: RTC\_ALARM, when mapped on PC13, is open-drain output

1: RTC\_ALARM, when mapped on PC13, is push-pull output

### 38.6.20 RTC backup registers (RTC\_BKPxR)

Address offset: 0x50 to 0xCC

Backup domain reset value: 0x0000 0000

System reset: not affected

|            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

Bits 31:0 BKP[31:0]

The application can write or read data to and from these registers.

They are powered-on by V<sub>BAT</sub> when V<sub>DD</sub> is switched off, so that they are not reset by

System reset, and their contents remain valid when the device operates in low-power mode.

This register is reset on a tamper detection event, as long as TAMPx F=1.

## 38.6.21 RTC register map

Table 227. RTC register map and reset values

| Offset | Register name | 31    | 30    | 29      | 28   | 27   | 26   | 25      | 24   | 23      | 22            | 21      | 20      | 19      | 18   | 17    | 16       | 15             | 14          | 13     | 12     | 11      | 10       | 9     | 8     | 7    | 6        | 5       | 4       | 3       | 2            | 1       | 0      |   |         |  |  |  |  |  |

Refer to [Section 2.2 on page 75](#) for the register boundary addresses.

## 39 Inter-integrated circuit (I2C) interface

### 39.1 Introduction

The I2C peripheral handles the interface between the device and the serial I<sup>2</sup>C (inter-integrated circuit) bus. It provides multimaster capability, and controls all I<sup>2</sup>C-bus-specific sequencing, protocol, arbitration and timing. It supports Standard-mode (Sm), Fast-mode (Fm) and Fast-mode Plus (Fm+).

The I2C peripheral is also SMBus (system management bus) and PMBus<sup>®</sup> (power management bus) compatible.

It can use DMA to reduce the CPU load.

### 39.2 I2C main features

- I<sup>2</sup>C-bus specification rev03 compatibility:
  - Slave and master modes
  - Multimaster capability
  - Standard-mode (up to 100 kHz)
  - Fast-mode (up to 400 kHz)
  - Fast-mode Plus (up to 1 MHz)
  - 7-bit and 10-bit addressing mode
  - Multiple 7-bit slave addresses (2 addresses, 1 with configurable mask)
  - All 7-bit-addresses acknowledge mode
  - General call
  - Programmable setup and hold times
  - Easy-to-use event management
  - Clock stretching (optional)
- 1-byte buffer with DMA capability
- Programmable analog and digital noise filters
- SMBus specification rev 3.0 compatibility:
  - Hardware PEC (packet error checking) generation and verification with ACK control
  - Command and data acknowledge control
  - Address resolution protocol (ARP) support
  - Host and device support
  - SMBus alert
  - Timeouts and idle condition detection
- PMBus rev 1.3 standard compatibility
- Independent clock
- Wake-up from Stop mode on address match

For information on I2C instantiation, refer to [Section 39.3: I2C implementation](#).

### 39.3 I2C implementation

This section provides an implementation overview with respect to the I2C instantiation.

**Table 228. STM32L47x/L48x I2C implementation**

| I2C features <sup>(1)</sup>                                  | I2C1 | I2C2 | I2C3 |
|--------------------------------------------------------------|------|------|------|
| 7-bit addressing mode                                        | X    | X    | X    |
| 10-bit addressing mode                                       | X    | X    | X    |
| Standard-mode (up to 100 kbit/s)                             | X    | X    | X    |
| Fast-mode (up to 400 kbit/s)                                 | X    | X    | X    |
| Fast-mode Plus with 20 mA output drive I/Os (up to 1 Mbit/s) | X    | X    | X    |
| Independent clock                                            | X    | X    | X    |
| Wake-up from Stop 0 mode                                     | X    | X    | X    |
| Wake-up from Stop 1 mode                                     | X    | X    | X    |
| Wake-up from Stop 2 mode                                     | -    | -    | X    |
| SMBus/PMBus                                                  | X    | X    | X    |

1. X = supported.

**Table 229. STM32L49x/L4Ax I2C implementation**

| I2C features <sup>(1)</sup>                                  | I2C1 | I2C2 | I2C3 | I2C4 |
|--------------------------------------------------------------|------|------|------|------|
| 7-bit addressing mode                                        | X    | X    | X    | X    |
| 10-bit addressing mode                                       | X    | X    | X    | X    |
| Standard-mode (up to 100 kbit/s)                             | X    | X    | X    | X    |
| Fast-mode (up to 400 kbit/s)                                 | X    | X    | X    | X    |
| Fast-mode Plus with 20 mA output drive I/Os (up to 1 Mbit/s) | X    | X    | X    | X    |
| Independent clock                                            | X    | X    | X    | X    |
| Wake-up from Stop 1 mode                                     | X    | X    | X    | X    |
| Wake-up from Stop 2 mode                                     | -    | -    | X    | -    |
| SMBus/PMBus                                                  | X    | X    | X    | X    |

1. X = supported.

### 39.4 I2C functional description

In addition to receiving and transmitting data, the peripheral converts them from serial to parallel format and vice versa. The interrupts are enabled or disabled by software. The peripheral is connected to the I<sup>2</sup>C-bus through a data pin (SDA) and a clock pin (SCL). It supports Standard-mode (up to 100 kHz), Fast-mode (up to 400 kHz), and Fast-mode Plus (up to 1 MHz) I<sup>2</sup>C-bus.

The peripheral can also be connected to an SMBus, through the data pin (SDA), the clock pin (SCL), and an optional SMBus alert pin (SMBA).

The independent clock function allows the I2C communication speed to be independent of the PCLK1 frequency.

For I2C I/Os supporting 20 mA output current drive for Fast-mode Plus operation, the driving capability is enabled through control bits in the system configuration controller (SYSCFG).

| i2c_tx_dma           | Output      | I2C transmit data DMA request (I2C_TX)                                               |

### 39.4.3 I2C clock requirements

The I2C kernel is clocked by I2CCLK.

The I2CCLK period  $t_{I2CCLK}$  must respect the following conditions:

$$t_{I2CCLK} < (t_{LOW} - t_{filters}) / 4$$

$$t_{I2CCLK} < t_{HIGH}$$

where  $t_{LOW}$  is the SCL low time,  $t_{HIGH}$  is the SCL high time, and  $t_{filters}$  is the sum of the analog and digital filter delays (when enabled).

The digital filter delay is  $DNF[3:0] \times t_{I2CCLK}$ .

The PCLK1 clock period  $t_{PCLK}$  must respect the condition  $t_{PCLK} < 4/3 t_{SCL}$ , where  $t_{SCL}$  is the SCL period.

**Caution:** When the I2C kernel is clocked by PCLK1, this clock must respect the conditions for  $t_{I2CCLK}$ .

### 39.4.4 Mode selection

The peripheral can operate as:

- slave transmitter
- slave receiver
- master transmitter
- master receiver

By default, the peripheral operates in slave mode. It automatically switches from slave to master mode upon generating START condition, and from master to slave mode upon arbitration loss or upon generating STOP condition. This allows the use of the I2C peripheral in a multimaster I<sup>2</sup>C-bus environment.

### Communication flow

In master mode, the I2C peripheral initiates a data transfer and generates the clock signal. Serial data transfers always begin with a START condition and end with a STOP condition. Both START and STOP conditions are generated in master mode by software.

In slave mode, the peripheral recognizes its own 7-bit or 10-bit address, and the general call address. The general call address detection can be enabled or disabled by software. The reserved SMBus addresses can also be enabled by software.

Data and addresses are transferred as 8-bit bytes, MSB first. The first one (7-bit addressing) or two (10-bit addressing) bytes following the START condition contain the address. The address is always transmitted in master mode.

The following figure shows the transmission of a single byte. The master generates nine SCL pulses. The transmitter sends the eight data bits to the receiver with the SCL pulses 1 to 8. Then the receiver sends the acknowledge bit to the transmitter with the ninth SCL pulse.

**Figure 391. I<sup>2</sup>C-bus protocol**

The acknowledge can be enabled or disabled by software. The own addresses of the I2C peripheral can be selected by software.

## 39.4.5 I2C initialization

### Enabling and disabling the peripheral

Before enabling the I2C peripheral, configure and enable its clock through the clock controller, and initialize its control registers.

The I2C peripheral can then be enabled by setting the PE bit of the I2C\_CR1 register.

Disabling the I2C peripheral by clearing the PE bit resets the I2C peripheral. Refer to [Section 39.4.6](#) for more details.

### Noise filters

Before enabling the I2C peripheral by setting the PE bit of the I2C\_CR1 register, the user must configure the analog and/or digital noise filters, as required.

The analog noise filter on the SDA and SCL inputs complies with the I<sup>2</sup>C-bus specification which requires, in Fast-mode and Fast-mode Plus, the suppression of spikes shorter than 50 ns. Enabled by default, it can be disabled by setting the ANFOFF bit.

The digital filter is controlled through the DNF[3:0] bitfield of the I2C\_CR1 register. When it is enabled, the internal SCL and SDA signals only take the level of their corresponding I<sup>2</sup>C-bus line when remaining stable for more than DNF[3:0] periods of I2CCLK. This allows suppressing spikes shorter than the filtering capacity period programmable from one to fifteen I2CCLK periods.

The following table compares the two filters.

**Table 232. Comparison of analog and digital filters**

| Item                              | Analog filter                                                               | Digital filter                                                                                                                                                                                                      |
|-----------------------------------|-----------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Filtering capacity <sup>(1)</sup> | ≥ 50 ns                                                                     | One to fifteen I2CCLK periods                                                                                                                                                                                       |
| Benefits                          | Available in Stop mode                                                      | <ul style="list-style-type: none"> <li>– Programmable filtering capacity</li> <li>– Extra filtering capability versus I<sup>2</sup>C-bus specification requirements</li> <li>– Stable filtering capacity</li> </ul> |
| Drawbacks                         | Filtering capacity variation with temperature, voltage, and silicon process | Wake-up from Stop mode on address match not supported when the digital filter is enabled                                                                                                                            |

1. Maximum duration of spikes that the filter can suppress

**Caution:** The filter configuration cannot be changed when the I2C peripheral is enabled.

### I2C timings

To ensure correct data hold and setup times, the corresponding timings must be configured through the PRESC[3:0], SCLDEL[3:0], and SDADEL[3:0] bitfields of the I2C\_TIMINGR register.

The STM32CubeMX tool calculates and provides the I2C\_TIMINGR content in the *I2C configuration* window.

Figure 392. Setup and hold timings

When the SCL falling edge is internally detected, the delay  $t_{\text{SDADEL}}$  (impacting the hold time  $t_{\text{HD,DAT}}$ ) is inserted before sending SDA output:

$$t_{\text{SDADEL}} = \text{SDADEL} \times t_{\text{PRESC}} + t_{\text{I2CCLK}}, \text{ where } t_{\text{PRESC}} = (\text{PRESC} + 1) \times t_{\text{I2CCLK}}.$$

The total SDA output delay is:

$$t_{\text{SYNC1}} + \{[\text{SDADEL} \times (\text{PRESC} + 1) + 1] \times t_{\text{I2CCLK}}\}$$

The  $t_{\text{SYNC1}}$  duration depends upon:

- SCL falling slope
- input delay  $t_{\text{AF(min)}} < t_{\text{AF}} < t_{\text{AF(max)}}$  introduced by the analog filter (if enabled)
- input delay  $t_{\text{DNF}} = \text{DNF} \times t_{\text{I2CCLK}}$  introduced by the digital filter (if enabled)
- delay due to SCL synchronization to I2CCLK clock (two to three I2CCLK periods)

To bridge the undefined region of the SCL falling edge, the user must set SDADEL[3:0] so as to fulfill the following condition:

$$\{t_{\text{f(max)}} + t_{\text{HD,DAT(min)}} - t_{\text{AF(min)}} - [(\text{DNF} + 3) \times t_{\text{I2CCLK}}]\} / \{(\text{PRESC} + 1) \times t_{\text{I2CCLK}}\} \leq \text{SDADEL}$$

$$\text{SDADEL} \leq \{t_{\text{HD,DAT(max)}} - t_{\text{AF(max)}} - [(\text{DNF} + 4) \times t_{\text{I2CCLK}}]\} / \{(\text{PRESC} + 1) \times t_{\text{I2CCLK}}\}$$

**Note:**  $t_{AF(min)}$  and  $t_{AF(max)}$  are only part of the condition when the analog filter is enabled. Refer to the device datasheet for  $t_{AF}$  values.

The  $t_{HD;DAT}$  time can at maximum be 3.45  $\mu$ s for Standard-mode, 0.9  $\mu$ s for Fast-mode, and 0.45  $\mu$ s for Fast-mode Plus. It must be lower than the maximum of  $t_{VD;DAT}$  by a transition time. This maximum must only be met if the device does not stretch the LOW period ( $t_{LOW}$ ) of the SCL signal. When it stretches SCL, the data must be valid by the set-up time before it releases the clock.

The SDA rising edge is usually the worst case. The previous condition then becomes:

$$SDADEL \leq \{t_{VD;DAT(max)} - t_r(max) - t_{AF(max)} - [(DNF + 4) \times t_{I2CCLK}]\} / \{(PRESC + 1) \times t_{I2CCLK}\}$$

**Note:** This condition can be violated when  $NOSTRETCH = 0$ , because the device stretches SCL low to guarantee the set-up time, according to the  $SCLDEL[3:0]$  value.

After  $t_{SDADEL}$ , or after sending SDA output when the slave had to stretch the clock because the data was not yet written in  $I2C\_TXDR$  register, the SCL line is kept at low level during the setup time. This setup time is  $t_{SCLDEL} = (SCLDEL + 1) \times t_{PRESC}$ , where  $t_{PRESC} = (PRESC + 1) \times t_{I2CCLK}$ .  $t_{SCLDEL}$  impacts the setup time  $t_{SU;DAT}$ .

To bridge the undefined region of the SDA transition (rising edge usually worst case), the user must program  $SCLDEL[3:0]$  so as to fulfill the following condition:

$$\{[t_r(max) + t_{SU;DAT(min)}] / [(PRESC + 1) \times t_{I2CCLK}] - 1 \leq SCLDEL$$

Refer to the following table for  $t_f$ ,  $t_r$ ,  $t_{HD;DAT}$ ,  $t_{VD;DAT}$ , and  $t_{SU;DAT}$  standard values.

Use the SDA and SCL real transition time values measured in the application to widen the scope of allowed  $SDADEL[3:0]$  and  $SCLDEL[3:0]$  values. Use the maximum SDA and SCL transition time values defined in the standard to make the device work reliably regardless of the application.

**Note:** At every clock pulse, after SCL falling edge detection, I2C operating as master or slave stretches SCL low during at least  $[(SDADEL + SCLDEL + 1) \times (PRESC + 1) + 1] \times t_{I2CCLK}$ , in both transmission and reception modes. In transmission mode, if the data is not yet written in  $I2C\_TXDR$  when SDA delay elapses, the I2C peripheral keeps stretching SCL low until the next data is written. Then new data MSB is sent on SDA output, and  $SCLDEL$  counter starts, continuing stretching SCL low to guarantee the data setup time.

When the  $NOSTRETCH$  bit is set in slave mode, the SCL is not stretched. The  $SDADEL[3:0]$  must then be programmed so that it ensures a sufficient setup time.

**Table 233. I<sup>2</sup>C-SMBus specification data setup and hold times**

| Symbol       | Parameter                             | Standard-mode (Sm) |      | Fast-mode (Fm) |     | Fast-mode Plus (Fm+) |      | SMBus |      | Unit    |
|--------------|---------------------------------------|--------------------|------|----------------|-----|----------------------|------|-------|------|---------|
|              |                                       | Min                | Max  | Min            | Max | Min                  | Max  | Min   | Max  |         |
| $t_{HD;DAT}$ | Data hold time                        | 0                  | -    | 0              | -   | 0                    | -    | 0.3   | -    | $\mu$ s |
| $t_{VD;DAT}$ | Data valid time                       | -                  | 3.45 | -              | 0.9 | -                    | 0.45 | -     | -    |         |
| $t_{SU;DAT}$ | Data setup time                       | 250                | -    | 100            | -   | 50                   | -    | 250   | -    | ns      |
| $t_r$        | Rise time of both SDA and SCL signals | -                  | 1000 | -              | 300 | -                    | 120  | -     | 1000 |         |
| $t_f$        | Fall time of both SDA and SCL signals | -                  | 300  | -              | 300 | -                    | 120  | -     | 300  |         |

Additionally, in master mode, the SCL clock high and low levels must be configured by programming the PRESC[3:0], SCLH[7:0], and SCLL[7:0] bitfields of the I2C\_TIMINGR register.

When the SCL falling edge is internally detected, the I2C peripheral releases the SCL output after the delay  $t_{SCLL} = (SCLL + 1) \times t_{PRESC}$ , where  $t_{PRESC} = (PRESC + 1) \times t_{I2CCCLK}$ . The  $t_{SCLL}$  delay impacts the SCL low time  $t_{LOW}$ .

When the SCL rising edge is internally detected, the I2C peripheral forces the SCL output to low level after the delay  $t_{SCLH} = (SCLH + 1) \times t_{PRESC}$ , where  $t_{PRESC} = (PRESC + 1) \times t_{I2CCCLK}$ . The  $t_{SCLH}$  impacts the SCL high time  $t_{HIGH}$ .

Refer to [I2C master initialization](#) for more details.

**Caution:** Changing the timing configuration and the NOSTRETCH configuration is not allowed when the I2C peripheral is enabled. Like the timing settings, the slave NOSTRETCH settings must also be done before enabling the peripheral. Refer to [I2C slave initialization](#) for more details.

**Figure 393. I2C initialization flow**

### 39.4.6 I2C reset

The reset of the I2C peripheral is performed by clearing the PE bit of the I2C\_CR1 register. It has the effect of releasing the SCL and SDA lines. Internal state machines are reset and the communication control bits and the status bits revert to their reset values. This reset does not impact the configuration registers.

The impacted register bits are:

1. I2C\_CR2 register: START, STOP, PECBYTE, and NACK
2. I2C\_ISR register: BUSY, TXE, TXIS, RXNE, ADDR, NACKF, TCR, TC, STOPF, BERR, ARLO, PECERR, TIMEOUT, ALERT, and OVR

PE must be kept low during at least three APB clock cycles to perform the I2C reset. To ensure this, perform the following software sequence:

1. Write PE = 0
2. Check PE = 0
3. Write PE = 1

### 39.4.7 Data transfer

The data transfer is managed through transmit and receive data registers and a shift register.

#### Reception

The SDA input fills the shift register. After the eighth SCL pulse (when the complete data byte is received), the shift register is copied into the I2C\_RXDR register if it is empty (RXNE = 0). If RXNE = 1, which means that the previous received data byte has not yet been read, the SCL line is stretched low until I2C\_RXDR is read. The stretch occurs between the eighth and ninth SCL pulse (before the acknowledge pulse).

**Figure 394. Data reception**

## Transmission

If the I2C\_TXDR register is not empty (TXE = 0), its content is copied into the shift register after the ninth SCL pulse (the acknowledge pulse). Then the shift register content is shifted out on the SDA line. If TXE = 1, which means that no data is written yet in I2C\_TXDR, the SCL line is stretched low until I2C\_TXDR is written. The stretch starts after the ninth SCL pulse.

**Figure 395. Data transmission**

## Hardware transfer management

The I2C features an embedded byte counter to manage byte transfer and to close the communication in various modes, such as:

- NACK, STOP and ReSTART generation in master mode
- ACK control in slave receiver mode
- PEC generation/checking

In master mode, the byte counter is always used. By default, it is disabled in slave mode. It can be enabled by software, by setting the SBC (slave byte control) bit of the I2C\_CR1 register.

The number of bytes to transfer is programmed in the NBYTES[7:0] bitfield of the I2C\_CR2 register. If this number is greater than 255, or if a receiver wants to control the acknowledge value of a received data byte, the reload mode must be selected, by setting the RELOAD bit of the I2C\_CR2 register. In this mode, the TCR flag is set when the number of bytes programmed in NBYTES[7:0] is transferred (when the associated counter reaches zero), and an interrupt is generated if TCIE is set. SCL is stretched as long as the TCR flag is set. TCR is cleared by software when NBYTES[7:0] is written to a non-zero value.

When NBYTES[7:0] is reloaded with the last number of bytes to transfer, the RELOAD bit must be cleared.

When RELOAD = 0 in master mode, the counter can be used in two modes:

- **Automatic end** (AUTOEND = 1 in the I2C\_CR2 register). In this mode, the master automatically sends a STOP condition once the number of bytes programmed in the NBYTES[7:0] bitfield is transferred.
- **Software end** (AUTOEND = 0 in the I2C\_CR2 register). In this mode, software action is expected once the number of bytes programmed in the NBYTES[7:0] bitfield is transferred; the TC flag is set and an interrupt is generated if the TCIE bit is set. The SCL signal is stretched as long as the TC flag is set. The TC flag is cleared by software when the START or STOP bit of the I2C\_CR2 register is set. This mode must be used when the master wants to send a RESTART condition.

**Caution:** The AUTOEND bit has no effect when the RELOAD bit is set.

**Table 234. I2C configuration**

| Function                              | SBC bit | RELOAD bit | AUTOEND bit |
|---------------------------------------|---------|------------|-------------|
| Master Tx/Rx NBYTES + STOP            | X       | 0          | 1           |
| Master Tx/Rx + NBYTES + RESTART       | X       | 0          | 0           |
| Slave Tx/Rx, all received bytes ACKed | 0       | X          | X           |
| Slave Rx with ACK control             | 1       | 1          | X           |

### 39.4.8 I2C slave mode

#### I2C slave initialization

To work in slave mode, the user must enable at least one slave address. The I2C\_OAR1 and I2C\_OAR2 registers are available to program the slave own addresses OA1 and OA2, respectively.

OA1 can be configured either in 7-bit (default) or in 10-bit addressing mode, by setting the OA1MODE bit of the I2C\_OAR1 register.

OA1 is enabled by setting the OA1EN bit of the I2C\_OAR1 register.

If an additional slave addresses are required, the second slave address OA2 can be configured. Up to seven OA2 LSBs can be masked, by configuring the OA2MSK[2:0] bitfield of the I2C\_OAR2 register. Therefore, for OA2MSK[2:0] configured from 1 to 6, only OA2[7:2], OA2[7:3], OA2[7:4], OA2[7:5], OA2[7:6], or OA2[7] are compared with the received address. When OA2MSK[2:0] is other than 0, the address comparator for OA2 excludes the I2C reserved addresses (0000 XXX and 1111 XXX) and they are not acknowledged. If OA2MSK[2:0] = 7, all received 7-bit addresses are acknowledged (except reserved addresses). OA2 is always a 7-bit address.

When enabled through the specific bit, the reserved addresses can be acknowledged if they are programmed in the I2C\_OAR1 or I2C\_OAR2 register with OA2MSK[2:0] = 0.

OA2 is enabled by setting the OA2EN bit of the I2C\_OAR2 register.

The general call address is enabled by setting the GCEN bit of the I2C\_CR1 register.

When the I2C peripheral is selected by one of its enabled addresses, the ADDR interrupt status flag is set, and an interrupt is generated if the ADDRIE bit is set.

By default, the slave uses its clock stretching capability, which means that it stretches the SCL signal at low level when required, to perform software actions. If the master does not

support clock stretching, I2C must be configured with NOSTRETCH = 1 in the I2C\_CR1 register.

After receiving an ADDR interrupt, if several addresses are enabled, the user must read the ADDCODE[6:0] bitfield of the I2C\_ISR register to check which address matched. The DIR flag must also be checked to know the transfer direction.

### Slave with clock stretching

As long as the NOSTRETCH bit of the I2C\_CR1 register is zero (default), the I2C peripheral operating as an I<sup>2</sup>C-bus slave stretches the SCL signal in the following situations:

- The ADDR flag is set and the received address matches with one of the enabled slave addresses.  
The stretch is released when the software clears the ADDR flag by setting the ADDRCONF bit.
- In transmission, the previous data transmission is completed and no new data is written in I2C\_TXDR register, or the first data byte is not written when the ADDR flag is cleared (TXE = 1).  
The stretch is released when the data is written to the I2C\_TXDR register.
- In reception, the I2C\_RXDR register is not read yet and a new data reception is completed.  
The stretch is released when I2C\_RXDR is read.
- In slave byte control mode (SBC bit set) with reload (RELOAD bit set), the last data byte transfer is finished (TCR bit set).  
The stretch is released when then TCR is cleared by writing a non-zero value in the NBYTES[7:0] bitfield.
- After SCL falling edge detection.  
The stretch is released after  $[(SDADEL + SCLDEL + 1) \times (PRESC + 1) + 1] \times t_{I2CCLK}$  period.

### Slave without clock stretching

As long as the NOSTRETCH bit of the I2C\_CR1 register is set, the I2C peripheral operating as an I<sup>2</sup>C-bus slave does not stretch the SCL signal.

The SCL clock is not stretched while the ADDR flag is set.

In transmission, the data must be written in the I2C\_TXDR register before the first SCL pulse corresponding to its transfer occurs. If not, an underrun occurs, the OVR flag is set in the I2C\_ISR register and an interrupt is generated if the ERRIE bit of the I2C\_CR1 register is set. The OVR flag is also set when the first data transmission starts and the STOPF bit is still set (has not been cleared). Therefore, if the user clears the STOPF flag of the previous transfer only after writing the first data to be transmitted in the next transfer, it ensures that the OVR status is provided, even for the first data to be transmitted.

In reception, the data must be read from the I2C\_RXDR register before the ninth SCL pulse (ACK pulse) of the next data byte occurs. If not, an overrun occurs, the OVR flag is set in the I2C\_ISR register, and an interrupt is generated if the ERRIE bit of the I2C\_CR1 register is set.

### Slave byte control mode

To allow byte ACK control in slave reception mode, the slave byte control mode must be enabled, by setting the SBC bit of the I2C\_CR1 register. This is required to comply with SMBus standards.

The reload mode must be selected to allow byte ACK control in slave reception mode (RELOAD = 1). To get control of each byte, NBYTES[7:0] must be initialized to 0x1 in the ADDR interrupt subroutine, and reloaded to 0x1 after each received byte. When the byte is received, the TCR bit is set, stretching the SCL signal low between the eighth and ninth SCL pulses. The user can read the data from the I2C\_RXDR register, and then decide to acknowledge it or not by configuring the ACK bit of the I2C\_CR2 register. The SCL stretch is released by programming NBYTES to a non-zero value: the acknowledge or not-acknowledge is sent, and the next byte can be received.

NBYTES[7:0] can be loaded with a value greater than 0x1. Receiving then continues until the corresponding number of bytes are received.

**Note:** The SBC bit must be configured when the I2C peripheral is disabled, when the slave is not addressed, or when ADDR = 1.

The RELOAD bit value can be changed when ADDR = 1, or when TCR = 1.

**Caution:** The slave byte control mode is not compatible with NOSTRETCH mode. Setting SBC when NOSTRETCH = 1 is not allowed.

**Figure 396. Slave initialization flow**

1. SBC must be set to support SMBus features.

### Slave transmitter

A transmit interrupt status (TXIS) flag is generated when the I2C\_TXDR register becomes empty. An interrupt is generated if the TXIE bit of the I2C\_CR1 register is set.

The TXIS flag is cleared when the I2C\_TXDR register is written with the next data byte to transmit.

When NACK is received, the NACKF flag is set in the I2C\_ISR register and an interrupt is generated if the NACKIE bit of the I2C\_CR1 register is set. The slave automatically releases the SCL and SDA lines to let the master perform a STOP or a RESTART condition. The TXIS bit is not set when a NACK is received.

When STOP is received and the STOPIE bit of the I2C\_CR1 register is set, the STOPF flag of the I2C\_ISR register is set and an interrupt is generated. In most applications, the SBC bit is usually programmed to 0. In this case, if TXE = 0 when the slave address is received (ADDR = 1), the user can choose either to send the content of the I2C\_TXDR register as the first data byte, or to flush the I2C\_TXDR register, by setting the TXE bit in order to program a new data byte.

In slave byte control mode (SBC = 1), the number of bytes to transmit must be programmed in NBYTES[7:0] in the address match interrupt subroutine (ADDR = 1). In this case, the number of TXIS events during the transfer corresponds to the value programmed in NBYTES[7:0].

**Caution:** When NOSTRETCH = 1, the SCL clock is not stretched while the ADDR flag is set, so the user cannot flush the I2C\_TXDR register content in the ADDR subroutine to program the first data byte. The first data byte to send must be previously programmed in the I2C\_TXDR register:

- This data can be the one written in the last TXIS event of the previous transmission message.
- If this data byte is not the one to send, the I2C\_TXDR register can be flushed, by setting the TXE bit, to program a new data byte. The STOPF bit must be cleared only after these actions. This guarantees that they are executed before the first data transmission starts, following the address acknowledge.

If STOPF is still set when the first data transmission starts, an underrun error is generated (the OVR flag is set).

If a TXIS event (transmit interrupt or transmit DMA request) is required, the user must set the TXIS bit in addition to the TXE bit, to generate the event.

Figure 397. Transfer sequence flow for I2C slave transmitter, NOSTRETCH = 0

Figure 398. Transfer sequence flow for I2C slave transmitter, NOSTRETCH = 1

**Figure 399. Transfer bus diagrams for I2C slave transmitter (mandatory events only)**

Example I2C slave transmitter 3 bytes with 1st data flushed,  
NOSTRETCH=0:

EV1: ADDR ISR: check ADDCODE and DIR, set TXE, set ADDRCF

EV2: TXIS ISR: wr data1

EV3: TXIS ISR: wr data2

EV4: TXIS ISR: wr data3

EV5: TXIS ISR: wr data4 (not sent)

Example I2C slave transmitter 3 bytes without 1st data flush,  
NOSTRETCH=0:

EV1: ADDR ISR: check ADDCODE and DIR, set ADDRCF

EV2: TXIS ISR: wr data2

EV3: TXIS ISR: wr data3

EV4: TXIS ISR: wr data4 (not sent)

Example I2C slave transmitter 3 bytes, NOSTRETCH=1:

EV1: wr data1

EV2: TXIS ISR: wr data2

EV3: TXIS ISR: wr data3

EV4: TXIS ISR: wr data4 (not sent)

EV5: STOPF ISR: (optional: set TXE and TXIS), set STOPCF

MS19853V2

### Slave receiver

The RXNE bit of the I2C\_ISR register is set when the I2C\_RXDR is full, which generates an interrupt if the RXIE bit of the I2C\_CR1 register is set. RXNE is cleared when I2C\_RXDR is read.

When a STOP is received and STOPIE is set in I2C\_CR1, STOPF is set in I2C\_ISR and an interrupt is generated.

**Figure 400. Transfer sequence flow for I2C slave receiver, NOSTRETCH = 0**

### 39.4.9 I2C master mode

#### I2C master initialization

Before enabling the peripheral, the I2C master clock must be configured, by setting the SCLH and SCLL bits in the I2C\_TIMINGR register.

The STM32CubeMX tool calculates and provides the I2C\_TIMINGR content in the *I2C Configuration* window.

A clock synchronization mechanism is implemented in order to support multi-master environment and slave clock stretching.

In order to allow clock synchronization:

- The low level of the clock is counted using the SCLL counter, starting from the SCL low level internal detection.
- The high level of the clock is counted using the SCLH counter, starting from the SCL high level internal detection.

I2C detects its own SCL low level after a  $t_{\text{SYNC1}}$  delay depending on the SCL falling edge, SCL input noise filters (analog and digital), and SCL synchronization to the I2CxCLK clock. I2C releases SCL to high level once the SCLL counter reaches the value programmed in the SCLL[7:0] bitfield of the I2C\_TIMINGR register.

I2C detects its own SCL high level after a  $t_{\text{SYNC2}}$  delay depending on the SCL rising edge, SCL input noise filters (analog and digital), and SCL synchronization to the I2CxCLK clock. I2C ties SCL to low level once the SCLH counter reaches the value programmed in the SCLH[7:0] bitfield of the I2C\_TIMINGR register.

Consequently the master clock period is:

$$t_{\text{SCL}} = t_{\text{SYNC1}} + t_{\text{SYNC2}} + \{[(\text{SCLH} + 1) + (\text{SCLL} + 1)] \times (\text{PRESC} + 1) \times t_{\text{I2CCLK}}\}$$

The duration of  $t_{\text{SYNC1}}$  depends upon:

- SCL falling slope
- input delay induced by the analog filter (when enabled)
- input delay induced by the digital filter (when enabled):  $\text{DNF}[3:0] \times t_{\text{I2CCLK}}$
- delay due to SCL synchronization with the I2CCLK clock (two to three I2CCLK periods)

The duration of  $t_{\text{SYNC2}}$  depends upon:

- SCL rising slope
- input delay induced by the analog filter (when enabled)
- input delay induced by the digital filter (when enabled):  $\text{DNF}[3:0] \times t_{\text{I2CCLK}}$
- delay due to SCL synchronization with the I2CCLK clock (two to three I2CCLK periods)

Figure 403. Master clock generation

**Caution:** For compliance with the I<sup>2</sup>C-bus or SMBus specification, the master clock must respect the timings in the following table.

**Table 235. I<sup>2</sup>C-SMBus specification clock timings**

| Symbol              | Parameter                                        | Standard-mode (Sm) |      | Fast-mode (Fm) |     | Fast-mode Plus (Fm+) |      | SMBus |      | Unit |
|---------------------|--------------------------------------------------|--------------------|------|----------------|-----|----------------------|------|-------|------|------|
|                     |                                                  | Min                | Max  | Min            | Max | Min                  | Max  | Min   | Max  |      |
| f <sub>SCL</sub>    | SCL clock frequency                              | -                  | 100  | -              | 400 | -                    | 1000 | -     | 100  | kHz  |
| t <sub>HD:STA</sub> | Hold time (repeated) START condition             | 4.0                | -    | 0.6            | -   | 0.26                 | -    | 4.0   | -    | μs   |
| t <sub>SU:STA</sub> | Set-up time for a repeated START condition       | 4.7                | -    | 0.6            | -   | 0.26                 | -    | 4.7   | -    |      |
| t <sub>SU:STO</sub> | Set-up time for STOP condition                   | 4.0                | -    | 0.6            | -   | 0.26                 | -    | 4.0   | -    |      |
| t <sub>BUF</sub>    | Bus free time between a STOP and START condition | 4.7                | -    | 1.3            | -   | 0.5                  | -    | 4.7   | -    |      |
| t <sub>LOW</sub>    | Low period of the SCL clock                      | 4.7                | -    | 1.3            | -   | 0.5                  | -    | 4.7   | -    |      |
| t <sub>HIGH</sub>   | High period of the SCL clock                     | 4.0                | -    | 0.6            | -   | 0.26                 | -    | 4.0   | 50   |      |
| t <sub>r</sub>      | Rise time of both SDA and SCL signals            | -                  | 1000 | -              | 300 | -                    | 120  | -     | 1000 | ns   |
| t <sub>f</sub>      | Fall time of both SDA and SCL signals            | -                  | 300  | -              | 300 | -                    | 120  | -     | 300  |      |

**Note:** The SCLL[7:0] bitfield also determines the t<sub>BUF</sub> and t<sub>SU:STA</sub> timings and SCLH[7:0] the t<sub>HD:STA</sub> and t<sub>SU:STO</sub> timings.

Refer to [Section 39.4.10](#) for examples of I2C\_TIMINGR settings versus the I2CCLK frequency.

### Master communication initialization (address phase)

To initiate the communication with a slave to address, set the following bitfields of the I2C\_CR2 register:

- ADD10: addressing mode (7-bit or 10-bit)
- SADD[9:0]: slave address to send
- RD\_WRN: transfer direction
- HEAD10R: in case of 10-bit address read, this bit determines whether the header only (for direction change) or the complete address sequence is sent.
- NBYTES[7:0]: the number of bytes to transfer; if equal to or greater than 255 bytes, the bitfield must initially be set to 0xFF.

**Note:** Changing these bitfields is not allowed as long as the START bit is set.

Before launching the communication, make sure that the I<sup>2</sup>C-bus is idle. This can be checked using the bus idle detection function or by verifying that the IDR bits of the GPIOs selected as SDA and SCL are set. Any low-level incident on the I<sup>2</sup>C-bus lines that coincides with the START condition asserted by the I2C peripheral may cause its deadlock if not filtered out by the input filters. If such incidents cannot be prevented, design the software so that it restores the normal operation of the I2C peripheral in case of a deadlock, by toggling the PE bit of the I2C\_CR1 register.

To launch the communication, set the START bit of the I2C\_CR2 register. The master then automatically sends a START condition followed by the slave address as soon as it detects that the bus is free (BUSY = 0) and after the  $t_{BUF}$  delay from a previous STOP condition expires.

In case of an arbitration loss, the master automatically switches back to slave mode and can acknowledge its own address if it is addressed as a slave.

**Note:** *The START bit is reset by hardware when the slave address is sent on the bus, whatever the received acknowledge value. The START bit is also reset by hardware upon arbitration loss.*

*In 10-bit addressing mode, the master automatically keeps resending the slave address in a loop until the first address byte (first seven address bits) is acknowledged by the slave.*

*Setting the ADDRCONF bit makes I2C quit that loop.*

*If the I2C peripheral is addressed as a slave (ADDR = 1) while the START bit is set, the I2C peripheral switches to slave mode and the START bit is cleared when the ADDRCONF bit is set.*

**Note:** *The same procedure is applied for a repeated start condition. In this case, BUSY = 1.*

**Figure 404. Master initialization flow**

### Initialization of a master receiver addressing a 10-bit address slave

If the slave address is in 10-bit format, the user can choose to send the complete read sequence, by clearing the HEAD10R bit of the I2C\_CR2 register. In this case, the master automatically sends the following complete sequence after the START bit is set:

(RE)START + Slave address 10-bit header Write + Slave address second byte +  
(RE)START + Slave address 10-bit header Read.

**Figure 405. 10-bit address read access with HEAD10R = 0**

If the master addresses a 10-bit address slave, transmits data to this slave and then reads data from the same slave, a master transmission flow must be done first. Then a repeated START is set with the 10-bit slave address configured with HEAD10R = 1. In this case, the master sends this sequence:

RESTART + Slave address 10-bit header Read.

**Figure 406. 10-bit address read access with HEAD10R = 1**

### Master transmitter

In the case of a write transfer, the TXIS flag is set after each byte transmission, after the ninth SCL pulse when an ACK is received.

A TXIS event generates an interrupt if the TXIE bit of the I2C\_CR1 register is set. The flag is cleared when the I2C\_TXDR register is written with the next data byte to transmit.

The number of TXIS events during the transfer corresponds to the value programmed in NBYTES[7:0]. If the total number of data bytes to transmit is greater than 255, the reload mode must be selected by setting the RELOAD bit in the I2C\_CR2 register. In this case, when the NBYTES[7:0] number of data bytes is transferred, the TCR flag is set and the SCL line is stretched low until NBYTES[7:0] is written with a non-zero value.

When RELOAD = 0 and the number of data bytes defined in NBYTES[7:0] is transferred:

- In automatic end mode (AUTOEND = 1), a STOP condition is automatically sent.
- In software end mode (AUTOEND = 0), the TC flag is set and the SCL line is stretched low, to perform software actions:
  - A RESTART condition can be requested by setting the START bit of the I2C\_CR2 register with the proper slave address configuration and the number of bytes to transfer. Setting the START bit clears the TC flag and sends the START condition on the bus.
  - A STOP condition can be requested by setting the STOP bit of the I2C\_CR2 register. This clears the TC flag and sends a STOP condition on the bus.

When a NACK is received, the TXIS flag is not set and a STOP condition is automatically sent. the NACKF flag of the I2C\_ISR register is set. An interrupt is generated if the NACKIE bit is set.

Figure 407. Transfer sequence flow for I2C master transmitter,  $N \leq 255$  bytes

Figure 408. Transfer sequence flow for I2C master transmitter, N &gt; 255 bytes

**Figure 409. Transfer bus diagrams for I2C master transmitter (mandatory events only)**

**Example I2C master transmitter 2 bytes, automatic end mode (STOP)**

**Example I2C master transmitter 2 bytes, software end mode (RESTART)**

MS19862V2

### Master receiver

In the case of a read transfer, the RXNE flag is set after each byte reception, after the eighth SCL pulse. An RXNE event generates an interrupt if the RXIE bit of the I2C\_CR1 register is set. The flag is cleared when I2C\_RXDR is read.

If the total number of data bytes to receive is greater than 255, select the reload mode, by setting the RELOAD bit of the I2C\_CR2 register. In this case, when the NBYTES[7:0] number of data bytes is transferred, the TCR flag is set and the SCL line is stretched low until NBYTES[7:0] is written with a non-zero value.

When RELOAD = 0 and the number of data bytes defined in NBYTES[7:0] is transferred:

- In automatic end mode (AUTOEND = 1), a NACK and a STOP are automatically sent after the last received byte.
- In software end mode (AUTOEND = 0), a NACK is automatically sent after the last received byte. The TC flag is set and the SCL line is stretched low in order to allow software actions:
  - A RESTART condition can be requested by setting the START bit of the I2C\_CR2 register, with the proper slave address configuration and the number of bytes to transfer. Setting the START bit clears the TC flag and the START condition, followed by slave address, are sent on the bus.
  - A STOP condition can be requested by setting the STOP bit of the I2C\_CR2 register. This clears the TC flag and sends a STOP condition on the bus.

### 39.4.10 I2C\_TIMINGR register configuration examples

The following tables provide examples of how to program the I2C\_TIMINGR to obtain timings compliant with the I<sup>2</sup>C-bus specification. To get more accurate configuration values, use the STM32CubeMX tool (*I2C Configuration* window).

Table 236. Timing settings for  $f_{I2CCLK}$  of 8 MHz

| Parameter       | Standard-mode (Sm)          |                            | Fast-mode (Fm)              | Fast-mode Plus (Fm+)        |
|-----------------|-----------------------------|----------------------------|-----------------------------|-----------------------------|
|                 | 10 kHz                      | 100 kHz                    | 400 kHz                     | 500 kHz                     |
| PRESC[3:0]      | 0x1                         | 0x1                        | 0x0                         | 0x0                         |
| SCLL[7:0]       | 0xC7                        | 0x13                       | 0x9                         | 0x6                         |
| $t_{SCLL}$      | 200 x 250 ns = 50 $\mu$ s   | 20 x 250 ns = 5.0 $\mu$ s  | 10 x 125 ns = 1250 ns       | 7 x 125 ns = 875 ns         |
| SCLH[7:0]       | 0xC3                        | 0xF                        | 0x3                         | 0x3                         |
| $t_{SCLH}$      | 196 x 250 ns = 49 $\mu$ s   | 16 x 250 ns = 4.0 $\mu$ s  | 4 x 125 ns = 500 ns         | 4 x 125 ns = 500 ns         |
| $t_{SCL}^{(1)}$ | ~100 $\mu$ s <sup>(2)</sup> | ~10 $\mu$ s <sup>(2)</sup> | ~2.5 $\mu$ s <sup>(3)</sup> | ~2.0 $\mu$ s <sup>(4)</sup> |
| SDADEL[3:0]     | 0x2                         | 0x2                        | 0x1                         | 0x0                         |
| $t_{SDADEL}$    | 2 x 250 ns = 500 ns         | 2 x 250 ns = 500 ns        | 1 x 125 ns = 125 ns         | 0 ns                        |
| SCLDEL[3:0]     | 0x4                         | 0x4                        | 0x3                         | 0x1                         |
| $t_{SCLDEL}$    | 5 x 250 ns = 1250 ns        | 5 x 250 ns = 1250 ns       | 4 x 125 ns = 500 ns         | 2 x 125 ns = 250 ns         |

- $t_{SCL}$  is greater than  $t_{SCLL} + t_{SCLH}$  due to SCL internal detection delay. Values provided for  $t_{SCL}$  are examples only.
- $t_{SYNC1} + t_{SYNC2}$  minimum value is  $4 \times t_{I2CCLK} = 500$  ns. Example with  $t_{SYNC1} + t_{SYNC2} = 1000$  ns.
- $t_{SYNC1} + t_{SYNC2}$  minimum value is  $4 \times t_{I2CCLK} = 500$  ns. Example with  $t_{SYNC1} + t_{SYNC2} = 750$  ns.
- $t_{SYNC1} + t_{SYNC2}$  minimum value is  $4 \times t_{I2CCLK} = 500$  ns. Example with  $t_{SYNC1} + t_{SYNC2} = 655$  ns.

Table 237. Timing settings for  $f_{I2CCLK}$  of 16 MHz

| Parameter       | Standard-mode (Sm)          |                            | Fast-mode (Fm)              | Fast-mode Plus (Fm+)        |

### 39.4.11 SMBus specific features

#### Introduction

The system management bus (SMBus) is a two-wire interface through which various devices can communicate with each other and with the rest of the system. It is based on operation principles of the I<sup>2</sup>C-bus. The SMBus provides a control bus for system and power management related tasks.

The I2C peripheral is compatible with the SMBus specification (<http://smbus.org>).

The system management bus specification refers to three types of devices:

- **Slave** is a device that receives or responds to a command.
- **Master** is a device that issues commands, generates clocks, and terminates the transfer.
- **Host** is a specialized master that provides the main interface to the system CPU. A host must be a master-slave and must support the SMBus *host notify* protocol. Only one host is allowed in a system.

The I2C peripheral can be configured as a master or a slave device, and also as a host.

#### Bus protocols

There are eleven possible command protocols for any given device. A device can use any or all of them to communicate. The protocols are: *Quick Command*, *Send Byte*, *Receive Byte*, *Write Byte*, *Write Word*, *Read Byte*, *Read Word*, *Process Call*, *Block Read*, *Block Write*, and *Block Write-Block Read Process Call*. The protocols must be implemented by the user software.

For more details on these protocols, refer to the SMBus specification (<http://smbus.org>). STM32CubeMX implements an SMBus stack thanks to X-CUBE-SMBUS, a downloadable software pack that allows basic SMBus configuration per I2C instance.

### Address resolution protocol (ARP)

SMBus slave address conflicts can be resolved by dynamically assigning a new unique address to each slave device. To provide a mechanism to isolate each device for the purpose of address assignment, each device must implement a unique 128-bit device identifier (UDID). In the I2C peripheral, is implemented by software.

The I2C peripheral supports the Address resolution protocol (ARP). The SMBus device default address (0b1100 001) is enabled by setting the SMBDEN bit of the I2C\_CR1 register. The ARP commands must be implemented by the user software.

Arbitration is also performed in slave mode for ARP support.

For more details on the SMBus address resolution protocol, refer to the SMBus specification (<http://smbus.org>).

### Received command and data acknowledge control

A SMBus receiver must be able to NACK each received command or data. In order to allow the ACK control in slave mode, the slave byte control mode must be enabled, by setting the SBC bit of the I2C\_CR1 register. Refer to [Slave byte control mode](#) for more details.

### Host notify protocol

To enable the host notify protocol, set the SMBHEN bit of the I2C\_CR1 register. The I2C peripheral then acknowledges the SMBus host address (0b0001 000).

When this protocol is used, the device acts as a master and the host as a slave.

### SMBus alert

The I2C peripheral supports the SMBALERT# optional signal through the SMBA pin. With the SMBALERT# signal, an SMBus slave device can signal to the SMBus host that it wants to talk. The host processes the interrupt and simultaneously accesses all SMBALERT# devices through the alert response address (0b0001 100). Only the device/devices which pulled SMBALERT# low acknowledges/acknowledge the alert response address.

When the I2C peripheral is configured as an SMBus slave device (SMBHEN = 0), the SMBA pin is pulled low by setting the ALERTEN bit of the I2C\_CR1 register. The alert response address is enabled at the same time.

When the I2C peripheral is configured as an SMBus host (SMBHEN = 1), the ALERT flag of the I2C\_ISR register is set when a falling edge is detected on the SMBA pin and ALERTEN = 1. An interrupt is generated if the ERRIE bit of the I2C\_CR1 register is set. When ALERTEN = 0, the alert line is considered high even if the external SMBA pin is low.

*Note:* If the SMBus alert pin is not required, keep the ALERTEN bit cleared. The SMBA pin can then be used as a standard GPIO.

### Packet error checking

A packet error checking mechanism introduced in the SMBus specification improves reliability and communication robustness. The packet error checking is implemented by appending a packet error code (PEC) at the end of each message transfer. The PEC is

calculated by using the  $C(x) = x^8 + x^2 + x + 1$  CRC-8 polynomial on all the message bytes (including addresses and read/write bits).

The I2C peripheral embeds a hardware PEC calculator and allows a not acknowledge to be sent automatically when the received byte does not match the hardware calculated PEC.

## Timeouts

To comply with the SMBus timeout specifications, the I2C peripheral embeds hardware timers.

**Table 239. SMBus timeout specifications**

| Symbol                      | Parameter                                        | Limits |     | Unit |
|-----------------------------|--------------------------------------------------|--------|-----|------|
|                             |                                                  | Min    | Max |      |
| $t_{\text{TIMEOUT}}$        | Detect clock low timeout                         | 25     | 35  | ms   |
| $t_{\text{LOW:SEXT}}^{(1)}$ | Cumulative clock low extend time (slave device)  | -      | 25  |      |
| $t_{\text{LOW:MEXT}}^{(2)}$ | Cumulative clock low extend time (master device) | -      | 10  |      |

1.  $t_{\text{LOW:SEXT}}$  is the cumulative time a given slave device is allowed to extend the clock cycles in one message from the initial START to the STOP. It is possible that another slave device or the master also extends the clock causing the combined clock low extend time to be greater than  $t_{\text{LOW:SEXT}}$ . Therefore, this parameter is measured with the slave device as the sole target of a full-speed master.
2.  $t_{\text{LOW:MEXT}}$  is the cumulative time a master device is allowed to extend its clock cycles within each byte of a message as defined from START-to-ACK, ACK-to-ACK, or ACK-to-STOP. It is possible that a slave device or another master also extends the clock, causing the combined clock low time to be greater than  $t_{\text{LOW:MEXT}}$  on a given byte. Therefore, this parameter is measured with a full speed slave device as the sole target of the master.

**Figure 413. Timeout intervals for  $t_{\text{LOW:SEXT}}$ ,  $t_{\text{LOW:MEXT}}$**

### Bus idle detection

A master can assume that the bus is free if it detects that the clock and data signals have been high for  $t_{IDLE} > t_{HIGH,MAX}$  (refer to [I2C timings](#)).

This timing parameter covers the condition where a master is dynamically added to the bus, and may not have detected a state transition on the SMBCLK or SMBDAT lines. In this case, the master must wait long enough to ensure that a transfer is not currently in progress. The I2C peripheral supports a hardware bus idle detection.

## 39.4.12 SMBus initialization

In addition to the I2C initialization for the I<sup>2</sup>C-bus, the use of the peripheral for the SMBus communication requires some extra initialization steps.

### Received command and data acknowledge control (slave mode)

An SMBus receiver must be able to NACK each received command or data. To allow ACK control in slave mode, the slave byte control mode must be enabled, by setting the SBC bit of the I2C\_CR1 register. Refer to [Slave byte control mode](#) for more details.

### Specific addresses (slave mode)

The specific SMBus addresses must be enabled if required. Refer to [Bus idle detection](#) for more details.

The SMBus device default address (0b1100 001) is enabled by setting the SMBDEN bit of the I2C\_CR1 register.

The SMBus host address (0b0001 000) is enabled by setting the SMBHEN bit of the I2C\_CR1 register.

The alert response address (0b0001100) is enabled by setting the ALERTEN bit of the I2C\_CR1 register.

### Packet error checking

PEC calculation is enabled by setting the PECEN bit of the I2C\_CR1 register. Then the PEC transfer is managed with the help of the hardware byte counter associated with the NBYTES[7:0] bitfield of the I2C\_CR2 register. The PECEN bit must be configured before enabling the I2C.

The PEC transfer is managed with the hardware byte counter, so the SBC bit must be set when interfacing the SMBus in slave mode. The PEC is transferred after transferring NBYTES[7:0] - 1 data bytes, if the PECBYTE bit is set and the RELOAD bit is cleared. If RELOAD is set, PECBYTE has no effect.

**Caution:** Changing the PECEN configuration is not allowed when the I2C peripheral is enabled.

**Table 240. SMBus with PEC configuration**

| Mode                                | SBC bit | RELOAD bit | AUTOEND bit | PECBYTE bit |
|-------------------------------------|---------|------------|-------------|-------------|
| Master Tx/Rx NBYTES + PEC+ STOP     | X       | 0          | 1           | 1           |
| Master Tx/Rx NBYTES + PEC + ReSTART | X       | 0          | 0           | 1           |
| Slave Tx/Rx with PEC                | 1       | 0          | X           | 1           |

### Timeout detection

The timeout detection is enabled by setting the TIMOUTEN and TEXTEN bits of the I2C\_TIMEOUTR register. The timers must be programmed in such a way that they detect a timeout before the maximum time given in the SMBus specification.

#### *t<sub>TIMEOUT</sub> check*

To check the  $t_{\text{TIMEOUT}}$  parameter, load the 12-bit TIMEOUTA[11:0] bitfield with the timer reload value. Keep the TIDLE bit at 0 to detect the SCL low level timeout.

Then set the TIMOUTEN bit of the I2C\_TIMEOUTR register, to enable the timer.

If SCL is tied low for longer than the  $(\text{TIMEOUTA} + 1) \times 2048 \times t_{\text{I2CCLK}}$  period, the TIMEOUT flag of the I2C\_ISR register is set.

Refer to [Table 241](#).

**Caution:** Changing the TIMEOUTA[11:0] bitfield and the TIDLE bit values is not allowed when the TIMOUTEN bit is set.

#### *t<sub>LOW:SEXT</sub> and t<sub>LOW:MEXT</sub> check*

A 12-bit timer associated with the TIMEOUTB[11:0] bitfield allows checking  $t_{\text{LOW:SEXT}}$  for the I2C peripheral operating as a slave, or  $t_{\text{LOW:MEXT}}$  when it operates as a master. As the standard only specifies a maximum, the user can choose the same value for both. The timer is then enabled by setting the TEXTEN bit in the I2C\_TIMEOUTR register.

If the SMBus peripheral performs a cumulative SCL stretch for longer than the  $(\text{TIMEOUTB} + 1) \times 2048 \times t_{\text{I2CCLK}}$  period, and within the timeout interval described in [Bus idle detection](#) section, the TIMEOUT flag of the I2C\_ISR register is set.

Refer to [Table 242](#).

**Caution:** Changing the TIMEOUTB[11:0] bitfield value is not allowed when the TEXTEN bit is set.

### Bus idle detection

To check the  $t_{\text{IDLE}}$  period, the TIMEOUTA[11:0] bitfield associated with 12-bit timer must be loaded with the timer reload value. Keep the TIDLE bit at 1 to detect both SCL and SDA high level timeout. Then set the TIMOUTEN bit of the I2C\_TIMEOUTR register to enable the timer.

If both the SCL and SDA lines remain high for longer than the  $(\text{TIMEOUTA} + 1) \times 4 \times t_{\text{I2CCLK}}$  period, the TIMEOUT flag of the I2C\_ISR register is set.

Refer to [Table 243](#).

**Caution:** Changing the TIMEOUTA[11:0] bitfield and the TIDLE bit values is not allowed when the TIMOUTEN bit is set.

### 39.4.13 SMBus I2C\_TIMEOUTR register configuration examples

The following tables provide examples of settings to reach target  $t_{\text{TIMEOUT}}$ ,  $t_{\text{LOW:SEXT}}$ ,  $t_{\text{LOW:MEXT}}$ , and  $t_{\text{IDLE}}$  timings at different  $f_{\text{I2CCLK}}$  frequencies.

**Table 241. TIMEOUTA[11:0] for maximum  $t_{\text{TIMEOUT}}$  of 25 ms**

| $f_{\text{I2CCLK}}$ | TIMEOUTA[11:0] | TIDLE | TIMEOUTEN | $t_{\text{TIMEOUT}}$                                      |
|---------------------|----------------|-------|-----------|-----------------------------------------------------------|

| 48 MHz              | 0x257          | 1     | 1         | $600 \times 4 \times 20.08 \text{ ns} = 50 \mu\text{s}$ |

### 39.4.14 SMBus slave mode

In addition to I2C slave transfer management (refer to [Section 39.4.8: I2C slave mode](#)), this section provides extra software flowcharts to support SMBus.

#### SMBus slave transmitter

When using the I2C peripheral in SMBus mode, set the SBC bit to enable the PEC transmission at the end of the programmed number of data bytes. When the PECBYTE bit is set, the number of bytes programmed in NBYTES[7:0] includes the PEC transmission. In that case, the total number of TXIS interrupts is NBYTES[7:0] - 1, and the content of the I2C\_PECR register is automatically transmitted if the master requests an extra byte after the transfer of the NBYTES[7:0] - 1 data bytes.

**Caution:** The PECBYTE bit has no effect when the RELOAD bit is set.

Figure 414. Transfer sequence flow for SMBus slave transmitter N bytes + PEC

Figure 415. Transfer bus diagram for SMBus slave transmitter (SBC = 1)

### SMBus slave receiver

When using the I2C peripheral in SMBus mode, set the SBC bit to enable the PEC checking at the end of the programmed number of data bytes. To allow the ACK control of each byte, the reload mode must be selected (RELOAD = 1). Refer to [Slave byte control mode](#) for more details.

To check the PEC byte, the RELOAD bit must be cleared and the PECBYTE bit must be set. In this case, after the receipt of NBYTES[7:0] - 1 data bytes, the next received byte is compared with the internal I2C\_PECR register content. A NACK is automatically generated if the comparison does not match, and an ACK is automatically generated if the comparison matches, whatever the ACK bit value. Once the PEC byte is received, it is copied into the I2C\_RXDR register like any other data, and the RXNE flag is set.

Upon a PEC mismatch, the PECERR flag is set and an interrupt is generated if the ERRIE bit of the I2C\_CR1 register is set.

If no ACK software control is required, the user can set the PECBYTE bit and, in the same write operation, load NBYTES[7:0] with the number of bytes to receive in a continuous flow. After the receipt of NBYTES[7:0] - 1 bytes, the next received byte is checked as being the PEC.

**Caution:** The PECBYTE bit has no effect when the RELOAD bit is set.

Figure 416. Transfer sequence flow for SMBus slave receiver N bytes + PEC

**Figure 417. Bus transfer diagrams for SMBus slave receiver (SBC = 1)**

### 39.4.15 SMBus master mode

In addition to I2C master transfer management (refer to [Section 39.4.9: I2C master mode](#)), this section provides extra software flowcharts to support SMBus.

#### SMBus master transmitter

When the SMBus master wants to transmit the PEC, the PECBYTE bit must be set and the number of bytes must be loaded in the NBYTES[7:0] bitfield, before setting the START bit. In this case, the total number of TXIS interrupts is NBYTES[7:0] - 1. So if the PECBYTE bit is set when NBYTES[7:0] = 0x1, the content of the I2C\_PECR register is automatically transmitted.

If the SMBus master wants to send a STOP condition after the PEC, the automatic end mode must be selected (AUTOEND = 1). In this case, the STOP condition automatically follows the PEC transmission.

When the SMBus master wants to send a RESTART condition after the PEC, the software mode must be selected (AUTOEND = 0). In this case, once NBYTES[7:0] - 1 are transmitted, the I2C\_PECR register content is transmitted. The TC flag is set after the PEC transmission, stretching the SCL line low. The RESTART condition must be programmed in the TC interrupt subroutine.

**Caution:** The PECBYTE bit has no effect when the RELOAD bit is set.

**Figure 418. Bus transfer diagrams for SMBus master transmitter**

### SMBus master receiver

When the SMBus master wants to receive, at the end of the transfer, the PEC followed by a STOP condition, the automatic end mode can be selected (AUTOEND = 1). The PECBYTE bit must be set and the slave address programmed before setting the START bit. In this case, after the receipt of NBYTES[7:0] - 1 data bytes, the next received byte is automatically checked versus the I2C\_PECR register content. A NACK response is given to the PEC byte, followed by a STOP condition.

When the SMBus master receiver wants to receive, at the end of the transfer, the PEC byte followed by a RESTART condition, the software mode must be selected (AUTOEND = 0). The PECBYTE bit must be set and the slave address programmed before setting the START bit. In this case, after NBYTES - 1 data have been received, the next received byte is automatically checked versus the I2C\_PECR register content. The TC flag is set after the PEC byte reception, stretching the SCL line low. The RESTART condition can be programmed in the TC interrupt subroutine.

**Caution:** The PECBYTE bit has no effect when the RELOAD bit is set.

**Figure 419. Bus transfer diagrams for SMBus master receiver**

Example SMBus master receiver 2 bytes + PEC, automatic end mode (STOP)

Example SMBus master receiver 2 bytes + PEC, software end mode (RESTART)

MS19872V2

### 39.4.16 Wake-up from Stop mode on address match

The I2C peripheral is able to wake up the device from Stop mode (APB clock is off), when the device is addressed. All addressing modes are supported.

The wake-up from Stop mode is enabled by setting the WUPEN bit of the I2C\_CR1 register. The HSI16 oscillator must be selected as the clock source for I2CCLK to allow the wake-up from Stop mode.

In Stop mode, the HSI16 oscillator is stopped. Upon detecting START condition, the I2C interface starts the HSI16 oscillator and stretches SCL low until the oscillator wakes up.

HSI16 is then used for the address reception.

If the received address matches the device own address, I2C stretches SCL low until the device wakes up. The stretch is released when the ADDR flag is cleared by software. Then the transfer goes on normally.

If the address does not match, the HSI16 oscillator is stopped again and the device does not wake up.

**Note:** *When the system clock is used as I2C clock, or when WUPEN = 0, the HSI16 oscillator does not start upon receiving START condition.*

*Only an ADDR interrupt can wake the device up. Therefore, do not enter Stop mode when I2C is performing a transfer, either as a master or as an addressed slave after the ADDR flag is set. This can be managed by clearing the SLEEPDEEP bit in the ADDR interrupt routine and setting it again only after the STOPF flag is set.*

**Caution:** The digital filter is not compatible with the wake-up from Stop mode feature. Before entering Stop mode with the WUPEN bit set, deactivate the digital filter, by writing zero to the DNF[3:0] bitfield.

**Caution:** The feature is only available when the HSI16 oscillator is selected as the I2C clock.

**Caution:** Clock stretching must be enabled (NOSTRETCH = 0) to ensure proper operation of the wake-up from Stop mode feature.

**Caution:** If the wake-up from Stop mode is disabled (WUPEN = 0), the I2C peripheral must be disabled before entering Stop mode (PE = 0).

### 39.4.17 Error conditions

The following errors are the conditions that can cause the communication to fail.

#### Bus error (BERR)

A bus error is detected when a START or a STOP condition is detected and is not located after a multiple of nine SCL clock pulses. START or STOP condition is detected when an SDA edge occurs while SCL is high.

The bus error flag is set only if the I2C peripheral is involved in the transfer as master or addressed slave (that is, not during the address phase in slave mode).

In case of a misplaced START or RESTART detection in slave mode, the I2C peripheral enters address recognition state like for a correct START condition.

When a bus error is detected, the BERR flag of the I2C\_ISR register is set, and an interrupt is generated if the ERRIE bit of the I2C\_CR1 register is set.

#### Arbitration loss (ARLO)

An arbitration loss is detected when a high level is sent on the SDA line, but a low level is sampled on the SCL rising edge.

In master mode, arbitration loss is detected during the address phase, data phase and data acknowledge phase. In this case, the SDA and SCL lines are released, the START control bit is cleared by hardware and the master switches automatically to slave mode.

In slave mode, arbitration loss is detected during data phase and data acknowledge phase. In this case, the transfer is stopped and the SCL and SDA lines are released.

When an arbitration loss is detected, the ARLO flag of the I2C\_ISR register is set and an interrupt is generated if the ERRIE bit of the I2C\_CR1 register is set.

### Overrun/underrun error (OVR)

An overrun or underrun error is detected in slave mode when NOSTRETCH = 1 and:

- In reception when a new byte is received and the RXDR register has not been read yet. The new received byte is lost, and a NACK is automatically sent as a response to the new byte.
- In transmission:
  - When STOPF = 1 and the first data byte must be sent. The content of the I2C\_TXDR register is sent if TXE = 0, 0xFF if not.
  - When a new byte must be sent and the I2C\_TXDR register has not been written yet, 0xFF is sent.

When an overrun or underrun error is detected, the OVR flag of the I2C\_ISR register is set and an interrupt is generated if the ERRIE bit of the I2C\_CR1 register is set.

### Packet error checking error (PECERR)

A PEC error is detected when the received PEC byte does not match the I2C\_PECR register content. A NACK is automatically sent after the wrong PEC reception.

When a PEC error is detected, the PECERR flag of the I2C\_ISR register is set and an interrupt is generated if the ERRIE bit of the I2C\_CR1 register is set.

### Timeout error (TIMEOUT)

A timeout error occurs for any of these conditions:

- TIDLE = 0 and SCL remains low for the time defined in the TIMEOUTA[11:0] bitfield: this is used to detect an SMBus timeout.
- TIDLE = 1 and both SDA and SCL remains high for the time defined in the TIMEOUTA [11:0] bitfield: this is used to detect a bus idle condition.
- Master cumulative clock low extend time reaches the time defined in the TIMEOUTB[11:0] bitfield (SMBus  $t_{\text{LOW:MEXT}}$  parameter).
- Slave cumulative clock low extend time reaches the time defined in the TIMEOUTB[11:0] bitfield (SMBus  $t_{\text{LOW:SEXT}}$  parameter).

When a timeout violation is detected in master mode, a STOP condition is automatically sent.

When a timeout violation is detected in slave mode, SDA and SCL lines are automatically released.

When a timeout error is detected, the TIMEOUT flag is set in the I2C\_ISR register and an interrupt is generated if the ERRIE bit of the I2C\_CR1 register is set.

### Alert (ALERT)

The ALERT flag is set when the I2C peripheral is configured as a host (SMBHEN = 1), the SMBALERT# signal detection is enabled (ALERTEN = 1), and a falling edge is detected on the SMBA pin. An interrupt is generated if the ERRIE bit of the I2C\_CR1 register is set.

## 39.5 I2C in low-power modes

**Table 244. Effect of low-power modes to I2C**

| Mode                   | Description                                                                                                                                                                                                                                                                                      |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Sleep                  | No effect. I2C interrupts cause the device to exit the Sleep mode.                                                                                                                                                                                                                               |
| Stop <sup>(1)(2)</sup> | The contents of I2C registers are kept.<br>– WUPEN = 1 and I2C is clocked by an internal oscillator (HSI16). The address recognition is functional. The I2C address match condition causes the device to exit the Stop mode.<br>– WUPEN = 0: the I2C must be disabled before entering Stop mode. |
| Standby                | The I2C peripheral is powered down. It must be reinitialized after exiting Standby mode.                                                                                                                                                                                                         |

1. Refer to [Section 39.3: I2C implementation](#) for information about the Stop modes supported by each instance. If the wake-up from a specific stop mode is not supported, the instance must be disabled before entering that specific Stop mode.
2. Only I2C3 supports wake-up from Stop 2 mode. The other I2C instances must be disabled before entering Stop 2 mode.

## 39.6 I2C interrupts

The following table gives the list of I2C interrupt requests.

**Table 245. I2C interrupt requests**

| Interrupt acronym | Interrupt event                    | Event flag | Enable control bit | Interrupt clear method             | Exit Sleep mode | Exit Stop modes    | Exit Standby modes |
|-------------------|------------------------------------|------------|--------------------|------------------------------------|-----------------|--------------------|--------------------|
| I2C_EV            | Receive buffer not empty           | RXNE       | RXIE               | Read I2C_RXDR register             | Yes             | No                 | No                 |
|                   | Transmit buffer interrupt status   | TXIS       | TXIE               | Write I2C_TXDR register            |                 |                    |                    |
|                   | STOP detection interrupt flag      | STOPF      | STOPIE             | Write STOPCF = 1                   |                 |                    |                    |
|                   | Transfer complete reload           | TCR        | TCIE               | Write I2C_CR2 with NBYTES[7:0] ≠ 0 |                 |                    |                    |
|                   | Transfer complete                  | TC         |                    | Write START = 1 or STOP = 1        |                 |                    |                    |
|                   | Address matched                    | ADDR       | ADDRIE             | Write ADDRCF = 1                   |                 | Yes <sup>(1)</sup> |                    |
|                   | NACK reception                     | NACKF      | NACKIE             | Write NACKCF = 1                   |                 | No                 |                    |
| I2C_ER            | Bus error                          | BERR       | ERRIE              | Write BERRCF = 1                   | Yes             | No                 | No                 |
|                   | Arbitration loss                   | ARLO       |                    | Write ARLOCF = 1                   |                 |                    |                    |
|                   | Overrun/underrun                   | OVR        |                    | Write OVRCF = 1                    |                 |                    |                    |
| I2C_ER            | PEC error                          | PECERR     | ERRIE              | Write PECERRCF = 1                 | Yes             | No                 | No                 |
|                   | Timeout/<br>t <sub>LOW</sub> error | TIMEOUT    |                    | Write<br>TIMEOUTCF = 1             |                 |                    |                    |
|                   | SMBus alert                        | ALERT      |                    | Write ALERTCF = 1                  |                 |                    |                    |

1. The ADDR match event can wake up the device from Stop mode only if the I2C instance supports the wake-up from Stop mode feature. Refer to [Section 39.3: I2C implementation](#).

## 39.7 I2C DMA requests

### Transmission using DMA

DMA (direct memory access) can be enabled for transmission by setting the TXDMAEN bit of the I2C\_CR1 register. Data is loaded from an SRAM area configured through the DMA peripheral (see [Section 11: Direct memory access controller \(DMA\)](#)) to the I2C\_TXDR register whenever the TXIS bit is set.

Only the data are transferred with DMA.

In master mode, the initialization, the slave address, direction, number of bytes and START bit are programmed by software (the transmitted slave address cannot be transferred with DMA). When all data are transferred using DMA, DMA must be initialized before setting the START bit. The end of transfer is managed with the NBYTES counter. Refer to [Master transmitter](#).

In slave mode:

- With NOSTRETCH = 0, when all data are transferred using DMA, DMA must be initialized before the address match event, or in ADDR interrupt subroutine, before clearing ADDR.
- With NOSTRETCH = 1, the DMA must be initialized before the address match event.

The PEC transfer is managed with the counter associated to the NBYTES[7:0] bitfield. Refer to [SMBus slave transmitter](#) and [SMBus master mode](#).

*Note:* If DMA is used for transmission, it is not required to set the TXIE bit.

### Reception using DMA

DMA (direct memory access) can be enabled for reception by setting the RXDMAEN bit of the I2C\_CR1 register. Data is loaded from the I2C\_RXDR register to an SRAM area configured through the DMA peripheral (refer to [Section 11: Direct memory access controller \(DMA\)](#)) whenever the RXNE bit is set. Only the data (including PEC) are transferred with DMA.

In master mode, the initialization, the slave address, direction, number of bytes and START bit are programmed by software. When all data are transferred using DMA, DMA must be initialized before setting the START bit. The end of transfer is managed with the NBYTES counter.

In slave mode with NOSTRETCH = 0, when all data are transferred using DMA, the DMA must be initialized before the address match event, or in the ADDR interrupt subroutine, before clearing the ADDR flag.

The PEC transfer is managed with the counter associated to the NBYTES[7:0] bitfield. Refer to [SMBus slave receiver](#) and [SMBus master receiver](#).

*Note:* If DMA is used for reception, it is not required to set the RXIE bit.

## 39.8 I2C debug modes

When the device enters debug mode (core halted), the SMBus timeout either continues working normally or stops, depending on the DBG\_I2Cx\_STOP bits in the DBG block.

## 39.9 I2C registers

Refer to [Section 1.2 on page 69](#) for the list of abbreviations used in register descriptions.

The registers are accessed by words (32-bit).

### 39.9.1 I2C control register 1 (I2C\_CR1)

Address offset: 0x00

Reset value: 0x0000 0000

Access: no wait states, except if a write access occurs while a write access is ongoing. In this case, wait states are inserted in the second write access, until the previous one is completed. The latency of the second write access can be up to  $2 \times \text{PCLK1} + 6 \times \text{I2CCLK}$ .

|             |             |      |            |          |      |      |      |           |             |            |            |            |           |               |     |

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **PECEN**: PEC enable

- 0: PEC calculation disabled
- 1: PEC calculation enabled

Bit 22 **ALERTEN**: SMBus alert enable

- 0: The SMBALERT# signal on SMBA pin is not supported in host mode (SMBHEN = 1). In device mode (SMBHEN = 0), the SMBA pin is released and the alert response address header is disabled (0001100x followed by NACK).
- 1: The SMBALERT# signal on SMBA pin is supported in host mode (SMBHEN = 1). In device mode (SMBHEN = 0), the SMBA pin is driven low and the alert response address header is enabled (0001100x followed by ACK).

*Note: When ALERTEN = 0, the SMBA pin can be used as a standard GPIO.*

Bit 21 **SMBDEN**: SMBus device default address enable

- 0: Device default address disabled. Address 0b1100001x is NACKed.
- 1: Device default address enabled. Address 0b1100001x is ACKed.

Bit 20 **SMBHEN**: SMBus host address enable

- 0: Host address disabled. Address 0b0001000x is NACKed.
- 1: Host address enabled. Address 0b0001000x is ACKed.

Bit 19 **GCEN**: General call enable

- 0: General call disabled. Address 0b00000000 is NACKed.
- 1: General call enabled. Address 0b00000000 is ACKed.

Bit 18 **WUPEN**: Wake-up from Stop mode enable

- 0: Wake-up from Stop mode disabled.
- 1: Wake-up from Stop mode enabled.

*Note: WUPEN can be set only when DNF[3:0] = 0000.*

Bit 17 **NOSTRETCH**: Clock stretching disable

This bit is used to disable clock stretching in slave mode. It must be kept cleared in master mode.

- 0: Clock stretching enabled
- 1: Clock stretching disabled

*Note: This bit can be programmed only when the I2C peripheral is disabled (PE = 0).*

Bit 16 **SBC**: Slave byte control

This bit is used to enable hardware byte control in slave mode.

- 0: Slave byte control disabled
- 1: Slave byte control enabled

Bit 15 **RXDMAEN**: DMA reception requests enable

- 0: DMA mode disabled for reception
- 1: DMA mode enabled for reception

Bit 14 **TXDMAEN**: DMA transmission requests enable

- 0: DMA mode disabled for transmission
- 1: DMA mode enabled for transmission

Bit 13 Reserved, must be kept at reset value.

Bit 12 **ANFOFF**: Analog noise filter OFF

- 0: Analog noise filter enabled
- 1: Analog noise filter disabled

*Note: This bit can be programmed only when the I2C peripheral is disabled (PE = 0).*

Bits 11:8 **DNF[3:0]**: Digital noise filter

These bits are used to configure the digital noise filter on SDA and SCL input. The digital filter, filters spikes with a length of up to  $DNF[3:0] * t_{I2CCLK}$

0000: Digital filter disabled

0001: Digital filter enabled and filtering capability up to one  $t_{I2CCLK}$

...

1111: digital filter enabled and filtering capability up to fifteen  $t_{I2CCLK}$

*Note: If the analog filter is enabled, the digital filter is added to it. This filter can be programmed only when the I2C peripheral is disabled (PE = 0).*

Bit 7 **ERRIE**: Error interrupts enable

- 0: Error detection interrupts disabled
- 1: Error detection interrupts enabled

*Note: Any of these errors generates an interrupt:*

- arbitration loss (ARLO)
- bus error detection (BERR)
- overrun/underrun (OVR)
- timeout detection (TIMEOUT)
- PEC error detection (PECERR)
- alert pin event detection (ALERT)

Bit 6 **TCIE**: Transfer complete interrupt enable

0: Transfer complete interrupt disabled

1: Transfer complete interrupt enabled

*Note: Any of these events generates an interrupt:*

*Transfer complete (TC)*

*Transfer complete reload (TCR)*

Bit 5 **STOPIE**: STOP detection interrupt enable

0: STOP detection (STOPF) interrupt disabled

1: STOP detection (STOPF) interrupt enabled

Bit 4 **NACKIE**: Not acknowledge received interrupt enable

0: Not acknowledge (NACKF) received interrupts disabled

1: Not acknowledge (NACKF) received interrupts enabled

Bit 3 **ADDRIE**: Address match interrupt enable (slave only)

0: Address match (ADDR) interrupts disabled

1: Address match (ADDR) interrupts enabled

Bit 2 **RXIE**: RX interrupt enable

0: Receive (RXNE) interrupt disabled

1: Receive (RXNE) interrupt enabled

Bit 1 **TXIE**: TX interrupt enable

0: Transmit (TXIS) interrupt disabled

1: Transmit (TXIS) interrupt enabled

Bit 0 **PE**: Peripheral enable

0: Peripheral disabled

1: Peripheral enabled

*Note: When PE = 0, the I2C SCL and SDA lines are released. Internal state machines and status bits are put back to their reset value. When cleared, PE must be kept low for at least three APB clock cycles.*

### 39.9.2 I2C control register 2 (I2C\_CR2)

Address offset: 0x04

Reset value: 0x0000 0000

Access: no wait states, except if a write access occurs while a write access is ongoing. In this case, wait states are inserted in the second write access until the previous one is completed. The latency of the second write access can be up to  $2 \times \text{PCLK1} + 6 \times \text{I2CCLK}$ .

|      |      |       |             |       |             |             |            |             |    |    |    |    |    |    |    |
|------|------|-------|-------------|-------|-------------|-------------|------------|-------------|----|----|----|----|----|----|----|

| Res. | Res. | Res.  | Res.        | Res.  | PEC<br>BYTE | AUTO<br>END | RE<br>LOAD | NBYTES[7:0] |    |    |    |    |    |    |    |
|      |      |       |             |       | rs          | rw          | rw         | rw          | rw | rw | rw | rw | rw | rw | rw |
| 15   | 14   | 13    | 12          | 11    | 10          | 9           | 8          | 7           | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| NACK | STOP | START | HEAD<br>10R | ADD10 | RD_<br>WRN  | SADD[9:0]   |            |             |    |    |    |    |    |    |    |
| rs   | rs   | rs    | rw          | rw    | rw          | rw          | rw         | rw          | rw | rw | rw | rw | rw | rw | rw |

Bits 31:27 Reserved, must be kept at reset value.

Bit 26 **PECBYTE**: Packet error checking byte

This bit is set by software, and cleared by hardware when the PEC is transferred, or when a STOP condition or an Address matched is received, also when PE = 0.

0: No PEC transfer

1: PEC transmission/reception is requested

*Note: Writing 0 to this bit has no effect.*

*This bit has no effect when RELOAD is set, and in slave mode when SBC = 0.*

Bit 25 **AUTOEND**: Automatic end mode (master mode)

This bit is set and cleared by software.

0: software end mode: TC flag is set when NBYTES data are transferred, stretching SCL low.

1: Automatic end mode: a STOP condition is automatically sent when NBYTES data are transferred.

*Note: This bit has no effect in slave mode or when the RELOAD bit is set.*

Bit 24 **RELOAD**: NBYTES reload mode

This bit is set and cleared by software.

0: The transfer is completed after the NBYTES data transfer (STOP or RESTART follows).

1: The transfer is not completed after the NBYTES data transfer (NBYTES is reloaded). TCR flag is set when NBYTES data are transferred, stretching SCL low.

Bits 23:16 **NBYTES[7:0]**: Number of bytes

The number of bytes to be transmitted/received is programmed there. This field is don't care in slave mode with SBC = 0.

*Note: Changing these bits when the START bit is set is not allowed.*

Bit 15 **NACK**: NACK generation (slave mode)

The bit is set by software, cleared by hardware when the NACK is sent, or when a STOP condition or an Address matched is received, or when PE = 0.

0: an ACK is sent after current received byte.

1: a NACK is sent after current received byte.

*Note: Writing 0 to this bit has no effect.*

*This bit is used only in slave mode: in master receiver mode, NACK is automatically generated after last byte preceding STOP or RESTART condition, whatever the NACK bit value.*

*When an overrun occurs in slave receiver NOSTRETCH mode, a NACK is automatically generated, whatever the NACK bit value.*

*When hardware PEC checking is enabled (PECBYTE = 1), the PEC acknowledge value does not depend on the NACK value.*

Bit 14 **STOP**: STOP condition generation

This bit only pertains to master mode. It is set by software and cleared by hardware when a STOP condition is detected or when PE = 0.

0: No STOP generation

1: STOP generation after current byte transfer

*Note: Writing 0 to this bit has no effect.*

**Bit 13 START:** START condition generation

This bit is set by software. It is cleared by hardware after the START condition followed by the address sequence is sent, by an arbitration loss, by a timeout error detection, or when PE = 0. It can also be cleared by software, by setting the ADDRCONF bit of the I2C\_ICR register.

0: No START generation

1: RESTART/START generation:

If the I2C is already in master mode with AUTOEND = 0, setting this bit generates a repeated START condition when RELOAD = 0, after the end of the NBYTES transfer.

Otherwise, setting this bit generates a START condition once the bus is free.

*Note: Writing 0 to this bit has no effect.*

*The START bit can be set even if the bus is BUSY or I2C is in slave mode.*

*This bit has no effect when RELOAD is set.*

**Bit 12 HEAD10R:** 10-bit address header only read direction (master receiver mode)

0: The master sends the complete 10-bit slave address read sequence: START + 2 bytes 10-bit address in write direction + RESTART + first seven bits of the 10-bit address in read direction.

1: The master sends only the first seven bits of the 10-bit address, followed by read direction.

*Note: Changing this bit when the START bit is set is not allowed.*

**Bit 11 ADD10:** 10-bit addressing mode (master mode)

0: The master operates in 7-bit addressing mode

1: The master operates in 10-bit addressing mode

*Note: Changing this bit when the START bit is set is not allowed.*

**Bit 10 RD\_WRN:** Transfer direction (master mode)

0: Master requests a write transfer

1: Master requests a read transfer

*Note: Changing this bit when the START bit is set is not allowed.*

**Bits 9:0 SADD[9:0]:** Slave address (master mode)

**Condition: In 7-bit addressing mode (ADD10 = 0):**

SADD[7:1] must be written with the 7-bit slave address to be sent. Bits SADD[9], SADD[8] and SADD[0] are don't care.

**Condition: In 10-bit addressing mode (ADD10 = 1):**

SADD[9:0] must be written with the 10-bit slave address to be sent.

*Note: Changing these bits when the START bit is set is not allowed.*

**39.9.3 I2C own address 1 register (I2C\_OAR1)**

Address offset: 0x08

Reset value: 0x0000 0000

Access: no wait states, except if a write access occurs while a write access is ongoing. In this case, wait states are inserted in the second write access until the previous one is completed. The latency of the second write access can be up to  $2 \times \text{PCLK1} + 6 \times \text{I2CCLK}$ .

|       |      |      |      |      |             |          |      |      |      |      |      |      |      |      |      |

| rw    |      |      |      |      | rw          | rw       | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   |

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **OA1EN**: Own address 1 enable

0: Own address 1 disabled. The received slave address OA1 is NACKed.

1: Own address 1 enabled. The received slave address OA1 is ACKed.

Bits 14:11 Reserved, must be kept at reset value.

Bit 10 **OA1MODE**: Own address 1 10-bit mode

0: Own address 1 is a 7-bit address.

1: Own address 1 is a 10-bit address.

*Note: This bit can be written only when OA1EN = 0.*

Bits 9:0 **OA1[9:0]**: Interface own slave address

7-bit addressing mode: OA1[7:1] contains the 7-bit own slave address. Bits OA1[9], OA1[8] and OA1[0] are don't care.

10-bit addressing mode: OA1[9:0] contains the 10-bit own slave address.

*Note: These bits can be written only when OA1EN = 0.*

### 39.9.4 I2C own address 2 register (I2C\_OAR2)

Address offset: 0x0C

Reset value: 0x0000 0000

Access: no wait states, except if a write access occurs while a write access is ongoing. In this case, wait states are inserted in the second write access, until the previous one is completed. The latency of the second write access can be up to  $2 \times \text{PCLK1} + 6 \times \text{I2CCLK}$ .

|       |      |      |      |      |             |      |      |          |      |      |      |      |      |      |      |

| 15    | 14   | 13   | 12   | 11   | 10          | 9    | 8    | 7        | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| OA2EN | Res. | Res. | Res. | Res. | OA2MSK[2:0] |      |      | OA2[7:1] |      |      |      |      |      |      | Res. |
| rw    |      |      |      |      | rw          | rw   | rw   | rw       | rw   | rw   | rw   | rw   | rw   | rw   |      |

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **OA2EN**: Own address 2 enable

0: Own address 2 disabled. The received slave address OA2 is NACKed.

1: Own address 2 enabled. The received slave address OA2 is ACKed.

Bits 14:11 Reserved, must be kept at reset value.

Bits 10:8 **OA2MSK[2:0]**: Own address 2 masks

000: No mask

001: OA2[1] is masked and don't care. Only OA2[7:2] are compared.

010: OA2[2:1] are masked and don't care. Only OA2[7:3] are compared.

011: OA2[3:1] are masked and don't care. Only OA2[7:4] are compared.

100: OA2[4:1] are masked and don't care. Only OA2[7:5] are compared.

101: OA2[5:1] are masked and don't care. Only OA2[7:6] are compared.

110: OA2[6:1] are masked and don't care. Only OA2[7] is compared.

111: OA2[7:1] are masked and don't care. No comparison is done, and all (except reserved) 7-bit received addresses are acknowledged.

*Note: These bits can be written only when OA2EN = 0.*

*As soon as OA2MSK ≠ 0, the reserved I2C addresses (0b0000xxx and 0b1111xxx) are not acknowledged, even if the comparison matches.*

Bits 7:1 **OA2[7:1]**: Interface address

7-bit addressing mode: 7-bit address

*Note: These bits can be written only when OA2EN = 0.*

Bit 0 Reserved, must be kept at reset value.

### 39.9.5 I2C timing register (I2C\_TIMINGR)

Address offset: 0x10

Reset value: 0x0000 0000

Access: no wait states

|            |    |    |    |      |      |      |      |             |    |    |    |             |    |    |    |
|------------|----|----|----|------|------|------|------|-------------|----|----|----|-------------|----|----|----|
| 31         | 30 | 29 | 28 | 27   | 26   | 25   | 24   | 23          | 22 | 21 | 20 | 19          | 18 | 17 | 16 |
| PRESC[3:0] |    |    |    | Res. | Res. | Res. | Res. | SCLDEL[3:0] |    |    |    | SDADEL[3:0] |    |    |    |
| rw         | rw | rw | rw |      |      |      |      | rw          | rw | rw | rw | rw          | rw | rw | rw |
| 15         | 14 | 13 | 12 | 11   | 10   | 9    | 8    | 7           | 6  | 5  | 4  | 3           | 2  | 1  | 0  |
| SCLH[7:0]  |    |    |    |      |      |      |      | SCLL[7:0]   |    |    |    |             |    |    |    |
| rw         | rw | rw | rw | rw   | rw   | rw   | rw   | rw          | rw | rw | rw | rw          | rw | rw | rw |

Bits 31:28 **PRESC[3:0]**: Timing prescaler

This field is used to prescale I2CCLK to generate the clock period  $t_{\text{PRESC}}$  used for data setup and hold counters (refer to section [I2C timings](#)), and for SCL high and low level counters (refer to section [I2C master initialization](#)).

$$t_{\text{PRESC}} = (\text{PRESC} + 1) \times t_{\text{I2CCLK}}$$

Bits 27:24 Reserved, must be kept at reset value.

Bits 23:20 **SCLDEL[3:0]**: Data setup time

This field is used to generate a delay  $t_{\text{SCLDEL}} = (\text{SCLDEL} + 1) \times t_{\text{PRESC}}$  between SDA edge and SCL rising edge. In master and in slave modes with NOSTRETCH = 0, the SCL line is stretched low during  $t_{\text{SCLDEL}}$ .

*Note:  $t_{\text{SCLDEL}}$  is used to generate  $t_{\text{SU:DAT}}$  timing.*

Bits 19:16 **SDADEL[3:0]**: Data hold time

This field is used to generate the delay  $t_{\text{SDADEL}}$  between SCL falling edge and SDA edge. In master and in slave modes with NOSTRETCH = 0, the SCL line is stretched low during  $t_{\text{SDADEL}}$ .

$$t_{\text{SDADEL}} = \text{SDADEL} \times t_{\text{PRESC}}$$

*Note: SDADEL is used to generate  $t_{\text{HD:DAT}}$  timing.*

Bits 15:8 **SCLH[7:0]**: SCL high period (master mode)

This field is used to generate the SCL high period in master mode.

$$t_{\text{SCLH}} = (\text{SCLH} + 1) \times t_{\text{PRESC}}$$

*Note: SCLH is also used to generate  $t_{\text{SU:STO}}$  and  $t_{\text{HD:STA}}$  timing.*

Bits 7:0 **SCLL[7:0]**: SCL low period (master mode)

This field is used to generate the SCL low period in master mode.

$$t_{\text{SCLL}} = (\text{SCLL} + 1) \times t_{\text{PRESC}}$$

*Note: SCLL is also used to generate  $t_{\text{BUF}}$  and  $t_{\text{SU:STA}}$  timings.*

*Note: This register must be configured when the I2C peripheral is disabled (PE = 0).*

*Note: The STM32CubeMX tool calculates and provides the I2C\_TIMINGR content in the I2C Configuration window.*

### 39.9.6 I2C timeout register (I2C\_TIMEOUTR)

Address offset: 0x14

Reset value: 0x0000 0000

Access: no wait states, except if a write access occurs while a write access is ongoing. In this case, wait states are inserted in the second write access until the previous one is completed. The latency of the second write access can be up to  $2 \times \text{PCLK1} + 6 \times \text{I2CCLK}$ .

|          |      |      |       |                |    |    |    |    |    |    |    |    |    |    |    |
|----------|------|------|-------|----------------|----|----|----|----|----|----|----|----|----|----|----|
| 31       | 30   | 29   | 28    | 27             | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| TEXTEN   | Res. | Res. | Res.  | TIMEOUTB[11:0] |    |    |    |    |    |    |    |    |    |    |    |
| rw       |      |      |       | rw             | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
| 15       | 14   | 13   | 12    | 11             | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| TIMOUTEN | Res. | Res. | TIDLE | TIMEOUTA[11:0] |    |    |    |    |    |    |    |    |    |    |    |
| rw       |      |      | rw    | rw             | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bit 31 **TEXTEN**: Extended clock timeout enable

0: Extended clock timeout detection is disabled

1: Extended clock timeout detection is enabled. When a cumulative SCL stretch for more than  $t_{\text{LOW:EXT}}$  is done by the I2C interface, a timeout error is detected (TIMEOUT = 1).

Bits 30:28 Reserved, must be kept at reset value.

Bits 27:16 **TIMEOUTB[11:0]**: Bus timeout B

This field is used to configure the cumulative clock extension timeout:

- Master mode: the master cumulative clock low extend time ( $t_{\text{LOW:MEXT}}$ ) is detected
- Slave mode: the slave cumulative clock low extend time ( $t_{\text{LOW:SEXT}}$ ) is detected

$$t_{\text{LOW:EXT}} = (\text{TIMEOUTB} + \text{TIDLE} = 01) \times 2048 \times t_{\text{I2CCLK}}$$

*Note: These bits can be written only when TEXTEN = 0.*

Bit 15 **TIMOUTEN**: Clock timeout enable

0: SCL timeout detection is disabled

1: SCL timeout detection is enabled. When SCL is low for more than  $t_{\text{TIMEOUT}}$  (TIDLE = 0) or high for more than  $t_{\text{IDLE}}$  (TIDLE = 1), a timeout error is detected (TIMEOUT = 1).

Bits 14:13 Reserved, must be kept at reset value.

Bit 12 **TIDLE**: Idle clock timeout detection

0: TIMEOUTA is used to detect SCL low timeout

1: TIMEOUTA is used to detect both SCL and SDA high timeout (bus idle condition)

*Note: This bit can be written only when TIMOUTEN = 0.*

Bits 11:0 **TIMEOUTA[11:0]**: Bus timeout A

This field is used to configure:

The SCL low timeout condition  $t_{\text{TIMEOUT}}$  when TIDLE = 0

$t_{\text{TIMEOUT}} = (\text{TIMEOUTA} + 1) \times 2048 \times t_{\text{I2CCLK}}$

The bus idle condition (both SCL and SDA high) when TIDLE = 1

$t_{\text{IDLE}} = (\text{TIMEOUTA} + 1) \times 4 \times t_{\text{I2CCLK}}$

*Note: These bits can be written only when TIMOUTEN = 0.*

### 39.9.7 I2C interrupt and status register (I2C\_ISR)

Address offset: 0x18

Reset value: 0x0000 0001

Access: no wait states

| 31   | 30   | 29    | 28       | 27      | 26   | 25   | 24   | 23           | 22 | 21    | 20    | 19   | 18   | 17   | 16  |

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:17 **ADDCODE[6:0]**: Address match code (slave mode)

These bits are updated with the received address when an address match event occurs (ADDR = 1). In the case of a 10-bit address, ADDCODE provides the 10-bit header followed by the two MSBs of the address.

Bit 16 **DIR**: Transfer direction (slave mode)

This flag is updated when an address match event occurs (ADDR = 1).

0: Write transfer, slave enters receiver mode.

1: Read transfer, slave enters transmitter mode.

Bit 15 **BUSY**: Bus busy

This flag indicates that a communication is in progress on the bus. It is set by hardware when a START condition is detected, and cleared by hardware when a STOP condition is detected, or when PE = 0.

Bit 14 Reserved, must be kept at reset value.

**Bit 13 ALERT:** SMBus alert

This flag is set by hardware when SMBHEN = 1 (SMBus host configuration), ALERTEN = 1 and an SMBALERT# event (falling edge) is detected on SMBA pin. It is cleared by software by setting the ALERTCF bit.

*Note: This bit is cleared by hardware when PE = 0.*

**Bit 12 TIMEOUT:** Timeout or  $t_{LOW}$  detection flag

This flag is set by hardware when a timeout or extended clock timeout occurred. It is cleared by software by setting the TIMEOUTCF bit.

*Note: This bit is cleared by hardware when PE = 0.*

**Bit 11 PECERR:** PEC error in reception

This flag is set by hardware when the received PEC does not match with the PEC register content. A NACK is automatically sent after the wrong PEC reception. It is cleared by software by setting the PECCF bit.

*Note: This bit is cleared by hardware when PE = 0.*

**Bit 10 OVR:** Overrun/underrun (slave mode)

This flag is set by hardware in slave mode with NOSTRETCH = 1, when an overrun/underrun error occurs. It is cleared by software by setting the OVRCF bit.

*Note: This bit is cleared by hardware when PE = 0.*

**Bit 9 ARLO:** Arbitration lost

This flag is set by hardware in case of arbitration loss. It is cleared by software by setting the ARLOCF bit.

*Note: This bit is cleared by hardware when PE = 0.*

**Bit 8 BERR:** Bus error

This flag is set by hardware when a misplaced START or STOP condition is detected whereas the peripheral is involved in the transfer. The flag is not set during the address phase in slave mode. It is cleared by software by setting the BERRCF bit.

*Note: This bit is cleared by hardware when PE = 0.*

**Bit 7 TCR:** Transfer complete reload

This flag is set by hardware when RELOAD = 1 and NBYTES data have been transferred. It is cleared by software when NBYTES is written to a non-zero value.

*Note: This bit is cleared by hardware when PE = 0.*

*This flag is only for master mode, or for slave mode when the SBC bit is set.*

**Bit 6 TC:** Transfer complete (master mode)

This flag is set by hardware when RELOAD = 0, AUTOEND = 0 and NBYTES data have been transferred. It is cleared by software when START bit or STOP bit is set.

*Note: This bit is cleared by hardware when PE = 0.*

**Bit 5 STOPF:** STOP detection flag

This flag is set by hardware when a STOP condition is detected on the bus and the peripheral is involved in this transfer:

- as a master, provided that the STOP condition is generated by the peripheral.
- as a slave, provided that the peripheral has been addressed previously during this transfer.

It is cleared by software by setting the STOPCF bit.

*Note: This bit is cleared by hardware when PE = 0.*

Bit 4 **NACKF**: Not acknowledge received flag

This flag is set by hardware when a NACK is received after a byte transmission. It is cleared by software by setting the NACKCF bit.

*Note: This bit is cleared by hardware when PE = 0.*

Bit 3 **ADDR**: Address matched (slave mode)

This bit is set by hardware as soon as the received slave address matched with one of the enabled slave addresses. It is cleared by software by setting ADDR CF bit.

*Note: This bit is cleared by hardware when PE = 0.*

Bit 2 **RXNE**: Receive data register not empty (receivers)

This bit is set by hardware when the received data is copied into the I2C\_RXDR register, and is ready to be read. It is cleared when I2C\_RXDR is read.

*Note: This bit is cleared by hardware when PE = 0.*

Bit 1 **TXIS**: Transmit interrupt status (transmitters)

This bit is set by hardware when the I2C\_TXDR register is empty and the data to be transmitted must be written in the I2C\_TXDR register. It is cleared when the next data to be sent is written in the I2C\_TXDR register.

This bit can be written to 1 by software only when NOSTRETCH = 1, to generate a TXIS event (interrupt if TXIE = 1 or DMA request if TXDMAEN = 1).

*Note: This bit is cleared by hardware when PE = 0.*

Bit 0 **TXE**: Transmit data register empty (transmitters)

This bit is set by hardware when the I2C\_TXDR register is empty. It is cleared when the next data to be sent is written in the I2C\_TXDR register.

This bit can be written to 1 by software in order to flush the transmit data register I2C\_TXDR.

*Note: This bit is set by hardware when PE = 0.*

### 39.9.8 I2C interrupt clear register (I2C\_ICR)

Address offset: 0x1C

Reset value: 0x0000 0000

Access: no wait states

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **ALERTCF**: Alert flag clear

Writing 1 to this bit clears the ALERT flag in the I2C\_ISR register.

Bit 12 **TIMEOUTCF**: Timeout detection flag clear

Writing 1 to this bit clears the TIMEOUT flag in the I2C\_ISR register.

Bit 11 **PECCF**: PEC error flag clear

Writing 1 to this bit clears the PECERR flag in the I2C\_ISR register.

Bit 10 **OVRCF**: Overrun/underrun flag clear

Writing 1 to this bit clears the OVR flag in the I2C\_ISR register.

Bit 9 **ARLOCF**: Arbitration lost flag clear

Writing 1 to this bit clears the ARLO flag in the I2C\_ISR register.

Bit 8 **BERRCF**: Bus error flag clear

Writing 1 to this bit clears the BERRF flag in the I2C\_ISR register.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **STOPCF**: STOP detection flag clear

Writing 1 to this bit clears the STOPF flag in the I2C\_ISR register.

Bit 4 **NACKCF**: Not acknowledge flag clear

Writing 1 to this bit clears the NACKF flag in I2C\_ISR register.

Bit 3 **ADDRCF**: Address matched flag clear

Writing 1 to this bit clears the ADDR flag in the I2C\_ISR register. Writing 1 to this bit also clears the START bit in the I2C\_CR2 register.

Bits 2:0 Reserved, must be kept at reset value.

### 39.9.9 I2C PEC register (I2C\_PECR)

Address offset: 0x20

Reset value: 0x0000 0000

Access: no wait states

Refer to [Section 2.2 on page 75](#) for the register boundary addresses.

## 40 Universal synchronous/asynchronous receiver transmitter (USART/UART)

### 40.1 Introduction

The universal synchronous asynchronous receiver transmitter (USART) offers a flexible means of Full-duplex data exchange with external equipment requiring an industry standard NRZ asynchronous serial data format. The USART offers a very wide range of baud rates using a programmable baud rate generator.

It supports synchronous one-way communication and half-duplex single-wire communication, as well as multiprocessor communications. It also supports the LIN (Local Interconnect Network), smartcard protocol and IrDA (Infrared Data Association) SIR ENDEC specifications and modem operations (CTS/RTS).

High speed data communication is possible by using the DMA (direct memory access) for multibuffer configuration.

### 40.2 USART main features

- Full-duplex asynchronous communications
- NRZ standard format (mark/space)
- Configurable oversampling method by 16 or 8 to give flexibility between speed and clock tolerance
- A common programmable transmit and receive baud rate of up to 10 Mbit/s when the clock frequency is 80 MHz and oversampling is by 8
- Dual clock domain allowing:
  - USART functionality and wake-up from Stop mode
  - Convenient baud rate programming independent from the PCLK reprogramming
- Auto baud rate detection
- Programmable data word length (7, 8 or 9 bits)
- Programmable data order with MSB-first or LSB-first shifting
- Configurable stop bits (1 or 2 stop bits)
- Synchronous mode and clock output for synchronous communications
- Single-wire half-duplex communications
- Continuous communications using DMA
- Received/transmitted bytes are buffered in reserved SRAM using centralized DMA
- Separate enable bits for transmitter and receiver
- Separate signal polarity control for transmission and reception
- Swappable Tx/Rx pin configuration
- Hardware flow control for modem and RS-485 transceiver

- Communication control/error detection flags
- Parity control:
  - Transmits parity bit
  - Checks parity of received data byte
- Fourteen interrupt sources with flags
- Multiprocessor communications
  - The USART enters mute mode if the address does not match.
- Wake-up from mute mode (by idle line detection or address mark detection)

### 40.3 USART extended features

- LIN master synchronous break send capability and LIN slave break detection capability
  - 13-bit break generation and 10/11-bit break detection when USART is hardware configured for LIN
- IrDA SIR encoder decoder supporting 3/16 bit duration for normal mode
- Smartcard mode
  - Supports the T=0 and T=1 asynchronous protocols for smartcards as defined in the ISO/IEC 7816-3 standard
  - 0.5 and 1.5 stop bits for smartcard operation
- Support for ModBus communication
  - Timeout feature
  - CR/LF character recognition

## 40.4 USART implementation

The STM32L47x/L48x/L49x/L4Ax devices embed 3 USARTs, 2 UARTs and 1 LPUART. The [Table 247](#) describes the features supported by each peripheral.

**Table 247. STM32L47x/L48x/L49x/L4Ax USART/UART/LPUART features**

| USART modes/features <sup>(1)</sup>          | USART1                          | USART2 | USART3 | UART4 | UART5 | LPUART1 |

| USART/UART/LPUART data length                | 7 <sup>(2)</sup> , 8 and 9 bits |        |        |       |       |         |

1. X = supported.

2. In 7-bit data length mode, smartcard mode, LIN master mode and Auto baud rate (0x7F and 0x55 frames) detection are not supported.

**Note:** *In the STM32L49x/L4Ax devices only, bit TCBGT in USART\_ISR, bit TCBGTIE in USART\_CR3 and bit TCBGTCF in USART\_ICR are available, allowing detecting the character end of transmission without waiting until the end of the guard time completion.*

## 40.5 USART functional description

Any USART bidirectional communication requires a minimum of two pins: Receive data In (RX) and Transmit data Out (TX):

- **RX:** Receive data Input.

This is the serial data input. Oversampling techniques are used for data recovery by discriminating between valid incoming data and noise.

- **TX:** Transmit data Output.

When the transmitter is disabled, the output pin returns to its I/O port configuration. When the transmitter is enabled and nothing is to be transmitted, the TX pin is at high level. In single-wire and smartcard modes, this I/O is used to transmit and receive the data.

Serial data are transmitted and received through these pins in normal USART mode. The frames are comprised of:

- An Idle Line prior to transmission or reception
- A start bit
- A data word (7, 8 or 9 bits) least significant bit first
- 0.5, 1, 1.5, 2 stop bits indicating that the frame is complete
- The USART interface uses a baud rate generator
- A status register (USART\_ISR)
- Receive and transmit data registers (USART\_RDR, USART\_TDR)
- A baud rate register (USART\_BRR)
- A guard-time register (USART\_GTPR) in case of smartcard mode.

Refer to [Section 40.8: USART registers on page 1366](#) for the definitions of each bit.

The following pin is required to interface in synchronous mode and smartcard mode:

- **CK:** Clock output. This pin outputs the transmitter data clock for synchronous transmission corresponding to SPI master mode (no clock pulses on start bit and stop bit, and a software option to send a clock pulse on the last data bit). In parallel, data can be received synchronously on RX. This can be used to control peripherals that have shift registers. The clock phase and polarity are software programmable. In smartcard mode, CK output can provide the clock to the smartcard.

The following pins are required in RS232 hardware flow control mode:

- **CTS:** Clear To Send blocks the data transmission at the end of the current transfer (when high)
- **RTS:** Request to send indicates that the USART is ready to receive data (when low).

The following pin is required in RS485 hardware control mode:

- **DE:** Driver Enable activates the transmission mode of the external transceiver.

*Note:* **DE** and **RTS** share the same pin.

Figure 420. USART block diagram

1. For details on coding USARTDIV in the USART\_BRR register, refer to [Section 40.5.4: USART baud rate generation](#).
2.  $f_{CK}$  can be  $f_{LSE}$ ,  $f_{HSI}$ ,  $f_{PCLK}$ ,  $f_{SYS}$ .

### 40.5.1 USART character description

The word length can be selected as being either 7 or 8 or 9 bits by programming the M[1:0] bits in the USART\_CR1 register (see [Figure 421](#)).

- 7-bit character length: M[1:0] = 10
- 8-bit character length: M[1:0] = 00
- 9-bit character length: M[1:0] = 01

*Note:* The 7-bit mode is supported only on some USARTs. In addition, not all modes are supported in 7-bit data length mode. Refer to [Section 40.4: USART implementation](#) for additional information.

By default, the signal (TX or RX) is in low state during the start bit. It is in high state during the stop bit.

These values can be inverted, separately for each signal, through polarity configuration control.

An **Idle character** is interpreted as an entire frame of “1”s (the number of “1”s includes the number of stop bits).

A **Break character** is interpreted on receiving “0”s for a frame period. At the end of the break frame, the transmitter inserts 2 stop bits.

Transmission and reception are driven by a common baud rate generator, the clock for each is generated when the enable bit is set respectively for the transmitter and receiver.

The details of each block is given below.

Figure 421. Word length programming

## 40.5.2 USART transmitter

The transmitter can send data words of either 7, 8 or 9 bits depending on the M bits status. The Transmit Enable bit (TE) must be set in order to activate the transmitter function. The data in the transmit shift register is output on the TX pin and the corresponding clock pulses are output on the CK pin.

### Character transmission

During an USART transmission, data shifts out least significant bit first (default configuration) on the TX pin. In this mode, the USART\_TDR register consists of a buffer (TDR) between the internal bus and the transmit shift register (see [Figure 420](#)).

Every character is preceded by a start bit which is a logic level low for one bit period. The character is terminated by a configurable number of stop bits.

The following stop bits are supported by USART: 0.5, 1, 1.5 and 2 stop bits.

*Note: The TE bit must be set before writing the data to be transmitted to the USART\_TDR. The TE bit should not be reset during transmission of data. Resetting the TE bit during the transmission will corrupt the data on the TX pin as the baud rate counters will get frozen. The current data being transmitted is lost. An idle frame is sent after the TE bit is enabled.*

### Configurable stop bits

The number of stop bits to be transmitted with every character can be programmed in Control register 2, bits 13,12.

- **1 stop bit:** This is the default value of number of stop bits.
- **2 stop bits:** This is supported by normal USART, single-wire and modem modes.
- **1.5 stop bits:** To be used in smartcard mode.
- **0.5 stop bit:** To be used when receiving data in smartcard mode.

An idle frame transmission will include the stop bits.

A break transmission is 10 low bits (when M[1:0] = 00) or 11 low bits (when M[1:0] = 01) or 9 low bits (when M[1:0] = 10) followed by 2 stop bits (see [Figure 422](#)). It is not possible to transmit long breaks (break of length greater than 9/10/11 low bits).

Figure 422. Configurable stop bits

### Character transmission procedure

1. Program the M bits in USART\_CR1 to define the word length.
2. Select the desired baud rate using the USART\_BRR register.
3. Program the number of stop bits in USART\_CR2.
4. Enable the USART by writing the UE bit in USART\_CR1 register to 1.
5. Select DMA enable (DMAT) in USART\_CR3 if multibuffer communication is to take place. Configure the DMA register as explained in multibuffer communication.
6. Set the TE bit in USART\_CR1 to send an idle frame as first transmission.
7. Write the data to send in the USART\_TDR register (this clears the TXE bit). Repeat this for each data to be transmitted in case of single buffer.
8. After writing the last data into the USART\_TDR register, wait until TC=1. This indicates that the transmission of the last frame is complete. This is required for instance when the USART is disabled or enters the Halt mode to avoid corrupting the last transmission.

### Single byte communication

Clearing the TXE bit is always performed by a write to the transmit data register.

The TXE bit is set by hardware and it indicates:

- The data has been moved from the USART\_TDR register to the shift register and the data transmission has started.
- The USART\_TDR register is empty.
- The next data can be written in the USART\_TDR register without overwriting the previous data.

This flag generates an interrupt if the TXEIE bit is set.

When a transmission is taking place, a write instruction to the USART\_TDR register stores the data in the TDR register; next, the data is copied in the shift register at the end of the currently ongoing transmission.

When no transmission is taking place, a write instruction to the USART\_TDR register places the data in the shift register, the data transmission starts, and the TXE bit is set.

If a frame is transmitted (after the stop bit) and the TXE bit is set, the TC bit goes high. An interrupt is generated if the TCIE bit is set in the USART\_CR1 register.

After writing the last data in the USART\_TDR register, it is mandatory to wait for TC=1 before disabling the USART or causing the microcontroller to enter the low-power mode (see [Figure 423: TC/TXE behavior when transmitting](#)).

**Figure 423. TC/TXE behavior when transmitting**

### Break characters

Setting the SBKRQ bit transmits a break character. The break frame length depends on the M bits (see [Figure 421](#)).

If a '1' is written to the SBKRQ bit, a break character is sent on the TX line after completing the current character transmission. The SBKF bit is set by the write operation and it is reset by hardware when the break character is completed (during the stop bits after the break character). The USART inserts a logic 1 signal (STOP) for the duration of 2 bits at the end of the break frame to guarantee the recognition of the start bit of the next frame.

In the case the application needs to send the break character following all previously inserted data, including the ones not yet transmitted, the software should wait for the TXE flag assertion before setting the SBKRQ bit.

### Idle characters

Setting the TE bit drives the USART to send an idle frame before the first data frame.

## 40.5.3 USART receiver

The USART can receive data words of either 7, 8 or 9 bits depending on the M bits in the USART\_CR1 register.

### Start bit detection

The start bit detection sequence is the same when oversampling by 16 or by 8.

In the USART, the start bit is detected when a specific sequence of samples is recognized. This sequence is: 1 1 1 0 X 0 X 0X 0X 0 X 0X 0.

**Figure 424. Start bit detection when oversampling by 16 or 8**

**Note:** If the sequence is not complete, the start bit detection aborts and the receiver returns to the idle state (no flag is set), where it waits for a falling edge.

The start bit is confirmed (RXNE flag set, interrupt generated if RXNEIE=1) if the 3 sampled bits are at 0 (first sampling on the 3rd, 5th and 7th bits finds the 3 bits at 0 and second sampling on the 8th, 9th and 10th bits also finds the 3 bits at 0).

The start bit is validated (RXNE flag set, interrupt generated if RXNEIE=1) but the NF noise flag is set if,

- a) for both samplings, 2 out of the 3 sampled bits are at 0 (sampling on the 3rd, 5th and 7th bits and sampling on the 8th, 9th and 10th bits)
- or
- b) for one of the samplings (sampling on the 3rd, 5th and 7th bits or sampling on the 8th, 9th and 10th bits), 2 out of the 3 bits are found at 0.

If neither conditions a. or b. are met, the start detection aborts and the receiver returns to the idle state (no flag is set).

## Character reception

During an USART reception, data shifts in least significant bit first (default configuration) through the RX pin. In this mode, the USART\_RDR register consists of a buffer (RDR) between the internal bus and the receive shift register.

### Character reception procedure

1. Program the M bits in USART\_CR1 to define the word length.
2. Select the desired baud rate using the baud rate register USART\_BRR
3. Program the number of stop bits in USART\_CR2.
4. Enable the USART by writing the UE bit in USART\_CR1 register to 1.
5. Select DMA enable (DMAR) in USART\_CR3 if multibuffer communication is to take place. Configure the DMA register as explained in multibuffer communication.
6. Set the RE bit USART\_CR1. This enables the receiver which begins searching for a start bit.

When a character is received:

- The RXNE bit is set to indicate that the content of the shift register is transferred to the RDR. In other words, data has been received and can be read (as well as its associated error flags).
- An interrupt is generated if the RXNEIE bit is set.
- The error flags can be set if a frame error, noise or an overrun error has been detected during reception. PE flag can also be set with RXNE.
- In multibuffer, RXNE is set after every byte received and is cleared by the DMA read of the Receive data Register.
- In single buffer mode, clearing the RXNE bit is performed by a software read to the USART\_RDR register. The RXNE flag can also be cleared by writing 1 to the RXFRQ in the USART\_RQR register. The RXNE bit must be cleared before the end of the reception of the next character to avoid an overrun error.

### Break character

When a break character is received, the USART handles it as a framing error.

### Idle character

When an idle frame is detected, there is the same procedure as for a received data character plus an interrupt if the IDLEIE bit is set.

### Overrun error

An overrun error occurs when a character is received when RXNE has not been reset. Data can not be transferred from the shift register to the RDR register until the RXNE bit is cleared.

The RXNE flag is set after every byte received. An overrun error occurs if RXNE flag is set when the next data is received or the previous DMA request has not been serviced. When an overrun error occurs:

- The ORE bit is set.
- The RDR content will not be lost. The previous data is available when a read to USART\_RDR is performed.
- The shift register are overwritten. After that point, any data received during overrun is lost.
- An interrupt is generated if either the RXNEIE bit is set or EIE bit is set.
- The ORE bit is reset by setting the ORECF bit in the ICR register.

*Note: The ORE bit, when set, indicates that at least 1 datum has been lost. There are two possibilities:*

- if RXNE=1, then the last valid data is stored in the receive register RDR and can be read,
- if RXNE=0, then it means that the last valid data has already been read and thus there is nothing to be read in the RDR. This case can occur when the last valid data is read in the RDR at the same time as the new (and lost) data is received.

### Selecting the clock source and the proper oversampling method

The choice of the clock source is done through the Clock Control system (see Section Reset and clock control (RCC)). The clock source must be chosen before enabling the USART (by setting the UE bit).

The choice of the clock source must be done according to two criteria:

- Possible use of the USART in low-power mode
- Communication speed.

The clock source frequency is  $f_{CK}$ .

When the dual clock domain with the wake-up from Stop mode is supported, the clock source can be one of the following sources: PCLK (default), LSE, HSI16 or SYSCLK. Otherwise, the USART clock source is PCLK.

Choosing LSE or HSI16 as clock source may allow the USART to receive data while the MCU is in low-power mode. Depending on the received data and wake-up mode selection, the USART wakes up the MCU, when needed, in order to transfer the received data by software reading the USART\_RDR register or by DMA.

For the other clock sources, the system must be active in order to allow USART communication.

The communication speed range (specially the maximum communication speed) is also determined by the clock source.

The receiver implements different user-configurable oversampling techniques for data recovery by discriminating between valid incoming data and noise. This allows a trade-off between the maximum communication speed and noise/clock inaccuracy immunity.

The oversampling method can be selected by programming the OVER8 bit in the USART\_CR1 register and can be either 16 or 8 times the baud rate clock ([Figure 425](#) and [Figure 426](#)).

Depending on the application:

- Select oversampling by 8 (OVER8=1) to achieve higher speed (up to  $f_{CK}/8$ ). In this case the maximum receiver tolerance to clock deviation is reduced (refer to [Section 40.5.5: Tolerance of the USART receiver to clock deviation on page 1339](#))
- Select oversampling by 16 (OVER8=0) to increase the tolerance of the receiver to clock deviations. In this case, the maximum speed is limited to maximum  $f_{CK}/16$  where  $f_{CK}$  is the clock source frequency.

Programming the ONEBIT bit in the USART\_CR3 register selects the method used to evaluate the logic level. There are two options:

- The majority vote of the three samples in the center of the received bit. In this case, when the 3 samples used for the majority vote are not equal, the NF bit is set
- A single sample in the center of the received bit

Depending on the application:

- select the three samples' majority vote method (ONEBIT=0) when operating in a noisy environment and reject the data when a noise is detected (refer to [Figure 248](#)) because this indicates that a glitch occurred during the sampling.
- select the single sample method (ONEBIT=1) when the line is noise-free to increase the receiver's tolerance to clock deviations (see [Section 40.5.5: Tolerance of the USART receiver to clock deviation on page 1339](#)). In this case the NF bit will never be set.

When noise is detected in a frame:

- The NF bit is set at the rising edge of the RXNE bit.
- The invalid data is transferred from the Shift register to the USART\_RDR register.
- No interrupt is generated in case of single byte communication. However this bit rises at the same time as the RXNE bit which itself generates an interrupt. In case of multibuffer communication an interrupt is issued if the EIE bit is set in the USART\_CR3 register.

The NF bit is reset by setting NCF bit in ICR register.

*Note: Oversampling by 8 is not available in LIN, smartcard and IrDA modes. In those modes, the OVER8 bit is forced to '0' by hardware.*

Figure 425. Data sampling when oversampling by 16

Figure 426. Data sampling when oversampling by 8

Table 248. Noise detection from sampled data

| Sampled value | NE status | Received bit value |
|---------------|-----------|--------------------|
| 000           | 0         | 0                  |
| 001           | 1         | 0                  |
| 010           | 1         | 0                  |
| 011           | 1         | 1                  |
| 100           | 1         | 0                  |
| 101           | 1         | 1                  |
| 110           | 1         | 1                  |
| 111           | 0         | 1                  |

## Framing error

A framing error is detected when the stop bit is not recognized on reception at the expected time, following either a de-synchronization or excessive noise.

When the framing error is detected:

- The FE bit is set by hardware
- The invalid data is transferred from the Shift register to the USART\_RDR register.
- No interrupt is generated in case of single byte communication. However this bit rises at the same time as the RXNE bit which itself generates an interrupt. In case of multibuffer communication an interrupt is issued if the EIE bit is set in the USART\_CR3 register.

The FE bit is reset by writing 1 to the FECF in the USART\_ICR register.

## Configurable stop bits during reception

The number of stop bits to be received can be configured through the control bits of Control Register 2 - it can be either 1 or 2 in normal mode and 0.5 or 1.5 in smartcard mode.

- **0.5 stop bit (reception in smartcard mode):** *No sampling is done for 0.5 stop bit. As a consequence, no framing error and no break frame can be detected when 0.5 stop bit is selected.*
- **1 stop bit:** Sampling for 1 stop Bit is done on the 8th, 9th and 10th samples.
- **1.5 stop bits (smartcard mode):** When transmitting in smartcard mode, the device must check that the data is correctly sent. Thus the receiver block must be enabled (RE =1 in the USART\_CR1 register) and the stop bit is checked to test if the smartcard has detected a parity error. In the event of a parity error, the smartcard forces the data signal low during the sampling - NACK signal-, which is flagged as a framing error. Then, the FE flag is set with the RXNE at the end of the 1.5 stop bits. Sampling for 1.5 stop bits is done on the 16th, 17th and 18th samples (1 baud clock period after the beginning of the stop bit). The 1.5 stop bits can be decomposed into 2 parts: one 0.5 baud clock period during which nothing happens, followed by 1 normal stop bit period during which sampling occurs halfway through. Refer to [Section 40.5.13: USART smartcard mode on page 1350](#) for more details.
- **2 stop bits:** Sampling for 2 stop bits is done on the 8th, 9th and 10th samples of the first stop bit. If a framing error is detected during the first stop bit the framing error flag is set. The second stop bit is not checked for framing error. The RXNE flag is set at the end of the first stop bit.

#### 40.5.4 USART baud rate generation

The baud rate for the receiver and transmitter (Rx and Tx) are both set to the same value as programmed in the USART\_BRR register.

##### Equation 1: Baud rate for standard USART (SPI mode included) (OVER8 = 0 or 1)

In case of oversampling by 16, the equation is:

$$\text{Tx/Rx baud} = \frac{f_{\text{CK}}}{\text{USARTDIV}}$$

In case of oversampling by 8, the equation is:

$$\text{Tx/Rx baud} = \frac{2 \times f_{\text{CK}}}{\text{USARTDIV}}$$

##### Equation 2: Baud rate in smartcard, LIN and IrDA modes (OVER8 = 0)

In smartcard, LIN and IrDA modes, only oversampling by 16 is supported:

$$\text{Tx/Rx baud} = \frac{f_{\text{CK}}}{\text{USARTDIV}}$$

USARTDIV is an unsigned fixed point number that is coded on the USART\_BRR register.

- When OVER8 = 0, BRR = USARTDIV.
- When OVER8 = 1
  - BRR[2:0] = USARTDIV[3:0] shifted 1 bit to the right.
  - BRR[3] must be kept cleared.
  - BRR[15:4] = USARTDIV[15:4]

*Note:* The baud counters are updated to the new value in the baud registers after a write operation to USART\_BRR. Hence the baud rate register value should not be changed during communication.

*In case of oversampling by 16 or 8, USARTDIV must be greater than or equal to 16d.*

#### How to derive USARTDIV from USART\_BRR register values

##### Example 1

To obtain 9600 baud with  $f_{\text{CK}} = 8 \text{ MHz}$ .

- In case of oversampling by 16:
  - USARTDIV =  $8\,000\,000/9600$
  - BRR = USARTDIV = 0d833 = 0x341
- In case of oversampling by 8:
  - USARTDIV =  $2 * 8\,000\,000/9600$
  - USARTDIV = 1666,66 (0d1667 = 0x683)
  - BRR[3:0] = 0x3 >> 1 = 0x1
  - BRR = 0x681

**Example 2**

To obtain 921.6 kbaud with  $f_{CK} = 48$  MHz.

- In case of oversampling by 16:  
 $USARTDIV = 48\,000\,000/921\,600$   
 $BRR = USARTDIV = 52d = 34h$
- In case of oversampling by 8:  
 $USARTDIV = 2 * 48\,000\,000/921\,600$   
 $USARTDIV = 104$  (104d = 68h)  
 $BRR[3:0] = USARTDIV[3:0] >> 1 = 8h >> 1 = 4h$   
 $BRR = 0x64$

**Table 249. Error calculation for programmed baud rates at  $f_{CK} = 72$  MHz in both cases of oversampling by 16 or by 8<sup>(1)</sup>**

| Baud rate |            | Oversampling by 16 (OVER8 = 0) |        |                                                                 | Oversampling by 8 (OVER8 = 1) |        |         |
|-----------|------------|--------------------------------|--------|-----------------------------------------------------------------|-------------------------------|--------|---------|
| S.No      | Desired    | Actual                         | BRR    | % Error =<br>(Calculated -<br>Desired)B.Rate/<br>Desired B.Rate | Actual                        | BRR    | % Error |

| 16        | 9MBps      | N.A                            | N.A    | N.A                                                             | 9MBps                         | 0x10   | 0       |

1. The lower the CPU clock the lower the accuracy for a particular baud rate. The upper limit of the achievable baud rate can be fixed with these data.

### 40.5.5 Tolerance of the USART receiver to clock deviation

The asynchronous receiver of the USART works correctly only if the total clock system deviation is less than the tolerance of the USART receiver. The causes which contribute to the total deviation are:

- DTRA: Deviation due to the transmitter error (which also includes the deviation of the transmitter's local oscillator)
- DQUANT: Error due to the baud rate quantization of the receiver
- DREC: Deviation of the receiver's local oscillator
- DTCL: Deviation due to the transmission line (generally due to the transceivers which can introduce an asymmetry between the low-to-high transition timing and the high-to-low transition timing)

$$DTRA + DQUANT + DREC + DTCL + DWU < \text{USART receiver's tolerance}$$

where

DWU is the error due to sampling point deviation when the wake-up from Stop mode is used.

when M[1:0] = 01:

$$DWU = \frac{t_{WUUSART}}{11 \times T_{bit}}$$

when M[1:0] = 00:

$$DWU = \frac{t_{WUUSART}}{10 \times T_{bit}}$$

when M[1:0] = 10:

$$DWU = \frac{t_{WUUSART}}{9 \times T_{bit}}$$

$t_{WUUSART}$  is the time between:

- The detection of start bit falling edge
- The instant when clock (requested by the peripheral) is ready and reaching the peripheral and regulator is ready.

The USART receiver can receive data correctly at up to the maximum tolerated deviation specified in [Table 250](#) and [Table 251](#) depending on the following choices:

- 9-, 10- or 11-bit character length defined by the M bits in the USART\_CR1 register
- Oversampling by 8 or 16 defined by the OVER8 bit in the USART\_CR1 register
- Bits BRR[3:0] of USART\_BRR register are equal to or different from 0000.
- Use of 1 bit or 3 bits to sample the data, depending on the value of the ONEBIT bit in the USART\_CR3 register.

Table 250. Tolerance of the USART receiver when BRR [3:0] = 0000

| M bits | OVER8 bit = 0 |          | OVER8 bit = 1 |          |
|--------|---------------|----------|---------------|----------|
|        | ONEBIT=0      | ONEBIT=1 | ONEBIT=0      | ONEBIT=1 |
| 00     | 3.75%         | 4.375%   | 2.50%         | 3.75%    |
| 01     | 3.41%         | 3.97%    | 2.27%         | 3.41%    |
| 10     | 4.16%         | 4.86%    | 2.77%         | 4.16%    |

Table 251. Tolerance of the USART receiver when BRR [3:0] is different from 0000

| M bits | OVER8 bit = 0 |          | OVER8 bit = 1 |          |
|--------|---------------|----------|---------------|----------|
|        | ONEBIT=0      | ONEBIT=1 | ONEBIT=0      | ONEBIT=1 |
| 00     | 3.33%         | 3.88%    | 2%            | 3%       |
| 01     | 3.03%         | 3.53%    | 1.82%         | 2.73%    |
| 10     | 3.7%          | 4.31%    | 2.22%         | 3.33%    |

*Note:* The data specified in [Table 250](#) and [Table 251](#) may slightly differ in the special case when the received frames contain some Idle frames of exactly 10-bit durations when M bits = 00 (11-bit durations when M bits = 01 or 9-bit durations when M bits = 10).

#### 40.5.6 USART auto baud rate detection

The USART is able to detect and automatically set the USART\_BRR register value based on the reception of one character. Automatic baud rate detection is useful under two circumstances:

- The communication speed of the system is not known in advance
- The system is using a relatively low accuracy clock source and this mechanism allows the correct baud rate to be obtained without measuring the clock deviation.

The clock source frequency must be compatible with the expected communication speed (when oversampling by 16, the baud rate is between  $f_{CK}/65535$  and  $f_{CK}/16$ . when oversampling by 8, the baud rate is between  $f_{CK}/65535$  and  $f_{CK}/8$ ).

Before activating the auto baud rate detection, the auto baud rate detection mode must be chosen. There are various modes based on different character patterns.

They can be chosen through the ABRMOD[1:0] field in the USART\_CR2 register. In these auto baud rate modes, the baud rate is measured several times during the synchronization data reception and each measurement is compared to the previous one.

These modes are:

- **Mode 0:** Any character starting with a bit at 1. In this case the USART measures the duration of the Start bit (falling edge to rising edge).
- **Mode 1:** Any character starting with a 10xx bit pattern. In this case, the USART measures the duration of the Start and of the 1st data bit. The measurement is done falling edge to falling edge, ensuring better accuracy in the case of slow signal slopes.
- **Mode 2:** A 0x7F character frame (it may be a 0x7F character in LSB first mode or a 0xFE in MSB first mode). In this case, the baud rate is updated first at the end of the

start bit (BRs), then at the end of bit 6 (based on the measurement done from falling edge to falling edge: BR6). Bit 0 to bit 6 are sampled at BRs while further bits of the character are sampled at BR6.

- **Mode 3:** A 0x55 character frame. In this case, the baud rate is updated first at the end of the start bit (BRs), then at the end of bit 0 (based on the measurement done from falling edge to falling edge: BR0), and finally at the end of bit 6 (BR6). Bit 0 is sampled at BRs, bit 1 to bit 6 are sampled at BR0, and further bits of the character are sampled at BR6.

In parallel, another check is performed for each intermediate transition of RX line. An error is generated if the transitions on RX are not sufficiently synchronized with the receiver (the receiver being based on the baud rate calculated on bit 0).

Prior to activating auto baud rate detection, the USART\_BRR register must be initialized by writing a non-zero baud rate value.

The automatic baud rate detection is activated by setting the ABREN bit in the USART\_CR2 register. The USART will then wait for the first character on the RX line. The auto baud rate operation completion is indicated by the setting of the ABRF flag in the USART\_ISR register. If the line is noisy, the correct baud rate detection cannot be guaranteed. In this case the BRR value may be corrupted and the ABRE error flag is set. This also happens if the communication speed is not compatible with the automatic baud rate detection range (bit duration not between 16 and 65536 clock periods (oversampling by 16) and not between 8 and 65536 clock periods (oversampling by 8)).

The RXNE interrupt will signal the end of the operation.

At any later time, the auto baud rate detection may be relaunched by resetting the ABRF flag (by writing a 0).

*Note: If the USART is disabled (UE=0) during an auto baud rate operation, the BRR value may be corrupted.*

## 40.5.7 Multiprocessor communication using USART

In multiprocessor communication, the following bits are to be kept cleared:

- LINEN bit in the USART\_CR2 register,
- HDSEL, IREN and SCEN bits in the USART\_CR3 register.

It is possible to perform multiprocessor communication with the USART (with several USARTs connected in a network). For instance one of the USARTs can be the master, its TX output connected to the RX inputs of the other USARTs. The others are slaves, their respective TX outputs are logically ANDed together and connected to the RX input of the master.

In multiprocessor configurations it is often desirable that only the intended message recipient should actively receive the full message contents, thus reducing redundant USART service overhead for all non addressed receivers.

The non addressed devices may be placed in mute mode by means of the muting function. In order to use the mute mode feature, the MME bit must be set in the USART\_CR1 register.

In mute mode:

- None of the reception status bits can be set.
- All the receive interrupts are inhibited.
- The RWU bit in USART\_ISR register is set to 1. RWU can be controlled automatically by hardware or by software, through the MMRQ bit in the USART\_RQR register, under certain conditions.

The USART can enter or exit from mute mode using one of two methods, depending on the WAKE bit in the USART\_CR1 register:

- Idle Line detection if the WAKE bit is reset,
- Address Mark detection if the WAKE bit is set.

#### Idle line detection (WAKE=0)

The USART enters mute mode when the MMRQ bit is written to 1 and the RWU is automatically set.

It wakes up when an Idle frame is detected. Then the RWU bit is cleared by hardware but the IDLE bit is not set in the USART\_ISR register. An example of mute mode behavior using Idle line detection is given in [Figure 427](#).

**Figure 427. Mute mode using Idle line detection**

**Note:** *If the MMRQ is set while the IDLE character has already elapsed, mute mode will not be entered (RWU is not set).*

*If the USART is activated while the line is idle, the idle state is detected after the duration of one IDLE frame (not only after the reception of one character frame).*

#### 4-bit/7-bit address mark detection (WAKE=1)

In this mode, bytes are recognized as addresses if their MSB is a '1' otherwise they are considered as data. In an address byte, the address of the targeted receiver is put in the 4 or 7 LSBs. The choice of 7 or 4-bit address detection is done using the ADDM7 bit. This 4-bit/7-bit word is compared by the receiver with its own address which is programmed in the ADD bits in the USART\_CR2 register.

**Note:** *In 7-bit and 9-bit data modes, address detection is done on 6-bit and 8-bit addresses (ADD[5:0] and ADD[7:0]) respectively.*

The USART enters mute mode when an address character is received which does not match its programmed address. In this case, the RWU bit is set by hardware. The RXNE flag is not set for this address byte and no interrupt or DMA request is issued when the USART enters mute mode.

The USART also enters mute mode when the MMRQ bit is written to 1. The RWU bit is also automatically set in this case.

The USART exits from mute mode when an address character is received which matches the programmed address. Then the RWU bit is cleared and subsequent bytes are received normally. The RXNE bit is set for the address character since the RWU bit has been cleared.

An example of mute mode behavior using address mark detection is given in [Figure 428](#).

**Figure 428. Mute mode using address mark detection**

## 40.5.8 Modbus communication using USART

The USART offers basic support for the implementation of Modbus/RTU and Modbus/ASCII protocols. Modbus/RTU is a half duplex, block transfer protocol. The control part of the protocol (address recognition, block integrity control and command interpretation) must be implemented in software.

The USART offers basic support for the end of the block detection, without software overhead or other resources.

### Modbus/RTU

In this mode, the end of one block is recognized by a “silence” (idle line) for more than 2 character times. This function is implemented through the programmable timeout function.

The timeout function and interrupt must be activated, through the RTOEN bit in the USART\_CR2 register and the RTOIE in the USART\_CR1 register. The value corresponding to a timeout of 2 character times (for example 22 x bit duration) must be programmed in the RTO register. When the receive line is idle for this duration, after the last stop bit is received, an interrupt is generated, informing the software that the current block reception is completed.

## Modbus/ASCII

In this mode, the end of a block is recognized by a specific (CR/LF) character sequence. The USART manages this mechanism using the character match function.

By programming the LF ASCII code in the ADD[7:0] field and by activating the character match interrupt (CMIE=1), the software is informed when a LF has been received and can check the CR/LF in the DMA buffer.

### 40.5.9 USART parity control

Parity control (generation of parity bit in transmission and parity checking in reception) can be enabled by setting the PCE bit in the USART\_CR1 register. Depending on the frame length defined by the M bits, the possible USART frame formats are as listed in [Table 252](#).

**Table 252. Frame formats**

| M bits | PCE bit | USART frame <sup>(1)</sup> |
|--------|---------|----------------------------|
| 00     | 0       | SB   8-bit data   STB      |
| 00     | 1       | SB   7-bit data   PB   STB |
| 01     | 0       | SB   9-bit data   STB      |
| 01     | 1       | SB   8-bit data   PB   STB |
| 10     | 0       | SB   7-bit data   STB      |
| 10     | 1       | SB   6-bit data   PB   STB |

1. Legends: SB: start bit, STB: stop bit, PB: parity bit. In the data register, the PB is always taking the MSB position (9th, 8th or 7th, depending on the M bits value).

#### Even parity

The parity bit is calculated to obtain an even number of “1s” inside the frame of the 6, 7 or 8 LSB bits (depending on M bits values) and the parity bit.

As an example, if data=00110101, and 4 bits are set, then the parity bit is 0 if even parity is selected (PS bit in USART\_CR1 = 0).

#### Odd parity

The parity bit is calculated to obtain an odd number of “1s” inside the frame made of the 6, 7 or 8 LSB bits (depending on M bits values) and the parity bit.

As an example, if data=00110101 and 4 bits set, then the parity bit is 1 if odd parity is selected (PS bit in USART\_CR1 = 1).

#### Parity checking in reception

If the parity check fails, the PE flag is set in the USART\_ISR register and an interrupt is generated if PEIE is set in the USART\_CR1 register. The PE flag is cleared by software writing 1 to the PECF in the USART\_ICR register.

### Parity generation in transmission

If the PCE bit is set in USART\_CR1, then the MSB bit of the data written in the data register is transmitted but is changed by the parity bit (even number of “1s” if even parity is selected (PS=0) or an odd number of “1s” if odd parity is selected (PS=1)).

## 40.5.10 USART LIN (local interconnection network) mode

This section is relevant only when LIN mode is supported. Please refer to [Section 40.4: USART implementation on page 1323](#).

The LIN mode is selected by setting the LINEN bit in the USART\_CR2 register. In LIN mode, the following bits must be kept cleared:

- STOP[1:0] and CLKEN in the USART\_CR2 register,
- SCEN, HDSEL and IREN in the USART\_CR3 register.

### LIN transmission

The procedure explained in [Section 40.5.2: USART transmitter](#) has to be applied for LIN Master transmission. It must be the same as for normal USART transmission with the following differences:

- Clear the M bits to configure 8-bit word length.
- Set the LINEN bit to enter LIN mode. In this case, setting the SBKRQ bit sends 13 ‘0’ bits as a break character. Then 2 bits of value ‘1’ are sent to allow the next start detection.

### LIN reception

When LIN mode is enabled, the break detection circuit is activated. The detection is totally independent from the normal USART receiver. A break can be detected whenever it occurs, during Idle state or during a frame.

When the receiver is enabled (RE=1 in USART\_CR1), the circuit looks at the RX input for a start signal. The method for detecting start bits is the same when searching break characters or data. After a start bit has been detected, the circuit samples the next bits exactly like for the data (on the 8th, 9th and 10th samples). If 10 (when the LBDL = 0 in USART\_CR2) or 11 (when LBDL=1 in USART\_CR2) consecutive bits are detected as ‘0’, and are followed by a delimiter character, the LBDF flag is set in USART\_ISR. If the LBDIE bit=1, an interrupt is generated. Before validating the break, the delimiter is checked for as it signifies that the RX line has returned to a high level.

If a ‘1’ is sampled before the 10 or 11 have occurred, the break detection circuit cancels the current detection and searches for a start bit again.

If the LIN mode is disabled (LINEN=0), the receiver continues working as normal USART, without taking into account the break detection.

If the LIN mode is enabled (LINEN=1), as soon as a framing error occurs (i.e. stop bit detected at ‘0’, which is the case for any break frame), the receiver stops until the break detection circuit receives either a ‘1’, if the break word was not complete, or a delimiter character if a break has been detected.

The behavior of the break detector state machine and the break flag is shown on the [Figure 429: Break detection in LIN mode \(11-bit break length - LBDL bit is set\) on page 1346](#).

Examples of break frames are given on [Figure 430: Break detection in LIN mode vs. Framing error detection on page 1347](#).

Figure 429. Break detection in LIN mode (11-bit break length - LBDL bit is set)

**Figure 430. Break detection in LIN mode vs. Framing error detection**

#### 40.5.11 USART synchronous mode

The synchronous mode is selected by writing the CLKEN bit in the USART\_CR2 register to 1. In synchronous mode, the following bits must be kept cleared:

- LINEN bit in the USART\_CR2 register,
- SCEN, HDSEL and IREN bits in the USART\_CR3 register.

In this mode, the USART can be used to control bidirectional synchronous serial communications in master mode. The CK pin is the output of the USART transmitter clock. No clock pulses are sent to the CK pin during start bit and stop bit. Depending on the state of the LBCL bit in the USART\_CR2 register, clock pulses are, or are not, generated during the last valid data bit (address mark). The CPOL bit in the USART\_CR2 register is used to select the clock polarity, and the CPHA bit in the USART\_CR2 register is used to select the phase of the external clock (see [Figure 431](#), [Figure 432](#) and [Figure 433](#)).

During the Idle state, preamble and send break, the external CK clock is not activated.

In synchronous mode the USART transmitter works exactly like in asynchronous mode. But as CK is synchronized with TX (according to CPOL and CPHA), the data on TX is synchronous.

In this mode the USART receiver works in a different manner compared to the asynchronous mode. If RE=1, the data is sampled on CK (rising or falling edge, depending on CPOL and CPHA), without any oversampling. A setup and a hold time must be respected (which depends on the baud rate: 1/16 bit duration).

**Note:** The CK pin works in conjunction with the TX pin. Thus, the clock is provided only if the transmitter is enabled ( $TE=1$ ) and data is being transmitted (the data register `USART_TDR` written). This means that it is not possible to receive synchronous data without transmitting data.

The LBCL, CPOL and CPHA bits have to be selected when the USART is disabled ( $UE=0$ ) to ensure that the clock pulses function correctly.

**Figure 431. USART example of synchronous transmission**

**Figure 432. USART data clock timing diagram (M bits = 00)**

Figure 433. USART data clock timing diagram (M bits = 01)

Figure 434. RX data setup/hold time

Note: The function of CK is different in smartcard mode. Refer to [Section 40.5.13: USART smartcard mode](#) for more details.

### 40.5.12 USART single-wire half-duplex communication

Single-wire half-duplex mode is selected by setting the HDSEL bit in the USART\_CR3 register. In this mode, the following bits must be kept cleared:

- LINEN and CLKEN bits in the USART\_CR2 register,
- SCEN and IREN bits in the USART\_CR3 register.

The USART can be configured to follow a single-wire half-duplex protocol where the TX and RX lines are internally connected. The selection between half- and Full-duplex communication is made with a control bit HDSEL in USART\_CR3.

As soon as HDSEL is written to 1:

- The TX and RX lines are internally connected
- The RX pin is no longer used
- The TX pin is always released when no data is transmitted. Thus, it acts as a standard I/O in idle or in reception. It means that the I/O must be configured so that TX is configured as alternate function open-drain with an external pull-up.

Apart from this, the communication protocol is similar to normal USART mode. Any conflicts on the line must be managed by software (by the use of a centralized arbiter, for instance). In particular, the transmission is never blocked by hardware and continues as soon as data is written in the data register while the TE bit is set.

### 40.5.13 USART smartcard mode

This section is relevant only when smartcard mode is supported. Please refer to [Section 40.4: USART implementation on page 1323](#).

Smartcard mode is selected by setting the SCEN bit in the USART\_CR3 register. In smartcard mode, the following bits must be kept cleared:

- LINEN bit in the USART\_CR2 register,
- HDSEL and IREN bits in the USART\_CR3 register.

Moreover, the CLKEN bit may be set in order to provide a clock to the smartcard.

The smartcard interface is designed to support asynchronous protocol for smartcards as defined in the ISO 7816-3 standard. Both T=0 (character mode) and T=1 (block mode) are supported.

The USART should be configured as:

- 8 bits plus parity: where word length is set to 8 bits and PCE=1 in the USART\_CR1 register
- 1.5 stop bits when transmitting and receiving data: where STOP=11 in the USART\_CR2 register. It is also possible to choose 0.5 stop bit for receiving.

In T=0 (character) mode, the parity error is indicated at the end of each character during the guard time period.

[Figure 435](#) shows examples of what can be seen on the data line with and without parity error.

Figure 435. ISO 7816-3 asynchronous protocol

When connected to a smartcard, the TX output of the USART drives a bidirectional line that is also driven by the smartcard. The TX pin must be configured as open drain.

Smartcard mode implements a single wire half duplex communication protocol.

- Transmission of data from the transmit shift register is guaranteed to be delayed by a minimum of 1/2 baud clock. In normal operation a full transmit shift register starts shifting on the next baud clock edge. In smartcard mode this transmission is further delayed by a guaranteed 1/2 baud clock.
- In transmission, if the smartcard detects a parity error, it signals this condition to the USART by driving the line low (NACK). This NACK signal (pulling transmit line low for 1 baud clock) causes a framing error on the transmitter side (configured with 1.5 stop bits). The USART can handle automatic re-sending of data according to the protocol. The number of retries is programmed in the SCARCNT bit field. If the USART continues receiving the NACK after the programmed number of retries, it stops transmitting and signals the error as a framing error. The TXE bit can be set using the TXFRQ bit in the USART\_RQR register.
- Smartcard auto-retry in transmission: a delay of 2.5 baud periods is inserted between the NACK detection by the USART and the start bit of the repeated character. The TC bit is set immediately at the end of reception of the last repeated character (no guard-time). If the software wants to repeat it again, it must insure the minimum 2 baud periods required by the standard.
- If a parity error is detected during reception of a frame programmed with a 1.5 stop bits period, the transmit line is pulled low for a baud clock period after the completion of the receive frame. This is to indicate to the smartcard that the data transmitted to the USART has not been correctly received. A parity error is NACKed by the receiver if the NACK control bit is set, otherwise a NACK is not transmitted (to be used in T=1 mode). If the received character is erroneous, the RXNE/receive DMA request is not activated. According to the protocol specification, the smartcard must resend the same character. If the received character is still erroneous after the maximum number of retries specified in the SCARCNT bit field, the USART stops transmitting the NACK and signals the error as a parity error.
- Smartcard auto-retry in reception: the BUSY flag remains set if the USART NACKs the card but the card doesn't repeat the character.

- In transmission, the USART inserts the Guard Time (as programmed in the Guard Time register) between two successive characters. As the Guard Time is measured after the stop bit of the previous character, the GT[7:0] register must be programmed to the desired CGT (Character Guard Time, as defined by the 7816-3 specification) minus 12 (the duration of one character).
- The assertion of the TC flag can be delayed by programming the Guard Time register. In normal operation, TC is asserted when the transmit shift register is empty and no further transmit requests are outstanding. In smartcard mode an empty transmit shift register triggers the Guard Time counter to count up to the programmed value in the Guard Time register. TC is forced low during this time. When the Guard Time counter reaches the programmed value TC is asserted high.
- The TCBGT flag can be used to detect the end of data transfer without waiting for guard time completion. This flag is set just after the end of frame transmission and if no NACK has been received from the card.
- The de-assertion of TC flag is unaffected by smartcard mode.
- If a framing error is detected on the transmitter end (due to a NACK from the receiver), the NACK is not detected as a start bit by the receive block of the transmitter. According to the ISO protocol, the duration of the received NACK can be 1 or 2 baud clock periods.
- On the receiver side, if a parity error is detected and a NACK is transmitted the receiver does not detect the NACK as a start bit.

**Note:** A break character is not significant in smartcard mode. A 0x00 data with a framing error is treated as data and not as a break.

No Idle frame is transmitted when toggling the TE bit. The Idle frame (as defined for the other configurations) is not defined by the ISO protocol.

Figure 436 details how the NACK signal is sampled by the USART. In this example the USART is transmitting data and is configured with 1.5 stop bits. The receiver part of the USART is enabled in order to check the integrity of the data and the NACK signal.

**Figure 436. Parity error detection using the 1.5 stop bits**

The USART can provide a clock to the smartcard through the CK output. In smartcard mode, CK is not associated to the communication but is simply derived from the internal peripheral input clock through a 5-bit prescaler. The division ratio is configured in the prescaler register USART\_GTPR. CK frequency can be programmed from  $f_{CK}/2$  to  $f_{CK}/62$ , where  $f_{CK}$  is the peripheral input clock.

### Block mode (T=1)

In T=1 (block) mode, the parity error transmission is deactivated, by clearing the NACK bit in the UART\_CR3 register.

When requesting a read from the smartcard, in block mode, the software must enable the receiver Timeout feature by setting the RTOEN bit in the USART\_CR2 register and program the RTO bits field in the RTOR register to the BWT (block wait time) - 11 value. If no answer is received from the card before the expiration of this period, the RTOF flag is set and a timeout interrupt is generated (if RTOIE bit in the USART\_CR1 register is set). If the first character is received before the expiration of the period, it is signaled by the RXNE interrupt.

*Note: The RXNE interrupt must be enabled even when using the USART in DMA mode to read from the smartcard in block mode. In parallel, the DMA must be enabled only after the first received byte.*

After the reception of the first character (RXNE interrupt), the RTO bit fields in the RTOR register must be programmed to the CWT (character wait time) - 11 value, in order to allow the automatic check of the maximum wait time between two consecutive characters. This time is expressed in baudtime units. If the smartcard does not send a new character in less than the CWT period after the end of the previous character, the USART signals this to the software through the RTOF flag and interrupt (when RTOIE bit is set).

*Note: The RTO counter starts counting:*

- From the end of the stop bit in case STOP = 00.
- From the end of the second stop bit in case of STOP = 10.
- 1 bit duration after the beginning of the STOP bit in case STOP = 11.
- From the beginning of the STOP bit in case STOP = 01.

*As in the smartcard protocol definition, the BWT/CWT values are defined from the beginning (start bit) of the last character. The RTO register must be programmed to BWT -11 or CWT - 11, respectively, taking into account the length of the last character itself.*

A block length counter is used to count all the characters received by the USART. This counter is reset when the USART is transmitting (TXE=0). The length of the block is communicated by the smartcard in the third byte of the block (prologue field). This value must be programmed to the BLEN field in the USART\_RTOR register. when using DMA mode, before the start of the block, this register field must be programmed to the minimum value (0x0). with this value, an interrupt is generated after the 4th received character. The software must read the LEN field (third byte), its value must be read from the receive buffer.

In interrupt driven receive mode, the length of the block may be checked by software or by programming the BLEN value. However, before the start of the block, the maximum value of BLEN (0xFF) may be programmed. The real value is programmed after the reception of the third character.

If the block is using the LRC longitudinal redundancy check (1 epilogue byte), the BLEN=LEN. If the block is using the CRC mechanism (2 epilogue bytes), BLEN=LEN+1 must be programmed. The total block length (including prologue, epilogue and information fields) equals BLEN+4. The end of the block is signaled to the software through the EOBFF flag and interrupt (when EOBIE bit is set).

In case of an error in the block length, the end of the block is signaled by the RTO interrupt (Character wait Time overflow).

*Note: The error checking code (LRC/CRC) must be computed/verified by software.*

## Direct and inverse convention

The smartcard protocol defines two conventions: direct and inverse.

The direct convention is defined as: LSB first, logical bit value of 1 corresponds to a H state of the line and parity is even. In order to use this convention, the following control bits must be programmed: MSBFIRST=0, DATAINV=0 (default values).

The inverse convention is defined as: MSB first, logical bit value 1 corresponds to an L state on the signal line and parity is even. In order to use this convention, the following control bits must be programmed: MSBFIRST=1, DATAINV=1.

*Note:* When logical data values are inverted (0=H, 1=L), the parity bit is also inverted in the same way.

In order to recognize the card convention, the card sends the initial character, TS, as the first character of the ATR (Answer To Reset) frame. The two possible patterns for the TS are: LHHL LLL LLH and LHHL HHH LLH.

- (H) LHHL LLL LLH sets up the inverse convention: state L encodes value 1 and moment 2 conveys the most significant bit (MSB first). when decoded by inverse convention, the conveyed byte is equal to '3F'.
- (H) LHHL HHH LLH sets up the direct convention: state H encodes value 1 and moment 2 conveys the least significant bit (LSB first). when decoded by direct convention, the conveyed byte is equal to '3B'.

Character parity is correct when there is an even number of bits set to 1 in the nine moments 2 to 10.

As the USART does not know which convention is used by the card, it needs to be able to recognize either pattern and act accordingly. The pattern recognition is not done in hardware, but through a software sequence. Moreover, supposing that the USART is configured in direct convention (default) and the card answers with the inverse convention, TS = LHHL LLL LLH => the USART received character is '03' and the parity is odd.

Therefore, two methods are available for TS pattern recognition:

### Method 1

The USART is programmed in standard smartcard mode/direct convention. In this case, the TS pattern reception generates a parity error interrupt and error signal to the card.

- The parity error interrupt informs the software that the card didn't answer correctly in direct convention. Software then reprograms the USART for inverse convention
- In response to the error signal, the card retries the same TS character, and it is correctly received this time, by the reprogrammed USART

Alternatively, in answer to the parity error interrupt, the software may decide to reprogram the USART and to also generate a new reset command to the card, then wait again for the TS.

### Method 2

The USART is programmed in 9-bit/no-parity mode, no bit inversion. In this mode it receives any of the two TS patterns as:

(H) LHHL LLL LLH = 0x103 -> inverse convention to be chosen

(H) LHHL HHH LLH = 0x13B -> direct convention to be chosen

The software checks the received character against these two patterns and, if any of them match, then programs the USART accordingly for the next character reception.

If none of the two is recognized, a card reset may be generated in order to restart the negotiation.

#### 40.5.14 USART IrDA SIR ENDEC block

This section is relevant only when IrDA mode is supported. Please refer to [Section 40.4: USART implementation on page 1323](#).

IrDA mode is selected by setting the IREN bit in the USART\_CR3 register. In IrDA mode, the following bits must be kept cleared:

- LINEN, STOP and CLKEN bits in the USART\_CR2 register,
- SCEN and HDSEL bits in the USART\_CR3 register.

The IrDA SIR physical layer specifies use of a Return to Zero, Inverted (RZI) modulation scheme that represents logic 0 as an infrared light pulse (see [Figure 437](#)).

The SIR Transmit encoder modulates the Non Return to Zero (NRZ) transmit bit stream output from USART. The output pulse stream is transmitted to an external output driver and infrared LED. USART supports only bit rates up to 115.2 Kbps for the SIR ENDEC. In normal mode the transmitted pulse width is specified as 3/16 of a bit period.

The SIR receive decoder demodulates the return-to-zero bit stream from the infrared detector and outputs the received NRZ serial bit stream to the USART. The decoder input is normally high (marking state) in the Idle state. The transmit encoder output has the opposite polarity to the decoder input. A start bit is detected when the decoder input is low.

- IrDA is a half duplex communication protocol. If the Transmitter is busy (when the USART is sending data to the IrDA encoder), any data on the IrDA receive line is ignored by the IrDA decoder and if the Receiver is busy (when the USART is receiving decoded data from the IrDA decoder), data on the TX from the USART to IrDA is not encoded. while receiving data, transmission should be avoided as the data to be transmitted could be corrupted.
- A 0 is transmitted as a high pulse and a 1 is transmitted as a 0. The width of the pulse is specified as 3/16th of the selected bit period in normal mode (see [Figure 438](#)).
- The SIR decoder converts the IrDA compliant receive signal into a bit stream for USART.
- The SIR receive logic interprets a high state as a logic one and low pulses as logic zeros.
- The transmit encoder output has the opposite polarity to the decoder input. The SIR output is in low state when Idle.
- The IrDA specification requires the acceptance of pulses greater than 1.41  $\mu$ s. The acceptable pulse width is programmable. Glitch detection logic on the receiver end filters out pulses of width less than 2 PSC periods (PSC is the prescaler value programmed in the USART\_GTPR). Pulses of width less than 1 PSC period are always rejected, but those of width greater than one and less than two periods may be accepted or rejected, those greater than 2 periods is accepted as a pulse. The IrDA encoder/decoder doesn't work when PSC=0.
- The receiver can communicate with a low-power transmitter.
- In IrDA mode, the STOP bits in the USART\_CR2 register must be configured to "1 stop bit".

## IrDA low-power mode

### Transmitter

In low-power mode the pulse width is not maintained at 3/16 of the bit period. Instead, the width of the pulse is 3 times the low-power baud rate which can be a minimum of 1.42 MHz.

Generally, this value is 1.8432 MHz ( $1.42 \text{ MHz} < \text{PSC} < 2.12 \text{ MHz}$ ). A low-power mode programmable divisor divides the system clock to achieve this value.

### Receiver

Receiving in low-power mode is similar to receiving in normal mode. For glitch detection the USART should discard pulses of duration shorter than 1 PSC period. A valid low is accepted only if its duration is greater than 2 periods of the IrDA low-power Baud clock (PSC value in the USART\_GTPR).

**Note:** A pulse of width less than two and greater than one PSC period(s) may or may not be rejected.

The receiver set up time should be managed by software. The IrDA physical layer specification specifies a minimum of 10 ms delay between transmission and reception (IrDA is a half duplex protocol).

Figure 438. IrDA data modulation (3/16) - normal mode

### 40.5.15 USART continuous communication in DMA mode

The USART is capable of performing continuous communication using the DMA. The DMA requests for Rx buffer and Tx buffer are generated independently.

*Note:* Please refer to [Section 40.4: USART implementation on page 1323](#) to determine if the DMA mode is supported. If DMA is not supported, use the USART as explained in [Section 40.5.2: USART transmitter](#) or [Section 40.5.3: USART receiver](#). To perform continuous communication, the user can clear the TXE/ RXNE flags in the USART\_ISR register.

#### Transmission using DMA

DMA mode can be enabled for transmission by setting DMAT bit in the USART\_CR3 register. Data is loaded from a SRAM area configured using the DMA peripheral (refer to [Section 11: Direct memory access controller \(DMA\) on page 336](#)) to the USART\_TDR register whenever the TXE bit is set. To map a DMA channel for USART transmission, use the following procedure (x denotes the channel number):

1. Write the USART\_TDR register address in the DMA control register to configure it as the destination of the transfer. The data is moved to this address from memory after each TXE event.
2. Write the memory address in the DMA control register to configure it as the source of the transfer. The data is loaded into the USART\_TDR register from this memory area after each TXE event.
3. Configure the total number of bytes to be transferred to the DMA control register.
4. Configure the channel priority in the DMA register
5. Configure DMA interrupt generation after half/ full transfer as required by the application.
6. Clear the TC flag in the USART\_ISR register by setting the TCCF bit in the USART\_ICR register.
7. Activate the channel in the DMA register.

When the number of data transfers programmed in the DMA Controller is reached, the DMA controller generates an interrupt on the DMA channel interrupt vector.

In transmission mode, once the DMA has written all the data to be transmitted (the TCIF flag is set in the DMA\_ISR register), the TC flag can be monitored to make sure that the USART communication is complete. This is required to avoid corrupting the last transmission before disabling the USART or entering Stop mode. Software must wait until TC=1. The TC flag remains cleared during all data transfers and it is set by hardware at the end of transmission of the last frame.

Figure 439. Transmission using DMA

### Reception using DMA

DMA mode can be enabled for reception by setting the DMAR bit in USART\_CR3 register. Data is loaded from the USART\_RDR register to a SRAM area configured using the DMA peripheral (refer to [Section 11: Direct memory access controller \(DMA\) on page 336](#)) whenever a data byte is received. To map a DMA channel for USART reception, use the following procedure:

1. Write the USART\_RDR register address in the DMA control register to configure it as the source of the transfer. The data is moved from this address to the memory after each RXNE event.
2. Write the memory address in the DMA control register to configure it as the destination of the transfer. The data is loaded from USART\_RDR to this memory area after each RXNE event.
3. Configure the total number of bytes to be transferred to the DMA control register.
4. Configure the channel priority in the DMA control register.
5. Configure interrupt generation after half/ full transfer as required by the application.
6. Activate the channel in the DMA control register.

When the number of data transfers programmed in the DMA Controller is reached, the DMA controller generates an interrupt on the DMA channel interrupt vector.

Figure 440. Reception using DMA

### Error flagging and interrupt generation in multibuffer communication

In multibuffer communication if any error occurs during the transaction the error flag is asserted after the current byte. An interrupt is generated if the interrupt enable flag is set. For framing error, overrun error and noise flag which are asserted with RXNE in single byte reception, there is a separate error flag interrupt enable bit (EIE bit in the USART\_CR3 register), which, if set, enables an interrupt after the current byte if any of these errors occur.

#### 40.5.16 RS232 hardware flow control and RS485 driver enable using USART

It is possible to control the serial data flow between 2 devices by using the CTS input and the RTS output. The [Figure 441](#) shows how to connect 2 devices in this mode:

Figure 441. Hardware flow control between 2 USARTs

RS232 RTS and CTS flow control can be enabled independently by writing the RTSE and CTSE bits respectively to 1 (in the USART\_CR3 register).

### RS232 RTS flow control

If the RTS flow control is enabled (RTSE=1), then RTS is deasserted (tied low) as long as the USART receiver is ready to receive a new data. When the receive register is full, RTS is asserted, indicating that the transmission is expected to stop at the end of the current frame. [Figure 442](#) shows an example of communication with RTS flow control enabled.

**Figure 442. RS232 RTS flow control**

### RS232 CTS flow control

If the CTS flow control is enabled (CTSE=1), then the transmitter checks the CTS input before transmitting the next frame. If CTS is deasserted (tied low), then the next data is transmitted (assuming that data is to be transmitted, in other words, if TXE=0), else the transmission does not occur. When CTS is asserted during a transmission, the current transmission is completed before the transmitter stops.

When CTSE=1, the CTSIF status bit is automatically set by hardware as soon as the CTS input toggles. It indicates when the receiver becomes ready or not ready for communication. An interrupt is generated if the CTSIE bit in the USART\_CR3 register is set. [Figure 443](#) shows an example of communication with CTS flow control enabled.

Figure 443. RS232 CTS flow control

**Note:** For correct behavior, CTS must be deasserted at least 3 USART clock source periods before the end of the current character. In addition it should be noted that the CTSCF flag may not be set for pulses shorter than  $2 \times PCLK$  periods.

### RS485 Driver Enable

The driver enable feature is enabled by setting bit DEM in the USART\_CR3 control register. This allows the user to activate the external transceiver control, through the DE (Driver Enable) signal. The assertion time is the time between the activation of the DE signal and the beginning of the START bit. It is programmed using the DEAT [4:0] bit fields in the USART\_CR1 control register. The de-assertion time is the time between the end of the last stop bit, in a transmitted message, and the de-activation of the DE signal. It is programmed using the DEDT [4:0] bit fields in the USART\_CR1 control register. The polarity of the DE signal can be configured using the DEP bit in the USART\_CR3 control register.

In USART, the DEAT and DEDT are expressed in sample time units ( $1/8$  or  $1/16$  bit duration, depending on the oversampling rate).

## 40.5.17 Wake-up from Stop mode using USART

The USART is able to wake up the MCU from Stop mode when the UESM bit is set and the USART clock is set to HSI16 or LSE (refer to Section Reset and clock control (RCC)).

- USART source clock is HSI

If during Stop mode the HSI clock is switched OFF, when a falling edge on the USART receive line is detected, the USART interface requests the HSI clock to be switched ON. The HSI clock is then used for the frame reception.

- If the wake-up event is verified, the MCU wakes up from low-power mode and data reception goes on normally.
- If the wake-up event is not verified, the HSI clock is switched OFF again, the MCU is not waken up and stays in low-power mode and the clock request is released.

**Note:** *If the USART kernel clock is kept ON during Stop mode, there is no constraint on the maximum baud rate that allows waking up from Stop mode. It is the same as in Run mode.*

- USART source clock is LSE

Same principle as described in case of USART source clock is HSI with the difference that the LSE is ON in Stop mode, but the LSE clock is not propagated to USART if the USART is not requesting it. The LSE clock is not OFF but there is a clock gating to avoid useless consumption.

When the USART clock source is configured to be  $f_{LSE}$  or  $f_{HSI}$ , it is possible to keep enabled this clock during Stop mode by setting the UCESM bit in USART\_CR3 control register.

The MCU wake-up from Stop mode can be done using the standard RXNE interrupt. In this case, the RXNEIE bit must be set before entering Stop mode.

Alternatively, a specific interrupt may be selected through the WUS bit fields.

In order to be able to wake up the MCU from Stop mode, the UESM bit in the USART\_CR1 control register must be set prior to entering Stop mode.

When the wake-up event is detected, the WUF flag is set by hardware and a wake-up interrupt is generated if the WUFIE bit is set.

**Note:** *Before entering Stop mode, the user must ensure that the USART is not performing a transfer. BUSY flag cannot ensure that Stop mode is never entered during a running reception.*

*The WUF flag is set when a wake-up event is detected, independently of whether the MCU is in Stop or in an active mode.*

*When entering Stop mode just after having initialized and enabled the receiver, the REACK bit must be checked to ensure the USART is actually enabled.*

*When DMA is used for reception, it must be disabled before entering Stop mode and re-enabled upon exit from Stop mode.*

*The wake-up from Stop mode feature is not available for all modes. For example it doesn't work in SPI mode because the SPI operates in master mode only.*

### Using mute mode with Stop mode

If the USART is put into mute mode before entering Stop mode:

- Wake-up from mute mode on idle detection must not be used, because idle detection cannot work in Stop mode.
- If the wake-up from mute mode on address match is used, then the source of wake-up from Stop mode must also be the address match. If the RXNE flag is set when entering the Stop mode, the interface will remain in mute mode upon address match and wake up from Stop.
- If the USART is configured to wake up the MCU from Stop mode on START bit detection, the WUF flag is set, but the RXNE flag is not set.

### Determining the maximum USART baud rate allowing to wake up correctly from Stop mode when the USART clock source is the HSI clock

The maximum baud rate allowing to wake up correctly from Stop mode depends on:

- the parameter  $t_{WUUSART}$  provided in the device datasheet
- the USART receiver tolerance provided in the [Section 40.5.5: Tolerance of the USART receiver to clock deviation](#).

Let us take this example: OVER8 = 0, M bits = 10, ONEBIT = 1, BRR [3:0] = 0000.

In these conditions, according to [Table 250: Tolerance of the USART receiver when BRR \[3:0\] = 0000](#), the USART receiver tolerance is 4.86 %.

$DTRA + DQUANT + DREC + DTCL + DWU < \text{USART receiver's tolerance}$

$DWU_{\text{max}} = t_{WU\text{USART}} / (9 \times \text{Tbit Min})$

$\text{Tbit Min} = t_{WU\text{USART}} / (9 \times DWU_{\text{max}})$

If we consider an ideal case where the parameters DTRA, DQUANT, DREC and DTCL are at 0%, the DWU max is 4.86 %. In reality, we need to consider at least the HSI inaccuracy.

Let us consider the HSI inaccuracy = 1 %,  $t_{WU\text{USART}} = 1.7 \mu\text{s}$  (in case of wake-up from Stop mode 0).

$DWU_{\text{max}} = 4.86 \% - 1 \% = 3.86 \%$

$\text{Tbit min} = 1.7 \mu\text{s} / (9 \times 3.86 \%) = 4.89 \mu\text{s}$

In these conditions, the maximum baud rate allowing to wake up correctly from Stop mode is  $1/4.89 \mu\text{s} = 204 \text{ kbaud}$ .

## 40.6 USART in low-power modes

**Table 253. Effect of low-power modes on the USART**

| Mode            | Description                                                                                                                                                                                                                                                                              |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Sleep           | No effect. USART interrupt causes the device to exit Sleep mode.                                                                                                                                                                                                                         |
| Low-power run   | No effect.                                                                                                                                                                                                                                                                               |
| Low-power sleep | No effect. USART interrupt causes the device to exit Low-power sleep mode.                                                                                                                                                                                                               |
| Stop 0 / Stop 1 | The USART registers content is kept. The USART is able to wake up the MCU from Stop 0 and Stop 1 modes when the UESM bit is set and the USART clock is set to HSI16 or LSE.<br>The MCU wake-up from Stop 0 and Stop 1 modes can be done using either a standard RXNE or a WUF interrupt. |
| Stop 2          | The USART registers content is kept. The USART must either be disabled or put in reset state.                                                                                                                                                                                            |
| Standby         | The USART is powered down and must be reinitialized when the device has exited from Standby or Shutdown mode.                                                                                                                                                                            |
| Shutdown        |                                                                                                                                                                                                                                                                                          |

## 40.7 USART interrupts

**Table 254. USART interrupt requests**

| Interrupt event              | Event flag | Enable Control bit |
|------------------------------|------------|--------------------|
| Transmit data register empty | TXE        | TXEIE              |
| CTS interrupt                | CTSIF      | CTSIE              |

Table 254. USART interrupt requests (continued)

| Interrupt event                                                           | Event flag         | Enable Control bit |
|---------------------------------------------------------------------------|--------------------|--------------------|
| Transmission Complete                                                     | TC                 | TCIE               |
| Receive data register not empty (data ready to be read)                   | RXNE               | RXNEIE             |
| Overrun error detected                                                    | ORE                |                    |
| Idle line detected                                                        | IDLE               | IDLEIE             |
| Parity error                                                              | PE                 | PEIE               |
| LIN break                                                                 | LBDF               | LBDIE              |
| Noise Flag, Overrun error and Framing Error in multibuffer communication. | NF or ORE or FE    | EIE                |
| Character match                                                           | CMF                | CMIE               |
| Receiver timeout                                                          | RTOF               | RTOIE              |
| End of Block                                                              | EOBF               | EOBIE              |
| Wake-up from Stop mode                                                    | WUF <sup>(1)</sup> | WUFIE              |
| Transmission complete before guard time <sup>(2)</sup>                    | TCBGT              | TCBGTIE            |

1. The WUF interrupt is active only in Stop mode.

2. Available on STM32L49x/L4Ax devices only.

The USART interrupt events are connected to the same interrupt vector (see [Figure 444](#)).

- During transmission: Transmission Complete, Transmission complete before guard time, Clear to Send, Transmit data Register empty or Framing error (in smartcard mode) interrupt.
- During reception: Idle Line detection, Overrun error, Receive data register not empty, Parity error, LIN break detection, Noise Flag, Framing Error, Character match, etc.

These events generate an interrupt if the corresponding Enable Control Bit is set.

Figure 444. USART interrupt mapping diagram

## 40.8 USART registers

Refer to [Section 1.2 on page 69](#) for a list of abbreviations used in register descriptions.

The peripheral registers have to be accessed by words (32 bits).

### 40.8.1 USART control register 1 (USART\_CR1)

Address offset: 0x00

Reset value: 0x0000 0000

| 31    | 30   | 29   | 28 | 27    | 26    | 25        | 24   | 23    | 22   | 21     | 20        | 19 | 18 | 17   | 16 |
|-------|------|------|----|-------|-------|-----------|------|-------|------|--------|-----------|----|----|------|----|
| Res.  | Res. | Res. | M1 | EOBIE | RTOIE | DEAT[4:0] |      |       |      |        | DEDT[4:0] |    |    |      |    |
|       |      |      | rw | rw    | rw    | rw        | rw   | rw    | rw   | rw     | rw        | rw | rw | rw   | rw |
| 15    | 14   | 13   | 12 | 11    | 10    | 9         | 8    | 7     | 6    | 5      | 4         | 3  | 2  | 1    | 0  |
| OVER8 | CMIE | MME  | M0 | WAKE  | PCE   | PS        | PEIE | TXEIE | TCIE | RXNEIE | IDLEIE    | TE | RE | UESM | UE |
| rw    | rw   | rw   | rw | rw    | rw    | rw        | rw   | rw    | rw   | rw     | rw        | rw | rw | rw   | rw |

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **M1**: Word length

This bit, with bit 12 (M0), determines the word length. It is set or cleared by software.

M[1:0] = 00: 1 Start bit, 8 data bits, n stop bits

M[1:0] = 01: 1 Start bit, 9 data bits, n stop bits

M[1:0] = 10: 1 Start bit, 7 data bits, n stop bits

This bit can only be written when the USART is disabled (UE=0).

*Note: Not all modes are supported in 7-bit data length mode. Refer to [Section 40.4: USART implementation](#) for details.*

Bit 27 **EOBIE**: End of Block interrupt enable

This bit is set and cleared by software.

0: Interrupt is inhibited

1: A USART interrupt is generated when the EOBF flag is set in the USART\_ISR register.

*Note: If the USART does not support smartcard mode, this bit is reserved and must be kept at reset value. Please refer to [Section 40.4: USART implementation on page 1323](#).*

Bit 26 **RTOIE**: Receiver timeout interrupt enable

This bit is set and cleared by software.

0: Interrupt is inhibited

1: An USART interrupt is generated when the RTOF bit is set in the USART\_ISR register.

*Note: If the USART does not support the Receiver timeout feature, this bit is reserved and must be kept at reset value. [Section 40.4: USART implementation on page 1323](#).*

Bits 25:21 **DEAT[4:0]**: Driver Enable assertion time

This 5-bit value defines the time between the activation of the DE (Driver Enable) signal and the beginning of the start bit. It is expressed in sample time units (1/8 or 1/16 bit duration, depending on the oversampling rate).

This bit field can only be written when the USART is disabled (UE=0).

*Note: If the Driver Enable feature is not supported, this bit is reserved and must be kept at reset value. Please refer to [Section 40.4: USART implementation on page 1323](#).*

Bits 20:16 **DEDT[4:0]**: Driver Enable de-assertion time

This 5-bit value defines the time between the end of the last stop bit, in a transmitted message, and the de-activation of the DE (Driver Enable) signal. It is expressed in sample time units (1/8 or 1/16 bit duration, depending on the oversampling rate).

If the USART\_TDR register is written during the DEDT time, the new data is transmitted only when the DEDT and DEAT times have both elapsed.

This bit field can only be written when the USART is disabled (UE=0).

*Note: If the Driver Enable feature is not supported, this bit is reserved and must be kept at reset value. Please refer to [Section 40.4: USART implementation on page 1323](#).*

Bit 15 **OVER8**: Oversampling mode

0: Oversampling by 16

1: Oversampling by 8

This bit can only be written when the USART is disabled (UE=0).

*Note: In LIN, IrDA and modes, this bit must be kept at reset value.*

Bit 14 **CMIE**: Character match interrupt enable

This bit is set and cleared by software.

0: Interrupt is inhibited

1: A USART interrupt is generated when the CMF bit is set in the USART\_ISR register.

Bit 13 **MME**: Mute mode enable

This bit activates the mute mode function of the USART. when set, the USART can switch between the active and mute modes, as defined by the WAKE bit. It is set and cleared by software.

0: Receiver in active mode permanently

1: Receiver can switch between mute mode and active mode.

Bit 12 **M0**: Word length

This bit, with bit 28 (M1), determines the word length. It is set or cleared by software. See Bit 28 (M1) description.

This bit can only be written when the USART is disabled (UE=0).

Bit 11 **WAKE**: Receiver wake-up method

This bit determines the USART wake-up method from mute mode. It is set or cleared by software.

0: Idle line

1: Address mark

This bit field can only be written when the USART is disabled (UE=0).

Bit 10 **PCE**: Parity control enable

This bit selects the hardware parity control (generation and detection). When the parity control is enabled, the computed parity is inserted at the MSB position (9th bit if M=1; 8th bit if M=0) and parity is checked on the received data. This bit is set and cleared by software.

Once it is set, PCE is active after the current byte (in reception and in transmission).

0: Parity control disabled

1: Parity control enabled

This bit field can only be written when the USART is disabled (UE=0).

Bit 9 **PS**: Parity selection

This bit selects the odd or even parity when the parity generation/detection is enabled (PCE bit set). It is set and cleared by software. The parity is selected after the current byte.

0: Even parity

1: Odd parity

This bit field can only be written when the USART is disabled (UE=0).

Bit 8 **PEIE**: PE interrupt enable

This bit is set and cleared by software.

0: Interrupt is inhibited

1: A USART interrupt is generated whenever PE=1 in the USART\_ISR register

Bit 7 **TXEIE**: interrupt enable

This bit is set and cleared by software.

0: Interrupt is inhibited

1: A USART interrupt is generated whenever TXE=1 in the USART\_ISR register

Bit 6 **TCIE**: Transmission complete interrupt enable

This bit is set and cleared by software.

0: Interrupt is inhibited

1: A USART interrupt is generated whenever TC=1 in the USART\_ISR register

Bit 5 **RXNEIE**: RXNE interrupt enable

This bit is set and cleared by software.

0: Interrupt is inhibited

1: A USART interrupt is generated whenever ORE=1 or RXNE=1 in the USART\_ISR register

Bit 4 **IDLEIE**: IDLE interrupt enable

This bit is set and cleared by software.

0: Interrupt is inhibited

1: A USART interrupt is generated whenever IDLE=1 in the USART\_ISR register

Bit 3 **TE**: Transmitter enable

This bit enables the transmitter. It is set and cleared by software.

0: Transmitter is disabled

1: Transmitter is enabled

*Note: During transmission, a “0” pulse on the TE bit (“0” followed by “1”) sends a preamble (idle line) after the current word, except in smartcard mode. In order to generate an idle character, the TE must not be immediately written to 1. In order to ensure the required duration, the software can poll the TEACK bit in the USART\_ISR register.*  
*In smartcard mode, when TE is set there is a 1 bit-time delay before the transmission starts.*

Bit 2 **RE**: Receiver enable

This bit enables the receiver. It is set and cleared by software.

0: Receiver is disabled

1: Receiver is enabled and begins searching for a start bit

Bit 1 **UESM**: USART enable in Stop mode

When this bit is cleared, the USART is not able to wake up the MCU from Stop mode.

When this bit is set, the USART is able to wake up the MCU from Stop mode, provided that the USART clock selection is HSI16 or LSE in the RCC.

This bit is set and cleared by software.

0: USART not able to wake up the MCU from Stop mode.

1: USART able to wake up the MCU from Stop mode. When this function is active, the clock source for the USART must be HSI16 or LSE (see Section Reset and clock control (RCC)).

*Note: It is recommended to set the UESM bit just before entering Stop mode and clear it on exit from Stop mode.*

*If the USART does not support the wake-up from Stop feature, this bit is reserved and must be kept at reset value. Refer to [Section 40.4: USART implementation on page 1323](#).*

Bit 0 **UE**: USART enable

When this bit is cleared, the USART prescalers and outputs are stopped immediately, and current operations are discarded. The configuration of the USART is kept, but all the status flags, in the USART\_ISR are set to their default values. This bit is set and cleared by software.

0: USART prescaler and outputs disabled, low-power mode

1: USART enabled

*Note: In order to go into low-power mode without generating errors on the line, the TE bit must be reset before and the software must wait for the TC bit in the USART\_ISR to be set before resetting the UE bit.*

*The DMA requests are also reset when UE = 0 so the DMA channel must be disabled before resetting the UE bit.*

## 40.8.2 USART control register 2 (USART\_CR2)

Address offset: 0x04

Reset value: 0x0000 0000

| 31       | 30    | 29        | 28 | 27       | 26   | 25   | 24   | 23    | 22          | 21   | 20    | 19       | 18      | 17    | 16    |
|----------|-------|-----------|----|----------|------|------|------|-------|-------------|------|-------|----------|---------|-------|-------|
| ADD[7:4] |       |           |    | ADD[3:0] |      |      |      | RTOEN | ABRMOD[1:0] |      | ABREN | MSBFIRST | DATAINV | TXINV | RXINV |
| rw       | rw    | rw        | rw | rw       | rw   | rw   | rw   | rw    | rw          | rw   | rw    | rw       | rw      | rw    | rw    |
| 15       | 14    | 13        | 12 | 11       | 10   | 9    | 8    | 7     | 6           | 5    | 4     | 3        | 2       | 1     | 0     |
| SWAP     | LINEN | STOP[1:0] |    | CLKEN    | CPOL | CPHA | LBCL | Res.  | LBDIE       | LBDL | ADDM7 | Res.     | Res.    | Res.  | Res.  |
| rw       | rw    | rw        | rw | rw       | rw   | rw   | rw   |       | rw          | rw   | rw    |          |         |       |       |

**Bits 31:28 ADD[7:4]:** Address of the USART node

This bit-field gives the address of the USART node or a character code to be recognized.

This is used in multiprocessor communication during mute mode or Stop mode, for wake-up with 7-bit address mark detection. The MSB of the character sent by the transmitter should be equal to 1. It may also be used for character detection during normal reception, mute mode inactive (for example, end of block detection in ModBus protocol). In this case, the whole received character (8-bit) is compared to the ADD[7:0] value and CMF flag is set on match.

This bit field can only be written when reception is disabled (RE = 0) or the USART is disabled (UE=0)

**Bits 27:24 ADD[3:0]:** Address of the USART node

This bit-field gives the address of the USART node or a character code to be recognized.

This is used in multiprocessor communication during mute mode or Stop mode, for wake-up with address mark detection.

This bit field can only be written when reception is disabled (RE = 0) or the USART is disabled (UE=0)

**Bit 23 RTOEN:** Receiver timeout enable

This bit is set and cleared by software.

0: Receiver timeout feature disabled.

1: Receiver timeout feature enabled.

When this feature is enabled, the RTOF flag in the USART\_ISR register is set if the RX line is idle (no reception) for the duration programmed in the RTOR (receiver timeout register).

*Note: If the USART does not support the Receiver timeout feature, this bit is reserved and must be kept at reset value. Please refer to [Section 40.4: USART implementation on page 1323](#).*

**Bits 22:21 ABRMOD[1:0]:** Auto baud rate mode

These bits are set and cleared by software.

00: Measurement of the start bit is used to detect the baud rate.

01: Falling edge to falling edge measurement. (the received frame must start with a single bit = 1 -> Frame = Start10xxxxxx)

10: 0x7F frame detection.

11: 0x55 frame detection

This bit field can only be written when ABREN = 0 or the USART is disabled (UE=0).

*Note: If DATAINV=1 and/or MSBFIRST=1 the patterns must be the same on the line, for example 0xAA for MSBFIRST)*

*If the USART does not support the auto baud rate feature, this bit is reserved and must be kept at reset value. Please refer to [Section 40.4: USART implementation on page 1323](#).*

**Bit 20 ABREN:** Auto baud rate enable

This bit is set and cleared by software.

0: Auto baud rate detection is disabled.

1: Auto baud rate detection is enabled.

*Note: If the USART does not support the auto baud rate feature, this bit is reserved and must be kept at reset value. Please refer to [Section 40.4: USART implementation on page 1323](#).*

**Bit 19 MSBFIRST:** Most significant bit first

This bit is set and cleared by software.

0: data is transmitted/received with data bit 0 first, following the start bit.

1: data is transmitted/received with the MSB (bit 7/8/9) first, following the start bit.

This bit field can only be written when the USART is disabled (UE=0).

**Bit 18 DATAINV:** Binary data inversion

This bit is set and cleared by software.

0: Logical data from the data register are send/received in positive/direct logic. (1=H, 0=L)

1: Logical data from the data register are send/received in negative/inverse logic. (1=L, 0=H). The parity bit is also inverted.

This bit field can only be written when the USART is disabled (UE=0).

**Bit 17 TXINV:** TX pin active level inversion

This bit is set and cleared by software.

0: TX pin signal works using the standard logic levels ( $V_{DD}$  =1/idle, Gnd=0/mark)

1: TX pin signal values are inverted. ( $V_{DD}$  =0/mark, Gnd=1/idle).

This allows the use of an external inverter on the TX line.

This bit field can only be written when the USART is disabled (UE=0).

**Bit 16 RXINV:** RX pin active level inversion

This bit is set and cleared by software.

0: RX pin signal works using the standard logic levels ( $V_{DD}$  =1/idle, Gnd=0/mark)

1: RX pin signal values are inverted. ( $V_{DD}$  =0/mark, Gnd=1/idle).

This allows the use of an external inverter on the RX line.

This bit field can only be written when the USART is disabled (UE=0).

**Bit 15 SWAP:** Swap TX/RX pins

This bit is set and cleared by software.

0: TX/RX pins are used as defined in standard pinout

1: The TX and RX pins functions are swapped. This allows to work in the case of a cross-wired connection to another USART.

This bit field can only be written when the USART is disabled (UE=0).

**Bit 14 LINEN:** LIN mode enable

This bit is set and cleared by software.

0: LIN mode disabled

1: LIN mode enabled

The LIN mode enables the capability to send LIN synchronous breaks (13 low bits) using the SBKRQ bit in the USART\_RQR register, and to detect LIN Sync breaks.

This bit field can only be written when the USART is disabled (UE=0).

*Note: If the USART does not support LIN mode, this bit is reserved and must be kept at reset value.*

*Please refer to [Section 40.4: USART implementation on page 1323](#).*

**Bits 13:12 STOP[1:0]:** STOP bits

These bits are used for programming the stop bits.

00: 1 stop bit

01: 0.5 stop bit

10: 2 stop bits

11: 1.5 stop bits

This bit field can only be written when the USART is disabled (UE=0).

**Bit 11 CLKEN:** Clock enable

This bit allows the user to enable the CK pin.

0: CK pin disabled

1: CK pin enabled

This bit can only be written when the USART is disabled (UE=0).

*Note: If neither synchronous mode nor smartcard mode is supported, this bit is reserved and must be kept at reset value. Please refer to [Section 40.4: USART implementation on page 1323](#).*

*In order to provide correctly the CK clock to the smartcard when CK is always available When CLKEN = 1, regardless of the UE bit value, the steps below must be respected:*

- UE = 0

- SCEN = 1

- GTPR configuration (If PSC needs to be configured, it is recommended to configure PSC and GT in a single access to USART\_ GTPR register).

- CLKEN= 1

- UE = 1

**Bit 10 CPOL:** Clock polarity

This bit allows the user to select the polarity of the clock output on the CK pin in synchronous mode.

It works in conjunction with the CPHA bit to produce the desired clock/data relationship

0: Steady low value on CK pin outside transmission window

1: Steady high value on CK pin outside transmission window

This bit can only be written when the USART is disabled (UE=0).

*Note: If synchronous mode is not supported, this bit is reserved and must be kept at reset value.*

*Please refer to [Section 40.4: USART implementation on page 1323](#).*

**Bit 9 CPHA:** Clock phase

This bit is used to select the phase of the clock output on the CK pin in synchronous mode. It works in conjunction with the CPOL bit to produce the desired clock/data relationship (see [Figure 432](#) and [Figure 433](#))

0: The first clock transition is the first data capture edge

1: The second clock transition is the first data capture edge

This bit can only be written when the USART is disabled (UE=0).

*Note: If synchronous mode is not supported, this bit is reserved and must be kept at reset value.*

*Please refer to [Section 40.4: USART implementation on page 1323](#).*

**Bit 8 LBCL:** Last bit clock pulse

This bit is used to select whether the clock pulse associated with the last data bit transmitted (MSB) has to be output on the CK pin in synchronous mode.

0: The clock pulse of the last data bit is not output to the CK pin

1: The clock pulse of the last data bit is output to the CK pin

**Caution:** The last bit is the 7th or 8th or 9th data bit transmitted depending on the 7 or 8 or 9 bit format selected by the M bits in the USART\_CR1 register.

This bit can only be written when the USART is disabled (UE=0).

*Note: If synchronous mode is not supported, this bit is reserved and must be kept at reset value.*

*Please refer to [Section 40.4: USART implementation on page 1323](#).*

**Bit 7** Reserved, must be kept at reset value.

**Bit 6 LBDIE:** LIN break detection interrupt enable

Break interrupt mask (break detection using break delimiter).

0: Interrupt is inhibited

1: An interrupt is generated whenever LBDF=1 in the USART\_ISR register

*Note: If LIN mode is not supported, this bit is reserved and must be kept at reset value. Please refer to [Section 40.4: USART implementation on page 1323](#).*

Bit 5 **LBDL**: LIN break detection length

This bit is for selection between 11 bit or 10 bit break detection.

0: 10-bit break detection

1: 11-bit break detection

This bit can only be written when the USART is disabled (UE=0).

*Note: If LIN mode is not supported, this bit is reserved and must be kept at reset value. Please refer to [Section 40.4: USART implementation on page 1323](#).*

Bit 4 **ADDM7**: 7-bit Address Detection/4-bit Address Detection

This bit is for selection between 4-bit address detection or 7-bit address detection.

0: 4-bit address detection

1: 7-bit address detection (in 8-bit data mode)

This bit can only be written when the USART is disabled (UE=0)

*Note: In 7-bit and 9-bit data modes, the address detection is done on 6-bit and 8-bit address (ADD[5:0] and ADD[7:0]) respectively.*

Bits 3:0 Reserved, must be kept at reset value.

*Note: The 3 bits (CPOL, CPHA, LBCL) should not be written while the transmitter is enabled.*

### 40.8.3 USART control register 3 (USART\_CR3)

Address offset: 0x08

Reset value: 0x0000 0000

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **TCBGTIE**: Transmission complete before guard time interrupt enable

This bit is set and cleared by software.

0: Interrupt is inhibited

1: An USART interrupt is generated whenever TCBGT=1 in the USART\_ISR register.

*Note: If smartcard mode is not supported, this bit is reserved and must be kept at reset value (see [Section 40.4: USART implementation](#)).*

*Note: This bit is available on STM32L49x/L4Ax devices only.*

Bit 23 **UCESM**: USART Clock Enable in Stop mode.

This bit is set and cleared by software.

0: USART Clock is disabled in Stop mode.

1: USART Clock is enabled in Stop mode.

Bit 22 **WUFIE**: Wake-up from Stop mode interrupt enable

This bit is set and cleared by software.

0: Interrupt is inhibited

1: An USART interrupt is generated whenever WUF=1 in the USART\_ISR register

*Note: WUFIE must be set before entering in Stop mode.*

*The WUF interrupt is active only in Stop mode.*

*If the USART does not support the wake-up from Stop feature, this bit is reserved and must be kept at reset value.*

Bits 21:20 **WUS[1:0]**: Wake-up from Stop mode interrupt flag selection

This bit-field specify the event which activates the WUF (wake-up from Stop mode flag).

00: WUF active on address match (as defined by ADD[7:0] and ADDM7)

01: Reserved.

10: WuF active on Start bit detection

11: WUF active on RXNE.

This bit field can only be written when the USART is disabled (UE=0).

*Note: If the USART does not support the wake-up from Stop feature, this bit is reserved and must be kept at reset value.*

Bits 19:17 **SCARCNT[2:0]**: Smartcard auto-retry count

This bit-field specifies the number of retries in transmit and receive, in smartcard mode.

In transmission mode, it specifies the number of automatic retransmission retries, before generating a transmission error (FE bit set).

In reception mode, it specifies the number of erroneous reception trials, before generating a reception error (RXNE and PE bits set).

This bit field must be programmed only when the USART is disabled (UE=0).

When the USART is enabled (UE=1), this bit field may only be written to 0x0, in order to stop retransmission.

0x0: retransmission disabled - No automatic retransmission in transmit mode.

0x1 to 0x7: number of automatic retransmission attempts (before signaling error)

*Note: If smartcard mode is not supported, this bit is reserved and must be kept at reset value. Please refer to [Section 40.4: USART implementation on page 1323](#).*

Bit 16 Reserved, must be kept at reset value.

Bit 15 **DEP**: Driver enable polarity selection

0: DE signal is active high.

1: DE signal is active low.

This bit can only be written when the USART is disabled (UE=0).

*Note: If the Driver Enable feature is not supported, this bit is reserved and must be kept at reset value. Please refer to [Section 40.4: USART implementation on page 1323](#).*

Bit 14 **DEM**: Driver enable mode

This bit allows the user to activate the external transceiver control, through the DE signal.

0: DE function is disabled.

1: DE function is enabled. The DE signal is output on the RTS pin.

This bit can only be written when the USART is disabled (UE=0).

*Note: If the Driver Enable feature is not supported, this bit is reserved and must be kept at reset value. [Section 40.4: USART implementation on page 1323](#).*

**Bit 13 DDRE: DMA Disable on Reception Error**

0: DMA is not disabled in case of reception error. The corresponding error flag is set but RXNE is kept 0 preventing from overrun. As a consequence, the DMA request is not asserted, so the erroneous data is not transferred (no DMA request), but next correct received data are transferred (used for smartcard mode).

1: DMA is disabled following a reception error. The corresponding error flag is set, as well as RXNE. The DMA request is masked until the error flag is cleared. This means that the software must first disable the DMA request (DMAR = 0) or clear RXNE before clearing the error flag.

This bit can only be written when the USART is disabled (UE=0).

*Note: The reception errors are: parity error, framing error or noise error.*

**Bit 12 OVRDIS: Overrun Disable**

This bit is used to disable the receive overrun detection.

0: Overrun Error Flag, ORE, is set when received data is not read before receiving new data.

1: Overrun functionality is disabled. If new data is received while the RXNE flag is still set the ORE flag is not set and the new received data overwrites the previous content of the USART\_RDR register.

This bit can only be written when the USART is disabled (UE=0).

*Note: This control bit allows checking the communication flow without reading the data.*

**Bit 11 ONEBIT: One sample bit method enable**

This bit allows the user to select the sample method. When the one sample bit method is selected the noise detection flag (NF) is disabled.

0: Three sample bit method

1: One sample bit method

This bit can only be written when the USART is disabled (UE=0).

*Note: ONEBIT feature applies only to data bits, It does not apply to Start bit.*

**Bit 10 CTSIE: CTS interrupt enable**

0: Interrupt is inhibited

1: An interrupt is generated whenever CTSIF=1 in the USART\_ISR register

*Note: If the hardware flow control feature is not supported, this bit is reserved and must be kept at reset value. Please refer to [Section 40.4: USART implementation on page 1323](#).*

**Bit 9 CTSE: CTS enable**

0: CTS hardware flow control disabled

1: CTS mode enabled, data is only transmitted when the CTS input is deasserted (tied to 0). If the CTS input is asserted while data is being transmitted, then the transmission is completed before stopping. If data is written into the data register while CTS is asserted, the transmission is postponed until CTS is deasserted.

This bit can only be written when the USART is disabled (UE=0)

*Note: If the hardware flow control feature is not supported, this bit is reserved and must be kept at reset value. Please refer to [Section 40.4: USART implementation on page 1323](#).*

**Bit 8 RTSE:** RTS enable

0: RTS hardware flow control disabled

1: RTS output enabled, data is only requested when there is space in the receive buffer. The transmission of data is expected to cease after the current character has been transmitted. The RTS output is deasserted (pulled to 0) when data can be received.

This bit can only be written when the USART is disabled (UE=0).

*Note: If the hardware flow control feature is not supported, this bit is reserved and must be kept at reset value. Please refer to [Section 40.4: USART implementation on page 1323](#).*

**Bit 7 DMAT:** DMA enable transmitter

This bit is set/reset by software

1: DMA mode is enabled for transmission

0: DMA mode is disabled for transmission

**Bit 6 DMAR:** DMA enable receiver

This bit is set/reset by software

1: DMA mode is enabled for reception

0: DMA mode is disabled for reception

**Bit 5 SCEN:** Smartcard mode enable

This bit is used for enabling smartcard mode.

0: Smartcard mode disabled

1: Smartcard mode enabled

This bit field can only be written when the USART is disabled (UE=0).

*Note: If the USART does not support smartcard mode, this bit is reserved and must be kept at reset value. Please refer to [Section 40.4: USART implementation on page 1323](#).*

**Bit 4 NACK:** Smartcard NACK enable

0: NACK transmission in case of parity error is disabled

1: NACK transmission during parity error is enabled

This bit field can only be written when the USART is disabled (UE=0).

*Note: If the USART does not support smartcard mode, this bit is reserved and must be kept at reset value. Please refer to [Section 40.4: USART implementation on page 1323](#).*

**Bit 3 HDSEL:** Half-duplex selection

Selection of single-wire half-duplex mode

0: Half-duplex mode is not selected

1: Half-duplex mode is selected

This bit can only be written when the USART is disabled (UE=0).

**Bit 2 IRLP:** IrDA low-power

This bit is used for selecting between normal and low-power IrDA modes

0: Normal mode

1: Low-power mode

This bit can only be written when the USART is disabled (UE=0).

*Note: If IrDA mode is not supported, this bit is reserved and must be kept at reset value.  
Please refer to [Section 40.4: USART implementation on page 1323](#).*

**Bit 1 IREN:** IrDA mode enable

This bit is set and cleared by software.

0: IrDA disabled

1: IrDA enabled

This bit can only be written when the USART is disabled (UE=0).

*Note: If IrDA mode is not supported, this bit is reserved and must be kept at reset value.  
Please refer to [Section 40.4: USART implementation on page 1323](#).*

**Bit 0 EIE:** Error interrupt enable

Error Interrupt Enable Bit is required to enable interrupt generation in case of a framing error, overrun error or noise flag (FE=1 or ORE=1 or NF=1 in the USART\_ISR register).

0: Interrupt is inhibited

1: An interrupt is generated when FE=1 or ORE=1 or NF=1 in the USART\_ISR register.

**40.8.4 USART baud rate register (USART\_BRR)**

This register can only be written when the USART is disabled (UE=0). It may be automatically updated by hardware in auto baud rate detection mode.

Address offset: 0x0C

Reset value: 0x0000 0000

|           |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|-----------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| 31        | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |

| BRR[15:0] |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| rw        | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   |

Bits 31:16 Reserved, must be kept at reset value.

**Bits 15:4 BRR[15:4]**

BRR[15:4] = USARTDIV[15:4]

**Bits 3:0 BRR[3:0]**

When OVER8 = 0, BRR[3:0] = USARTDIV[3:0].

When OVER8 = 1:

BRR[2:0] = USARTDIV[3:0] shifted 1 bit to the right.

BRR[3] must be kept cleared.

**40.8.5 USART guard time and prescaler register (USART\_GTPR)**

Address offset: 0x10

Reset value: 0x0000 0000

|         |      |      |      |      |      |      |      |          |      |      |      |      |      |      |      |

| 31      | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23       | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Res.    | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.     | Res. | Res. | Res. | Res. | Res. | Res. | Res. |
|         |      |      |      |      |      |      |      |          |      |      |      |      |      |      |      |
| 15      | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7        | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| GT[7:0] |      |      |      |      |      |      |      | PSC[7:0] |      |      |      |      |      |      |      |
| rw      | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw       | rw   | rw   | rw   | rw   | rw   | rw   | rw   |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:8 **GT[7:0]**: Guard time value

This bit-field is used to program the Guard time value in terms of number of baud clock periods.

This is used in smartcard mode. The Transmission Complete flag is set after this guard time value.

This bit field can only be written when the USART is disabled (UE=0).

*Note: If smartcard mode is not supported, this bit is reserved and must be kept at reset value. Please refer to [Section 40.4: USART implementation on page 1323](#).*

Bits 7:0 **PSC[7:0]**: Prescaler value

**In IrDA Low-power and normal IrDA mode:**

PSC[7:0] = IrDA normal and low-power baud rate

Used for programming the prescaler for dividing the USART source clock to achieve the low-power frequency:

The source clock is divided by the value given in the register (8 significant bits):

00000000: Reserved - do not program this value

00000001: divides the source clock by 1

00000010: divides the source clock by 2

...

**In smartcard mode:**

PSC[4:0]: Prescaler value

Used for programming the prescaler for dividing the USART source clock to provide the smartcard clock.

The value given in the register (5 significant bits) is multiplied by 2 to give the division factor of the source clock frequency:

00000: Reserved - do not program this value

00001: divides the source clock by 2

00010: divides the source clock by 4

00011: divides the source clock by 6

...

This bit field can only be written when the USART is disabled (UE=0).

*Note: Bits [7:5] must be kept at reset value if smartcard mode is used.*

*This bit field is reserved and must be kept at reset value when the smartcard and IrDA modes are not supported. Please refer to [Section 40.4: USART implementation on page 1323](#).*

## 40.8.6 USART receiver timeout register (USART\_RTOR)

Address offset: 0x14

Reset value: 0x0000 0000

|           |    |    |    |    |    |    |    |            |    |    |    |    |    |    |    |
|-----------|----|----|----|----|----|----|----|------------|----|----|----|----|----|----|----|
| 31        | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23         | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| BLEN[7:0] |    |    |    |    |    |    |    | RTO[23:16] |    |    |    |    |    |    |    |
| rw        | rw | rw | rw | rw | rw | rw | rw | rw         | rw | rw | rw | rw | rw | rw | rw |
| 15        | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7          | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| RTO[15:0] |    |    |    |    |    |    |    |            |    |    |    |    |    |    |    |
| rw        | rw | rw | rw | rw | rw | rw | rw | rw         | rw | rw | rw | rw | rw | rw | rw |

Bits 31:24 **BLEN[7:0]**: Block Length

This bit-field gives the Block length in smartcard T=1 Reception. Its value equals the number of information characters + the length of the Epilogue Field (1-LEC/2-CRC) - 1.

Examples:

BLEN = 0 -> 0 information characters + LEC

BLEN = 1 -> 0 information characters + CRC

BLEN = 255 -> 254 information characters + CRC (total 256 characters))

In smartcard mode, the Block length counter is reset when TXE=0.

This bit-field can be used also in other modes. In this case, the Block length counter is reset when RE=0 (receiver disabled) and/or when the EOBCF bit is written to 1.

*Note: This value can be programmed after the start of the block reception (using the data from the LEN character in the Prologue Field). It must be programmed only once per received block.*

Bits 23:0 **RTO[23:0]**: Receiver timeout value

This bit-field gives the Receiver timeout value in terms of number of bit duration.

In standard mode, the RTOF flag is set if, after the last received character, no new start bit is detected for more than the RTO value.

In smartcard mode, this value is used to implement the CWT and BWT. See smartcard section for more details.

In this case, the timeout measurement is done starting from the Start Bit of the last received character.

*Note: This value must only be programmed once per received character.*

*Note: RTOR can be written on the fly. If the new value is lower than or equal to the counter, the RTOF flag is set.*

*This register is reserved and forced by hardware to "0x00000000" when the Receiver timeout feature is not supported. Please refer to [Section 40.4: USART implementation on page 1323](#).*

### 40.8.7 USART request register (USART\_RQR)

Address offset: 0x18

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |      |      |       |       |      |       |       |
|------|------|------|------|------|------|------|------|------|------|------|-------|-------|------|-------|-------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20    | 19    | 18   | 17    | 16    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.  | Res.  | Res. | Res.  | Res.  |
|      |      |      |      |      |      |      |      |      |      |      |       |       |      |       |       |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4     | 3     | 2    | 1     | 0     |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | TXFRQ | RXFRQ | MMRQ | SBKRQ | ABRRQ |
|      |      |      |      |      |      |      |      |      |      |      | w     | w     | w    | w     | w     |

Bits 31:5 Reserved, must be kept at reset value.

**Bit 4 TXFRQ:** Transmit data flush request

Writing 1 to this bit sets the TXE flag.

This allows to discard the transmit data. This bit must be used only in smartcard mode, when data has not been sent due to errors (NACK) and the FE flag is active in the USART\_ISR register.

If the USART does not support smartcard mode, this bit is reserved and must be kept at reset value. Please refer to [Section 40.4: USART implementation on page 1323](#).

**Bit 3 RXFRQ:** Receive data flush request

Writing 1 to this bit clears the RXNE flag.

This allows to discard the received data without reading it, and avoid an overrun condition.

**Bit 2 MMRQ:** Mute mode request

Writing 1 to this bit puts the USART in mute mode and sets the RWU flag.

**Bit 1 SBKRQ:** Send break request

Writing 1 to this bit sets the SBKF flag and request to send a BREAK on the line, as soon as the transmit machine is available.

*Note:* In the case the application needs to send the break character following all previously inserted data, including the ones not yet transmitted, the software should wait for the TXE flag assertion before setting the SBKRQ bit.

**Bit 0 ABRRQ:** Auto baud rate request

Writing 1 to this bit resets the ABRF and ABRE flags in the USART\_ISR and request an automatic baud rate measurement on the next received data frame.

*Note:* If the USART does not support the auto baud rate feature, this bit is reserved and must be kept at reset value. Please refer to [Section 40.4: USART implementation on page 1323](#).

## 40.8.8 USART interrupt and status register (USART\_ISR)

Address offset: 0x1C

Reset value: 0x0200 00C0

|      |      |      |      |      |      |       |      |      |       |       |      |     |      |     |      |
|------|------|------|------|------|------|-------|------|------|-------|-------|------|-----|------|-----|------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25    | 24   | 23   | 22    | 21    | 20   | 19  | 18   | 17  | 16   |
| Res. | Res. | Res. | Res. | Res. | Res. | TCBGT | Res. | Res. | REACK | TEACK | WUF  | RWU | SBKF | CMF | BUSY |
|      |      |      |      |      |      | r     |      |      | r     | r     | r    | r   | r    | r   | r    |
| 15   | 14   | 13   | 12   | 11   | 10   | 9     | 8    | 7    | 6     | 5     | 4    | 3   | 2    | 1   | 0    |
| ABRF | ABRE | Res. | EOBF | RTOF | CTS  | CTSIF | LBDF | TXE  | TC    | RXNE  | IDLE | ORE | NF   | FE  | PE   |
| r    | r    |      | r    | r    | r    | r     | r    | r    | r     | r     | r    | r   | r    | r   | r    |

Bits 31:26 Reserved, must be kept at reset value.

Bit 25 **TCBGT**: Transmission complete before guard time completion.

This bit is used in smartcard mode. It is set by hardware if the transmission of a frame containing data has completed successfully (no NACK received from the card) and before the guard time has elapsed (contrary to the TC flag which is set when the guard time has elapsed).

An interrupt is generated if TCBGTIE=1 in USART\_CR3 register. It is cleared by software, by writing 1 to TCBGTCF in USART\_ICR or by writing to the USART\_TDR register.

0: Transmission not complete or transmission completed with error (i.e. NACK received from the card)

1: Transmission complete (before Guard time has elapsed and no NACK received from the smartcard).

*Note: If the USART does not support the smartcard mode, this bit is reserved and must be kept at reset value. If the USART supports the smartcard mode and the smartcard mode is enabled, the TCBGT reset value is 1.*

*Note: This bit is available on STM32L49x/L4Ax devices only*

Bits 24:23 Reserved, must be kept at reset value.

Bit 22 **REACK**: Receive enable acknowledge flag

This bit is set/reset by hardware, when the Receive Enable value is taken into account by the USART.

When the wake-up from Stop mode is supported, the REACK flag can be used to verify that the USART is ready for reception before entering Stop mode.

Bit 21 **TEACK**: Transmit enable acknowledge flag

This bit is set/reset by hardware, when the Transmit Enable value is taken into account by the USART.

It can be used when an idle frame request is generated by writing TE=0, followed by TE=1 in the USART\_CR1 register, in order to respect the TE=0 minimum period.

Bit 20 **WUF**: Wake-up from Stop mode flag

This bit is set by hardware, when a wake-up event is detected. The event is defined by the WUS bit field. It is cleared by software, writing a 1 to the WUCF in the USART\_ICR register.

An interrupt is generated if WUFIE=1 in the USART\_CR3 register.

*Note: When UESM is cleared, WUF flag is also cleared.*

*The WUF interrupt is active only in Stop mode.*

*If the USART does not support the wake-up from Stop feature, this bit is reserved and kept at reset value.*

**Bit 19 RWU:** Receiver wake-up from mute mode

This bit indicates if the USART is in mute mode. It is cleared/set by hardware when a wake-up/mute sequence is recognized. The mute mode control sequence (address or IDLE) is selected by the WAKE bit in the USART\_CR1 register.

When wake-up on Idle mode is selected, this bit can only be set by software, writing 1 to the MMRQ bit in the USART\_RQR register.

0: Receiver in active mode

1: Receiver in mute mode

**Bit 18 SBKF:** Send break flag

This bit indicates that a send break character was requested. It is set by software, by writing 1 to the SBKRQ bit in the USART\_RQR register. It is automatically reset by hardware during the stop bit of break transmission.

0: No break character is transmitted

1: Break character is transmitted

**Bit 17 CMF:** Character match flag

This bit is set by hardware, when the character defined by ADD[7:0] is received. It is cleared by software, writing 1 to the CMCF in the USART\_ICR register.

An interrupt is generated if CMIE=1 in the USART\_CR1 register.

0: No Character match detected

1: Character Match detected

**Bit 16 BUSY:** Busy flag

This bit is set and reset by hardware. It is active when a communication is ongoing on the RX line (successful start bit detected). It is reset at the end of the reception (successful or not).

0: USART is idle (no reception)

1: Reception on going

**Bit 15 ABRF:** Auto baud rate flag

This bit is set by hardware when the automatic baud rate has been set (RXNE will also be set, generating an interrupt if RXNEIE = 1) or when the auto baud rate operation was completed without success (ABRE=1) (ABRE, RXNE and FE are also set in this case)

It is cleared by software, in order to request a new auto baud rate detection, by writing 1 to the ABRRQ in the USART\_RQR register.

*Note: If the USART does not support the auto baud rate feature, this bit is reserved and kept at reset value.*

**Bit 14 ABRE:** Auto baud rate error

This bit is set by hardware if the baud rate measurement failed (baud rate out of range or character comparison failed)

It is cleared by software, by writing 1 to the ABRRQ bit in the USART\_RQR register.

*Note: If the USART does not support the auto baud rate feature, this bit is reserved and kept at reset value.*

**Bit 13** Reserved, must be kept at reset value.

**Bit 12 EOBF:** End of block flag

This bit is set by hardware when a complete block has been received (for example T=1 smartcard mode). The detection is done when the number of received bytes (from the start of the block, including the prologue) is equal or greater than BLEN + 4.

An interrupt is generated if EOBI = 1 in the USART\_CR1 register.

It is cleared by software, writing 1 to EOBCF in the USART\_ICR register.

0: End of Block not reached

1: End of Block (number of characters) reached

*Note: If smartcard mode is not supported, this bit is reserved and kept at reset value. Please refer to [Section 40.4: USART implementation on page 1323](#).*

**Bit 11 RTOF:** Receiver timeout

This bit is set by hardware when the timeout value, programmed in the RTOR register has lapsed, without any communication. It is cleared by software, writing 1 to the RTOCF bit in the USART\_ICR register.

An interrupt is generated if RTOIE=1 in the USART\_CR1 register.

In smartcard mode, the timeout corresponds to the CWT or BWT timings.

0: Timeout value not reached

1: Timeout value reached without any data reception

*Note: If a time equal to the value programmed in RTOR register separates 2 characters, RTOF is not set. If this time exceeds this value + 2 sample times (2/16 or 2/8, depending on the oversampling method), RTOF flag is set.*

*The counter counts even if RE = 0 but RTOF is set only when RE = 1. If the timeout has already elapsed when RE is set, then RTOF is set.*

*If the USART does not support the Receiver timeout feature, this bit is reserved and kept at reset value.*

**Bit 10 CTS:** CTS flag

This bit is set/reset by hardware. It is an inverted copy of the status of the CTS input pin.

0: CTS line set

1: CTS line reset

*Note: If the hardware flow control feature is not supported, this bit is reserved and kept at reset value.*

**Bit 9 CTSIF:** CTS interrupt flag

This bit is set by hardware when the CTS input toggles, if the CTSE bit is set. It is cleared by software, by writing 1 to the CTSCF bit in the USART\_ICR register.

An interrupt is generated if CTSIE=1 in the USART\_CR3 register.

0: No change occurred on the CTS status line

1: A change occurred on the CTS status line

*Note: If the hardware flow control feature is not supported, this bit is reserved and kept at reset value.*

**Bit 8 LBDF:** LIN break detection flag

This bit is set by hardware when the LIN break is detected. It is cleared by software, by writing 1 to the LBD CF in the USART\_ICR.

An interrupt is generated if LBDIE = 1 in the USART\_CR2 register.

0: LIN Break not detected

1: LIN break detected

*Note: If the USART does not support LIN mode, this bit is reserved and kept at reset value. Please refer to [Section 40.4: USART implementation on page 1323](#).*

**Bit 7 TXE:** Transmit data register empty

This bit is set by hardware when the content of the USART\_TDR register has been transferred into the shift register. It is cleared by a write to the USART\_TDR register.  
 The TXE flag can also be cleared by writing 1 to the TXFRQ in the USART\_RQR register, in order to discard the data (only in smartcard T=0 mode, in case of transmission failure).  
 An interrupt is generated if the TXEIE bit =1 in the USART\_CR1 register.  
 0: data is not transferred to the shift register  
 1: data is transferred to the shift register)

*Note: This bit is used during single buffer transmission.*

**Bit 6 TC:** Transmission complete

This bit is set by hardware if the transmission of a frame containing data is complete and if TXE is set. An interrupt is generated if TCIE=1 in the USART\_CR1 register. It is cleared by software, writing 1 to the TCCF in the USART\_ICR register or by a write to the USART\_TDR register.  
 An interrupt is generated if TCIE=1 in the USART\_CR1 register.  
 0: Transmission is not complete  
 1: Transmission is complete

*Note: If TE bit is reset and no transmission is on going, the TC bit is set immediately.*

**Bit 5 RXNE:** Read data register not empty

This bit is set by hardware when the content of the RDR shift register has been transferred to the USART\_RDR register. It is cleared by a read to the USART\_RDR register. The RXNE flag can also be cleared by writing 1 to the RXFRQ in the USART\_RQR register.  
 An interrupt is generated if RXNEIE=1 in the USART\_CR1 register.  
 0: data is not received  
 1: Received data is ready to be read.

**Bit 4 IDLE:** Idle line detected

This bit is set by hardware when an Idle line is detected. An interrupt is generated if IDLEIE = 1 in the USART\_CR1 register. It is cleared by software, writing 1 to the IDLECF in the USART\_ICR register.  
 0: No Idle line is detected  
 1: Idle line is detected

*Note: The IDLE bit will not be set again until the RXNE bit has been set (i.e. a new idle line occurs).*

*If mute mode is enabled (MME=1), IDLE is set if the USART is not mute (RWU=0), whatever the mute mode selected by the WAKE bit. If RWU=1, IDLE is not set.*

**Bit 3 ORE:** Overrun error

This bit is set by hardware when the data currently being received in the shift register is ready to be transferred into the RDR register while RXNE=1. It is cleared by a software, writing 1 to the ORECF, in the USART\_ICR register.  
 An interrupt is generated if RXNEIE=1 in the USART\_CR1 register, or EIE = 1 in the USART\_CR3 register.  
 0: No overrun error  
 1: Overrun error is detected

*Note: When this bit is set, the RDR register content is not lost but the shift register is overwritten. An interrupt is generated if the ORE flag is set during multibuffer communication if the EIE bit is set.*

*This bit is permanently forced to 0 (no overrun detection) when the OVRDIS bit is set in the USART\_CR3 register.*

Bit 2 **NF**: START bit Noise detection flag

This bit is set by hardware when noise is detected on a received frame. It is cleared by software, writing 1 to the NFCF bit in the USART\_ICR register.

0: No noise is detected

1: Noise is detected

*Note: This bit does not generate an interrupt as it appears at the same time as the RXNE bit which itself generates an interrupt. An interrupt is generated when the NF flag is set during multibuffer communication if the EIE bit is set.*

*Note: When the line is noise-free, the NF flag can be disabled by programming the ONEBIT bit to 1 to increase the USART tolerance to deviations (Refer to [Section 40.5.5: Tolerance of the USART receiver to clock deviation on page 1339](#)).*

Bit 1 **FE**: Framing error

This bit is set by hardware when a de-synchronization, excessive noise or a break character is detected. It is cleared by software, writing 1 to the FECF bit in the USART\_ICR register.

In smartcard mode, in transmission, this bit is set when the maximum number of transmit attempts is reached without success (the card NACKs the data frame).

An interrupt is generated if EIE = 1 in the USART\_CR3 register.

0: No Framing error is detected

1: Framing error or break character is detected

Bit 0 **PE**: Parity error

This bit is set by hardware when a parity error occurs in receiver mode. It is cleared by software, writing 1 to the PECF in the USART\_ICR register.

An interrupt is generated if PEIE = 1 in the USART\_CR1 register.

0: No parity error

1: Parity error

## 40.8.9 USART interrupt flag clear register (USART\_ICR)

Address offset: 0x20

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 **WUCF**: Wake-up from Stop mode clear flag

Writing 1 to this bit clears the WUF flag in the USART\_ISR register.

*Note: If the USART does not support the wake-up from Stop feature, this bit is reserved and must be kept at reset value.*

Bits 19:18 Reserved, must be kept at reset value.

Bit 17 **CMCF**: Character match clear flag

Writing 1 to this bit clears the CMF flag in the USART\_ISR register.

Bits 16:13 Reserved, must be kept at reset value.

Bit 12 **EOBCF**: End of block clear flag

Writing 1 to this bit clears the EOBF flag in the USART\_ISR register.

*Note: If the USART does not support smartcard mode, this bit is reserved and must be kept at reset value. Please refer to [Section 40.4: USART implementation on page 1323](#).*

Bit 11 **RTOCF**: Receiver timeout clear flag

Writing 1 to this bit clears the RTOF flag in the USART\_ISR register.

*Note: If the USART does not support the Receiver timeout feature, this bit is reserved and must be kept at reset value. Please refer to [Section 40.4: USART implementation on page 1323](#).*

Bit 10 Reserved, must be kept at reset value.

Bit 9 **CTSCF**: CTS clear flag

Writing 1 to this bit clears the CTSIF flag in the USART\_ISR register.

*Note: If the hardware flow control feature is not supported, this bit is reserved and must be kept at reset value. Please refer to [Section 40.4: USART implementation on page 1323](#).*

Bit 8 **LBDCF**: LIN break detection clear flag

Writing 1 to this bit clears the LBDF flag in the USART\_ISR register.

*Note: If LIN mode is not supported, this bit is reserved and must be kept at reset value. Please refer to [Section 40.4: USART implementation on page 1323](#).*

Bit 7 **TCBGTCF**: Transmission completed before guard time clear flag

Writing 1 to this bit clears the TCBGT flag in the USART\_ISR register.

*Note: If the USART does not support smartcard mode, this bit is reserved and forced by hardware to 0. Please refer to [Section 40.4: USART implementation on page 1323](#).*

*Note: This bit is available on STM32L49x/L4Ax devices only*

Bit 6 **TCCF**: Transmission complete clear flag

Writing 1 to this bit clears the TC flag in the USART\_ISR register.

Bit 5 Reserved, must be kept at reset value.

Bit 4 **IDLECF**: Idle line detected clear flag

Writing 1 to this bit clears the IDLE flag in the USART\_ISR register.

Bit 3 **ORECF**: Overrun error clear flag

Writing 1 to this bit clears the ORE flag in the USART\_ISR register.

Bit 2 **NCF**: Noise detected clear flag

Writing 1 to this bit clears the NF flag in the USART\_ISR register.

Bit 1 **FECF**: Framing error clear flag

Writing 1 to this bit clears the FE flag in the USART\_ISR register.

Bit 0 **PECF**: Parity error clear flag

Writing 1 to this bit clears the PE flag in the USART\_ISR register.

### 40.8.10 USART receive data register (USART\_RDR)

Address offset: 0x24

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |          |      |      |      |      |      |      |      |      |

| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8        | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | RDR[8:0] |      |      |      |      |      |      |      |      |
|      |      |      |      |      |      |      | r        | r    | r    | r    | r    | r    | r    | r    | r    |

Bits 31:9 Reserved, must be kept at reset value.

Bits 8:0 **RDR[8:0]**: Receive data value

Contains the received data character.

The RDR register provides the parallel interface between the input shift register and the internal bus (see [Figure 420](#)).

When receiving with the parity enabled, the value read in the MSB bit is the received parity bit.

### 40.8.11 USART transmit data register (USART\_TDR)

Address offset: 0x28

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |          |      |      |      |      |      |      |      |      |
|------|------|------|------|------|------|------|----------|------|------|------|------|------|------|------|------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24       | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.     | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. |
|      |      |      |      |      |      |      |          |      |      |      |      |      |      |      |      |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8        | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | TDR[8:0] |      |      |      |      |      |      |      |      |
|      |      |      |      |      |      |      | rw       | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   |

Bits 31:9 Reserved, must be kept at reset value.

Bits 8:0 **TDR[8:0]**: Transmit data value

Contains the data character to be transmitted.

The TDR register provides the parallel interface between the internal bus and the output shift register (see [Figure 420](#)).

When transmitting with the parity enabled (PCE bit set to 1 in the USART\_CR1 register), the value written in the MSB (bit 7 or bit 8 depending on the data length) has no effect because it is replaced by the parity.

*Note: This register must be written only when TXE=1.*

## 40.8.12 USART register map

The table below gives the USART register map and reset values.

Table 255. USART register map and reset values

| Offset | Register name<br>reset value | 31        | 30  | 29  | 28  | 27       | 26    | 25    | 24      | 23        | 22      | 21      | 20    | 19          | 18      | 17    | 16    | 15        | 14    | 13        | 12     | 11     | 10       | 9     | 8        | 7       | 6      | 5      | 4      | 3     | 2    | 1     | 0     |   |  |  |

## 41 Low-power universal asynchronous receiver transmitter (LPUART)

### 41.1 Introduction

The low-power universal asynchronous receiver transmitter (LPUART) is an UART which allows Full-duplex UART communications with a limited power consumption. Only 32.768 kHz LSE clock is required to allow UART communications up to 9600 baud. Higher baud rates can be reached when the LPUART is clocked by clock sources different from the LSE clock.

Even when the microcontroller is in Stop mode, the LPUART can wait for an incoming UART frame while having an extremely low energy consumption. The LPUART includes all necessary hardware support to make asynchronous serial communications possible with minimum power consumption.

It supports half-duplex single-wire communications and modem operations (CTS/RTS).

It also supports multiprocessor communications.

DMA (direct memory access) can be used for data transmission/reception.

## 41.2 LPUART main features

- Full-duplex asynchronous communications
- NRZ standard format (mark/space)
- Programmable baud rate from 300 baud to 9600 baud using a 32.768 kHz clock source. Higher baud rates can be achieved by using a higher frequency clock source
- Dual clock domain allowing
  - UART functionality and wake-up from Stop mode
  - Convenient baud rate programming independent from the PCLK reprogramming
- Programmable data word length (7 or 8 or 9 bits)
- Programmable data order with MSB-first or LSB-first shifting
- Configurable stop bits (1 or 2 stop bits)
- Single-wire half-duplex communications
- Continuous communications using DMA
- Received/transmitted bytes are buffered in reserved SRAM using centralized DMA.
- Separate enable bits for transmitter and receiver
- Separate signal polarity control for transmission and reception
- Swappable Tx/Rx pin configuration
- Hardware flow control for modem and RS-485 transceiver
- Transfer detection flags:
  - Receive buffer full
  - Transmit buffer empty
  - Busy and end of transmission flags
- Parity control:
  - Transmits parity bit
  - Checks parity of received data byte
- Four error detection flags:
  - Overrun error
  - Noise detection
  - Frame error
  - Parity error
- Fourteen interrupt sources with flags
- Multiprocessor communications
  - The LPUART enters mute mode if the address does not match.
- Wake-up from mute mode (by idle line detection or address mark detection)

## 41.3 LPUART implementation

The STM32L47x/L48x/L49x/L4Ax devices embed one LPUART. Refer to [Section 40.4: USART implementation](#) for LPUART supported features.

The STM32L47x/L48x/L49x/L4Ax devices embed 3 USARTs, 2 UARTs and 1 LPUART. The [Table 247](#) describes the features supported by each peripheral.

Table 256. STM32L47x/L48x/L49x/L4Ax USART/UART/LPUART features

| USART modes/features <sup>(1)</sup>          | USART1                          | USART2 | USART3 | UART4 | UART5 | LPUART1 |

1. X = supported.

2. In 7-bit data length mode, Smartcard mode, LIN master mode and Auto baud rate (0x7F and 0x55 frames) detection are not supported.

## 41.4 LPUART functional description

Any LPUART bidirectional communication requires a minimum of two pins: Receive data In (RX) and Transmit data Out (TX):

- **RX:** Receive data Input.  
This is the serial data input.
- **TX:** Transmit data Output.  
When the transmitter is disabled, the output pin returns to its I/O port configuration.  
When the transmitter is enabled and nothing is to be transmitted, the TX pin is at high level. In single-wire mode, this I/O is used to transmit and receive the data.

Through these pins, serial data is transmitted and received in normal LPUART mode as frames comprising:

- An Idle Line prior to transmission or reception
- A start bit
- A data word (7 or 8 or 9 bits) least significant bit first
- 1, 2 stop bits indicating that the frame is complete
- The LPUART interface uses a baud rate generator
- A status register (LPUART\_ISR)
- Receive and transmit data registers (LPUART\_RDR, LPUART\_TDR)
- A baud rate register (LPUART\_BRR)

Refer to [Section 41.7: LPUART registers](#) for the definitions of each bit.

The following pins are required in RS232 hardware flow control mode:

- **CTS**: Clear To Send blocks the data transmission at the end of the current transfer when high
- **RTS**: Request to send indicates that the LPUART is ready to receive data (when low).

The following pin is required in RS485 hardware control mode:

- **DE**: Driver Enable activates the transmission mode of the external transceiver.

*Note:* **DE** and **RTS** share the same pin.

**Figure 445. LPUART block diagram**

#### 41.4.1 LPUART character description

Word length may be selected as being either 7 or 8 or 9 bits by programming the M[1:0] bits in the LPUART\_CR1 register (see [Figure 446](#)).

- 7-bit character length: M[1:0] = 10
- 8-bit character length: M[1:0] = 00
- 9-bit character length: M[1:0] = 01

By default, the signal (TX or RX) is in low state during the start bit. It is in high state during the stop bit.

These values can be inverted, separately for each signal, through polarity configuration control.

An **Idle character** is interpreted as an entire frame of “1”s. (The number of “1”s includes the number of stop bits).

A **Break character** is interpreted on receiving “0”s for a frame period. At the end of the break frame, the transmitter inserts 2 stop bits.

Transmission and reception are driven by a common baud rate generator, the clock for each is generated when the enable bit is set respectively for the transmitter and receiver.

The details of each block is given below.

Figure 446. Word length programming

### 41.4.2 LPUART transmitter

The transmitter can send data words of either 7 or 8 or 9 bits depending on the M bits status. The Transmit Enable bit (TE) must be set in order to activate the transmitter function. The data in the transmit shift register is output on the TX pin.

#### Character transmission

During an LPUART transmission, data shifts out least significant bit first (default configuration) on the TX pin. In this mode, the LPUART\_TDR register consists of a buffer (TDR) between the internal bus and the transmit shift register (see [Figure 420](#)).

Every character is preceded by a start bit which is a logic level low for one bit period. The character is terminated by a configurable number of stop bits.

The following stop bits are supported by LPUART: 1 and 2 stop bits.

**Note:** *The TE bit must be set before writing the data to be transmitted to the LPUART\_TDR.  
The TE bit should not be reset during transmission of data. Resetting the TE bit during the transmission will corrupt the data on the TX pin as the baud rate counters will get frozen.  
The current data being transmitted will be lost.  
An idle frame will be sent after the TE bit is enabled.*

#### Configurable stop bits

The number of stop bits to be transmitted with every character can be programmed in Control register 2, bits 13,12.

- **1 stop bit:** This is the default value of number of stop bits.
- **2 stop bits:** This will be supported by normal LPUART, single-wire and modem modes.

An idle frame transmission will include the stop bits.

A break transmission will be 10 low bits (when M[1:0] = 00) or 11 low bits (when M[1:0] = 01) or 9 low bits (when M[1:0] = 10) followed by 2 stop bits. It is not possible to transmit long breaks (break of length greater than 9/10/11 low bits).

**Figure 447. Configurable stop bits**

**Character transmission procedure**

1. Program the M bits in LPUART\_CR1 to define the word length.
2. Select the desired baud rate using the LPUART\_BRR register.
3. Program the number of stop bits in LPUART\_CR2.
4. Enable the LPUART by writing the UE bit in LPUART\_CR1 register to 1.
5. Select DMA enable (DMAT) in LPUART\_CR3 if multibuffer Communication is to take place. Configure the DMA register as explained in multibuffer communication.
6. Set the TE bit in LPUART\_CR1 to send an idle frame as first transmission.
7. Write the data to send in the LPUART\_TDR register (this clears the TXE bit). Repeat this for each data to be transmitted in case of single buffer.
8. After writing the last data into the LPUART\_TDR register, wait until TC=1. This indicates that the transmission of the last frame is complete. This is required for instance when the LPUART is disabled or enters the Halt mode to avoid corrupting the last transmission.

**Single byte communication**

Clearing the TXE bit is always performed by a write to the transmit data register.

The TXE bit is set by hardware and it indicates:

- The data has been moved from the LPUART\_TDR register to the shift register and the data transmission has started.
- The LPUART\_TDR register is empty.
- The next data can be written in the LPUART\_TDR register without overwriting the previous data.

This flag generates an interrupt if the TXEIE bit is set.

When a transmission is taking place, a write instruction to the LPUART\_TDR register stores the data in the TDR register; next, the data is copied in the shift register at the end of the currently ongoing transmission.

When no transmission is taking place, a write instruction to the LPUART\_TDR register places the data in the shift register, the data transmission starts, and the TXE bit is set.

If a frame is transmitted (after the stop bit) and the TXE bit is set, the TC bit goes high. An interrupt is generated if the TCIE bit is set in the LPUART\_CR1 register.

After writing the last data in the LPUART\_TDR register, it is mandatory to wait for TC=1 before disabling the LPUART or causing the microcontroller to enter the low-power mode (see [Figure 423: TC/TXE behavior when transmitting](#)).

Figure 448. TC/TXE behavior when transmitting

### Break characters

Setting the SBKRQ bit transmits a break character. The break frame length depends on the M bits (see [Figure 446](#)).

If a '1' is written to the SBKRQ bit, a break character is sent on the TX line after completing the current character transmission. The SBKF bit is set by the write operation and it is reset by hardware when the break character is completed (during the stop bits after the break character). The LPUART inserts a logic 1 signal (STOP) for the duration of 2 bits at the end of the break frame to guarantee the recognition of the start bit of the next frame.

In the case the application needs to send the break character following all previously inserted data, including the ones not yet transmitted, the software should wait for the TXE flag assertion before setting the SBKRQ bit.

### Idle characters

Setting the TE bit drives the LPUART to send an idle frame before the first data frame.

#### 41.4.3 LPUART receiver

The LPUART can receive data words of either 7 or 8 or 9 bits depending on the M bits in the LPUART\_CR1 register.

#### Start bit detection

In LPUART, for START bit detection, a falling edge should be detected first on the Rx line, then a sample is taken in the middle of the start bit to confirm that it is still '0'. If the start sample is at '1', then the noise error flag (NF) is set, then the START bit is discarded and the receiver waits for a new START bit. Else, the receiver continues to sample all incoming bits normally.

### Character reception

During an LPUART reception, data shifts in least significant bit first (default configuration) through the RX pin. In this mode, the LPUART\_RDR register consists of a buffer (RDR) between the internal bus and the received shift register.

#### Character reception procedure

1. Program the M bits in LPUART\_CR1 to define the word length.
2. Select the desired baud rate using the baud rate register LPUART\_BRR
3. Program the number of stop bits in LPUART\_CR2.
4. Enable the LPUART by writing the UE bit in LPUART\_CR1 register to 1.
5. Select DMA enable (DMAR) in LPUART\_CR3 if multibuffer communication is to take place. Configure the DMA register as explained in multibuffer communication.
6. Set the RE bit LPUART\_CR1. This enables the receiver which begins searching for a start bit.

When a character is received

- The RXNE bit is set. It indicates that the content of the shift register is transferred to the RDR. In other words, data has been received and can be read (as well as its associated error flags).
- An interrupt is generated if the RXNEIE bit is set.
- The error flags can be set if a frame error, noise or an overrun error has been detected during reception. PE flag can also be set with RXNE.
- In multibuffer, RXNE is set after every byte received and is cleared by the DMA read of the Receive data Register.
- In single buffer mode, clearing the RXNE bit is performed by a software read to the LPUART\_RDR register. The RXNE flag can also be cleared by writing 1 to the RXFRQ in the LPUART\_RQR register. The RXNE bit must be cleared before the end of the reception of the next character to avoid an overrun error.

### Break character

When a break character is received, the LPUART handles it as a framing error.

### Idle character

When an idle frame is detected, there is the same procedure as for a received data character plus an interrupt if the IDLEIE bit is set.

### Overrun error

An overrun error occurs when a character is received when RXNE has not been reset. Data can not be transferred from the shift register to the RDR register until the RXNE bit is cleared.

The RXNE flag is set after every byte received. An overrun error occurs if RXNE flag is set when the next data is received or the previous DMA request has not been serviced. When an overrun error occurs:

- The ORE bit is set.
- The RDR content will not be lost. The previous data is available when a read to LPUART\_RDR is performed.
- The shift register will be overwritten. After that point, any data received during overrun is lost.
- An interrupt is generated if either the RXNEIE bit is set or EIE bit is set.
- The ORE bit is reset by setting the ORECF bit in the ICR register.

*Note: The ORE bit, when set, indicates that at least 1 data has been lost. There are two possibilities:*

- if  $RXNE=1$ , then the last valid data is stored in the receive register RDR and can be read,
- if  $RXNE=0$ , then it means that the last valid data has already been read and thus there is nothing to be read in the RDR. This case can occur when the last valid data is read in the RDR at the same time as the new (and lost) data is received.

### Selecting the clock source

The choice of the clock source is done through the Reset and Clock Control system (RCC). The clock source must be chosen before enabling the LPUART (by setting the UE bit).

The choice of the clock source must be done according to two criteria:

- Possible use of the LPUART in low-power mode
- Communication speed.

The clock source frequency is  $f_{CK}$ .

When the dual clock domain and the wake-up from Stop mode features are supported, the clock source can be one of the following sources:  $f_{PCLK}$  (default),  $f_{LSE}$ ,  $f_{HSI}$  or  $f_{SYS}$ . Otherwise, the LPUART clock source is  $f_{PCLK}$ .

Choosing  $f_{LSE}$ ,  $f_{HSI}$  as clock source may allow the LPUART to receive data while the MCU is in low-power mode. Depending on the received data and wake-up mode selection, the LPUART wakes up the MCU, when needed, in order to transfer the received data by software reading the LPUART\_RDR register or by DMA.

For the other clock sources, the system must be active in order to allow LPUART communication.

The communication speed range (specially the maximum communication speed) is also determined by the clock source.

The receiver samples each incoming bit as close as possible to the middle of the bit -period. Only a single sample is taken of each of the incoming bit.

*Note: There is no noise detection for data.*

### Framing error

A framing error is detected when the stop bit is not recognized on reception at the expected time, following either a de-synchronization or excessive noise.

When the framing error is detected:

- The FE bit is set by hardware.
- The invalid data is transferred from the Shift register to the LPUART\_RDR register.
- No interrupt is generated in case of single byte communication. However this bit rises at the same time as the RXNE bit which itself generates an interrupt. In case of multibuffer communication an interrupt will be issued if the EIE bit is set in the LPUART\_CR3 register.

The FE bit is reset by writing 1 to the FECF in the LPUART\_ICR register.

### Configurable stop bits during reception

The number of stop bits to be received can be configured through the control bits of Control Register 2 - it can be either 1 or 2 in normal mode.

- **1 stop bit:** Sampling for 1 stop Bit is done on the 8th, 9th and 10th samples.
- **2 stop bits:** Sampling for the 2 stop bits is done in the middle of the second stop bit. The RXNE and FE flags are set just after this sample i.e. during the second stop bit. The first stop bit is not checked for framing error.

#### 41.4.4 LPUART baud rate generation

The baud rate for the receiver and transmitter (Rx and Tx) are both set to the same value as programmed in the LPUART\_BRR register.

$$\text{Tx/Rx baud} = \frac{256 \times f_{\text{CK}}}{\text{LPUARTDIV}}$$

LPUARTDIV is coded on the LPUART\_BRR register.

*Note: The baud counters are updated to the new value in the baud registers after a write operation to LPUART\_BRR. Hence the baud rate register value should not be changed during communication.*

*It is forbidden to write values less than 0x300 in the LPUART\_BRR register.*

*fck must be in the range [3 x baud rate, 4096 x baud rate].*

The maximum baud rate that can be reached when the LPUART clock source is the LSE, is 9600 baud. Higher baud rates can be reached when the LPUART is clocked by clock sources different than the LSE clock. For example, if the LPUART clock source is the system clock (maximum is 80 MHz), the maximum baud rate that can be reached is 26 Mbaud.

Table 257. Error calculation for programmed baud rates at  $f_{ck} = 32.768$  kHz

| Baud rate |           | $f_{ck} = 32.768$ kHz |                                            |                                                          |
|-----------|-----------|-----------------------|--------------------------------------------|----------------------------------------------------------|
| S.No      | Desired   | Actual                | Value programmed in the baud rate register | % Error = (Calculated - Desired) B.rate / Desired B.rate |
| 1         | 300 baud  | 300 baud              | 0x6D3A                                     | 0                                                        |
| 2         | 600 baud  | 600 baud              | 0x369D                                     | 0                                                        |
| 3         | 1200 baud | 1200.087 baud         | 0x1B4E                                     | 0.007                                                    |

#### 41.4.5 Tolerance of the LPUART receiver to clock deviation

The asynchronous receiver of the LPUART works correctly only if the total clock system deviation is less than the tolerance of the LPUART receiver. The causes which contribute to the total deviation are:

- DTRA: Deviation due to the transmitter error (which also includes the deviation of the transmitter's local oscillator)
- DQUANT: Error due to the baud rate quantization of the receiver
- DREC: Deviation of the receiver's local oscillator
- DTCL: Deviation due to the transmission line (generally due to the transceivers which can introduce an asymmetry between the low-to-high transition timing and the high-to-low transition timing)

$$DTRA + DQUANT + DREC + DTCL + DWU < \text{LPUART receiver tolerance}$$

where

DWU is the error due to sampling point deviation when the wake-up from Stop mode is used.

when M[1:0] = 01:

$$DWU = \frac{t_{WULPUART}}{11 \times T_{bit}}$$

when M[1:0] = 00:

$$DWU = \frac{t_{WULPUART}}{10 \times T_{bit}}$$

when M[1:0] = 10:

$$DWU = \frac{t_{WULPUART}}{9 \times T_{bit}}$$

$t_{WULPUART}$  is the time between:

- The detection of start bit falling edge
- The instant when clock (requested by the peripheral) is ready and reaching the peripheral and regulator is ready.

$t_{WULPUART}$  corresponds to  $t_{WUSTOP}$  value provided in the datasheet.

The LPUART receiver can receive data correctly at up to the maximum tolerated deviation specified in [Table 259](#):

- 7, 8 or 9-bit character length defined by the M bits in the LPUARTx\_CR1 register
- 1 or 2 stop bits

**Table 259. Tolerance of the LPUART receiver**

| M bits                    | 768 ≤ BRR < 1024 | 1024 ≤ BRR < 2048 | 2048 ≤ BRR < 4096 | 4096 ≤ BRR |
|---------------------------|------------------|-------------------|-------------------|------------|
| 8 bits (M=00), 1 stop bit | 1.82%            | 2.56%             | 3.90%             | 4.42%      |
| 9 bits (M=01), 1 stop bit | 1.69%            | 2.33%             | 2.53%             | 4.14%      |
| 7 bits (M=10), 1 stop bit | 2.08%            | 2.86%             | 4.35%             | 4.42%      |

Table 259. Tolerance of the LPUART receiver (continued)

| M bits                    | $768 \leq \text{BRR} < 1024$ | $1024 \leq \text{BRR} < 2048$ | $2048 \leq \text{BRR} < 4096$ | $4096 \leq \text{BRR}$ |
|---------------------------|------------------------------|-------------------------------|-------------------------------|------------------------|
| 8 bits (M=00), 2 stop bit | 2.08%                        | 2.86%                         | 4.35%                         | 4.42%                  |
| 9 bits (M=01), 2 stop bit | 1.82%                        | 2.56%                         | 3.90%                         | 4.42%                  |
| 7 bits (M=10), 2stop bit  | 2.34%                        | 3.23%                         | 4.92%                         | 4.42%                  |

**Note:** The data specified in [Table 259](#) may slightly differ in the special case when the received frames contain some Idle frames of exactly 10-bit durations when M bits = 00 (11-bit durations when M bits = 01 or 9-bit durations when M bits = 10).

#### 41.4.6 Multiprocessor communication using LPUART

It is possible to perform multiprocessor communication with the LPUART (with several LPUARTs connected in a network). For instance one of the LPUARTs can be the master, its TX output connected to the RX inputs of the other LPUARTs. The others are slaves, their respective TX outputs are logically ANDed together and connected to the RX input of the master.

In multiprocessor configurations it is often desirable that only the intended message recipient should actively receive the full message contents, thus reducing redundant LPUART service overhead for all non addressed receivers.

The non addressed devices may be placed in mute mode by means of the muting function. In order to use the mute mode feature, the MME bit must be set in the LPUART\_CR1 register.

In mute mode:

- None of the reception status bits can be set.
- All the receive interrupts are inhibited.
- The RWU bit in LPUART\_ISR register is set to 1. RWU can be controlled automatically by hardware or by software, through the MMRQ bit in the LPUART\_RQR register, under certain conditions.

The LPUART can enter or exit from mute mode using one of two methods, depending on the WAKE bit in the LPUART\_CR1 register:

- Idle Line detection if the WAKE bit is reset,
- Address Mark detection if the WAKE bit is set.

##### Idle line detection (WAKE=0)

The LPUART enters mute mode when the MMRQ bit is written to 1 and the RWU is automatically set.

It wakes up when an Idle frame is detected. Then the RWU bit is cleared by hardware but the IDLE bit is not set in the LPUART\_ISR register. An example of mute mode behavior using Idle line detection is given in [Figure 427](#).

Figure 449. Mute mode using Idle line detection

**Note:** If the MMRQ is set while the IDLE character has already elapsed, mute mode will not be entered (RWU is not set).

If the LPUART is activated while the line is IDLE, the idle state is detected after the duration of one IDLE frame (not only after the reception of one character frame).

#### 4-bit/7-bit address mark detection (WAKE=1)

In this mode, bytes are recognized as addresses if their MSB is a '1' otherwise they are considered as data. In an address byte, the address of the targeted receiver is put in the 4 or 7 LSBs. The choice of 7 or 4 bit address detection is done using the ADDM7 bit. This 4-bit/7-bit word is compared by the receiver with its own address which is programmed in the ADD bits in the LPUART\_CR2 register.

**Note:** In 7-bit and 9-bit data modes, address detection is done on 6-bit and 8-bit addresses (ADD[5:0] and ADD[7:0]) respectively.

The LPUART enters mute mode when an address character is received which does not match its programmed address. In this case, the RWU bit is set by hardware. The RXNE flag is not set for this address byte and no interrupt or DMA request is issued when the LPUART enters mute mode.

The LPUART also enters mute mode when the MMRQ bit is written to 1. The RWU bit is also automatically set in this case.

The LPUART exits from mute mode when an address character is received which matches the programmed address. Then the RWU bit is cleared and subsequent bytes are received normally. The RXNE bit is set for the address character since the RWU bit has been cleared.

An example of mute mode behavior using address mark detection is given in [Figure 428](#).

Figure 450. Mute mode using address mark detection

#### 41.4.7 LPUART parity control

Parity control (generation of parity bit in transmission and parity checking in reception) can be enabled by setting the PCE bit in the LPUART\_CR1 register. Depending on the frame length defined by the M bits, the possible LPUART frame formats are as listed in [Table 252](#).

Table 260. Frame formats

| M bits | PCE bit | LPUART frame <sup>(1)</sup> |
|--------|---------|-----------------------------|
| 00     | 0       | SB   8-bit data   STB       |
| 00     | 1       | SB   7-bit data   PB   STB  |
| 01     | 0       | SB   9-bit data   STB       |
| 01     | 1       | SB   8-bit data   PB   STB  |
| 10     | 0       | SB   7-bit data   STB       |
| 10     | 1       | SB   6-bit data   PB   STB  |

1. Legends: SB: start bit, STB: stop bit, PB: parity bit.

2. In the data register, the PB is always taking the MSB position (9th, 8th or 7th, depending on the M bits value).

##### Even parity

The parity bit is calculated to obtain an even number of “1s” inside the frame which is made of the 6, 7 or 8 LSB bits (depending on M bits values) and the parity bit.

As an example, if data=00110101, and 4 bits are set, then the parity bit will be 0 if even parity is selected (PS bit in LPUART\_CR1 = 0).

##### Odd parity

The parity bit is calculated to obtain an odd number of “1s” inside the frame made of the 6, 7 or 8 LSB bits (depending on M bits values) and the parity bit.

As an example, if data=00110101 and 4 bits set, then the parity bit will be 1 if odd parity is selected (PS bit in LPUART\_CR1 = 1).

### Parity checking in reception

If the parity check fails, the PE flag is set in the LPUART\_ISR register and an interrupt is generated if PEIE is set in the LPUART\_CR1 register. The PE flag is cleared by software writing 1 to the PECF in the LPUART\_ICR register.

### Parity generation in transmission

If the PCE bit is set in LPUARTx\_CR1, then the MSB bit of the data written in the data register is transmitted but is changed by the parity bit (even number of “1s” if even parity is selected (PS=0) or an odd number of “1s” if odd parity is selected (PS=1)).

## 41.4.8 Single-wire half-duplex communication using LPUART

Single-wire half-duplex mode is selected by setting the HDSEL bit in the LPUART\_CR3 register. In this mode, the following bits must be kept cleared:

- LINEN and CLKEN bits in the LPUART\_CR2 register,
- SCEN and IREN bits in the LPUART\_CR3 register.

The LPUART can be configured to follow a single-wire half-duplex protocol where the TX and RX lines are internally connected. The selection between half- and Full-duplex communication is made with a control bit HDSEL in LPUART\_CR3.

As soon as HDSEL is written to 1:

- The TX and RX lines are internally connected
- The RX pin is no longer used
- The TX pin is always released when no data is transmitted. Thus, it acts as a standard I/O in idle or in reception. It means that the I/O must be configured so that TX is configured as alternate function open-drain with an external pull-up.

Apart from this, the communication protocol is similar to normal LPUART mode. Any conflicts on the line must be managed by software (by the use of a centralized arbiter, for instance). In particular, the transmission is never blocked by hardware and continues as soon as data is written in the data register while the TE bit is set.

*Note: In LPUART, in the case of 1-stop bit configuration, the RXNE flag is set in the middle of the stop bit.*

## 41.4.9 Continuous communication in DMA mode using LPUART

The LPUART is capable of performing continuous communication using the DMA. The DMA requests for Rx buffer and Tx buffer are generated independently.

*Note: Use the LPUART as explained in [Section 41.4.3](#). To perform continuous communication, you can clear the TXE/ RXNE flags in the LPUART\_ISR register.*

### Transmission using DMA

DMA mode can be enabled for transmission by setting DMAT bit in the LPUART\_CR3 register. Data is loaded from a SRAM area configured using the DMA peripheral (refer to Section *Direct memory access controller (DMA)*) to the LPUART\_TDR register whenever the TXE bit is set. To map a DMA channel for LPUART transmission, use the following procedure (x denotes the channel number):

1. Write the LPUART\_TDR register address in the DMA control register to configure it as the destination of the transfer. The data is moved to this address from memory after each TXE event.
2. Write the memory address in the DMA control register to configure it as the source of the transfer. The data is loaded into the LPUART\_TDR register from this memory area after each TXE event.
3. Configure the total number of bytes to be transferred to the DMA control register.
4. Configure the channel priority in the DMA register
5. Configure DMA interrupt generation after half/ full transfer as required by the application.
6. Clear the TC flag in the LPUART\_ISR register by setting the TCCF bit in the LPUART\_ICR register.
7. Activate the channel in the DMA register.

When the number of data transfers programmed in the DMA Controller is reached, the DMA controller generates an interrupt on the DMA channel interrupt vector.

In transmission mode, once the DMA has written all the data to be transmitted (the TCIF flag is set in the DMA\_ISR register), the TC flag can be monitored to make sure that the LPUART communication is complete. This is required to avoid corrupting the last transmission before disabling the LPUART or entering Stop mode. Software must wait until TC=1. The TC flag remains cleared during all data transfers and it is set by hardware at the end of transmission of the last frame.

Figure 451. Transmission using DMA

### Reception using DMA

DMA mode can be enabled for reception by setting the DMAR bit in LPUART\_CR3 register. Data is loaded from the LPUART\_RDR register to a SRAM area configured using the DMA peripheral (refer Section *Direct memory access controller (DMA)*) whenever a data byte is received. To map a DMA channel for LPUART reception, use the following procedure:

1. Write the LPUART\_RDR register address in the DMA control register to configure it as the source of the transfer. The data is moved from this address to the memory after each RXNE event.
2. Write the memory address in the DMA control register to configure it as the destination of the transfer. The data is loaded from LPUART\_RDR to this memory area after each RXNE event.
3. Configure the total number of bytes to be transferred to the DMA control register.
4. Configure the channel priority in the DMA control register
5. Configure interrupt generation after half/ full transfer as required by the application.
6. Activate the channel in the DMA control register.

When the number of data transfers programmed in the DMA Controller is reached, the DMA controller generates an interrupt on the DMA channel interrupt vector.

Figure 452. Reception using DMA

### Error flagging and interrupt generation in multibuffer communication

In multibuffer communication if any error occurs during the transaction the error flag is asserted after the current byte. An interrupt is generated if the interrupt enable flag is set. For framing error, overrun error and noise flag which are asserted with RXNE in single byte reception, there is a separate error flag interrupt enable bit (EIE bit in the LPUART\_CR3 register), which, if set, enables an interrupt after the current byte if any of these errors occur.

#### 41.4.10 RS232 hardware flow control and RS485 Driver Enable using LPUART

It is possible to control the serial data flow between 2 devices by using the CTS input and the RTS output. The [Figure 441](#) shows how to connect 2 devices in this mode:

Figure 453. Hardware flow control between 2 LPUARTs

RS232 RTS and CTS flow control can be enabled independently by writing the RTSE and CTSE bits respectively to 1 (in the LPUART\_CR3 register).

### RS232 RTS flow control

If the RTS flow control is enabled (RTSE=1), then RTS is deasserted (tied low) as long as the LPUART receiver is ready to receive a new data. When the receive register is full, RTS is asserted, indicating that the transmission is expected to stop at the end of the current frame.

[Figure 442](#) shows an example of communication with RTS flow control enabled.

**Figure 454. RS232 RTS flow control**

### RS232 CTS flow control

If the CTS flow control is enabled (CTSE=1), then the transmitter checks the CTS input before transmitting the next frame. If CTS is deasserted (tied low), then the next data is transmitted (assuming that data is to be transmitted, in other words, if TXE=0), else the transmission does not occur. When CTS is asserted during a transmission, the current transmission is completed before the transmitter stops.

When CTSE=1, the CTSIF status bit is automatically set by hardware as soon as the CTS input toggles. It indicates when the receiver becomes ready or not ready for communication. An interrupt is generated if the CTSIE bit in the LPUART\_CR3 register is set. [Figure 443](#) shows an example of communication with CTS flow control enabled.

Figure 455. RS232 CTS flow control

**Note:** For correct behavior, CTS must be deasserted at least 3 LPUART clock source periods before the end of the current character. In addition it should be noted that the CTSCF flag may not be set for pulses shorter than  $2 \times PCLK$  periods.

### RS485 Driver Enable

The driver enable feature is enabled by setting bit DEM in the LPUART\_CR3 control register. This allows the user to activate the external transceiver control, through the DE (Driver Enable) signal. The assertion time is the time between the activation of the DE signal and the beginning of the START bit. It is programmed using the DEAT [4:0] bit fields in the LPUART\_CR1 control register. The de-assertion time is the time between the end of the last stop bit, in a transmitted message, and the de-activation of the DE signal. It is programmed using the DEDT [4:0] bit fields in the LPUART\_CR1 control register. The polarity of the DE signal can be configured using the DEP bit in the LPUART\_CR3 control register.

In LPUART, the DEAT and DEDT are expressed in USART clock source ( $f_{CK}$ ) cycles:

- The Driver enable assertion time =
  - $(1 + (DEAT \times P)) \times f_{CK}$ , if  $P \neq 0$
  - $(1 + DEAT) \times f_{CK}$ , if  $P = 0$
- The Driver enable de-assertion time =
  - $(1 + (DEDT \times P)) \times f_{CK}$ , if  $P \neq 0$
  - $(1 + DEDT) \times f_{CK}$ , if  $P = 0$

With  $P = BRR[14:11]$

#### 41.4.11 Wake-up from Stop mode using LPUART

The LPUART is able to wake up the MCU from Stop mode when the UESM bit is set and the LPUART clock is set to HSI16 or LSE (refer to the *Reset and clock control (RCC)* section).

- LPUART source clock is HSI
 

If during Stop mode the HSI clock is switched OFF, when a falling edge on the LPUART receive line is detected, the LPUART interface requests the HSI clock to be switched ON. The HSI clock is then used for the frame reception.

  - If the wake-up event is verified, the MCU wakes up from low-power mode and data reception goes on normally.
  - If the wake-up event is not verified, the HSI clock is switched OFF again, the MCU is not waken up and stays in low-power mode and the clock request is released.

*Note: If the LPUART kernel clock is kept ON during Stop mode, there is no constraint on the maximum baud rate that allows waking up from Stop mode. It is the same as in Run mode.*

- LPUART source clock is LSE
 

Same principle as described in case LPUART source clock is HSI with the difference that the LSE is ON in Stop mode, but the LSE clock is not propagated to LPUART if the LPUART is not requesting it. The LSE clock is not OFF but there is a clock gating to avoid useless consumption.

When the LPUART clock source is configured to be  $f_{LSE}$  or  $f_{HSI}$ , it is possible to keep enabled this clock during Stop mode by setting the UCESM bit in LPUART\_CR3 control register.

*Note: When LPUART is used to wake up from stop with LSE is selected as LPUART clock source, and desired baud rate is 9600 baud, the bit UCESM bit in LPUART\_CR3 control register must be set.*

The MCU wake-up from Stop mode can be done using the standard RXNE interrupt. In this case, the RXNEIE bit must be set before entering Stop mode.

Alternatively, a specific interrupt may be selected through the WUS bit fields.

In order to be able to wake up the MCU from Stop mode, the UESM bit in the LPUART\_CR1 control register must be set prior to entering Stop mode.

When the wake-up event is detected, the WUF flag is set by hardware and a wake-up interrupt is generated if the WUFIE bit is set.

*Note: Before entering Stop mode, the user must ensure that the LPUART is not performing a transfer. BUSY flag cannot ensure that Stop mode is never entered during a running reception.*

*The WUF flag is set when a wake-up event is detected, independently of whether the MCU is in Stop or in an active mode.*

*When entering Stop mode just after having initialized and enabled the receiver, the REACK bit must be checked to ensure the LPUART is actually enabled.*

*When DMA is used for reception, it must be disabled before entering Stop mode and re-enabled upon exit from Stop mode.*

*The wake-up from Stop mode feature is not available for all modes. For example it doesn't work in SPI mode because the SPI operates in master mode only.*

### Using mute mode with Stop mode

If the LPUART is put into mute mode before entering Stop mode:

- Wake-up from mute mode on idle detection must not be used, because idle detection cannot work in Stop mode.
- If the wake-up from mute mode on address match is used, then the source of wake-up from Stop mode must also be the address match. If the RXNE flag is set when entering the Stop mode, the interface will remain in mute mode upon address match and wake up from Stop.
- If the LPUART is configured to wake up the MCU from Stop mode on START bit detection, the WUF flag is set, but the RXNE flag is not set.

### Determining the maximum LPUART baud rate allowing to wake up correctly from Stop mode when the LPUART clock source is the HSI clock

The maximum baud rate allowing to wake up correctly from Stop mode depends on:

- the parameter  $t_{WULPUART}$  (wake-up time from Stop mode) provided in the device datasheet
- the LPUART receiver tolerance provided in the [Section 41.4.5: Tolerance of the LPUART receiver to clock deviation](#).

Let us take this example: M bits = 01, 2 stop bits,  $BRR \geq 4096$ .

In these conditions, according to [Table 259: Tolerance of the LPUART receiver](#), the LPUART receiver tolerance is 4.42 %.

$DTRA + DQUANT + DREC + DTCL + DWU < \text{LPUART receiver tolerance}$

$DWU_{\max} = t_{WULPUART} / (11 \times T_{\text{bit Min}})$

$T_{\text{bit Min}} = t_{WULPUART} / (11 \times DWU_{\max})$

If we consider an ideal case where the parameters DTRA, DQUANT, DREC and DTCL are at 0%, the DWU max is 4.42 %. In reality, we need to consider at least the HSI inaccuracy.

Let us consider the HSI inaccuracy = 1 %,  $t_{WULPUART} = 1.7 \mu\text{s}$  (in case of Stop mode with main regulator in Run mode, Range 1 ):

$DWU_{\max} = 4.42 \% - 1 \% = 3.42 \%$

$T_{\text{bit min}} = 1.7 \mu\text{s} / (11 \times 3.42 \%) = 4.5 \mu\text{s}$ .

In these conditions, the maximum baud rate allowing to wake up correctly from Stop mode is  $1 / 4.5 \mu\text{s} = 220 \text{ kbaud}$ .

## 41.5 LPUART in low-power mode

**Table 261. Effect of low-power modes on the LPUART**

| Mode            | Description                                                                |
|-----------------|----------------------------------------------------------------------------|
| Sleep           | No effect.                                                                 |
| Low-power run   | No effect.                                                                 |
| Low-power sleep | No effect. USART interrupt causes the device to exit Low-power sleep mode. |

Table 261. Effect of low-power modes on the LPUART (continued)

| Mode                      | Description                                                                                                                                                                                                                                                                                                |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Stop 0, Stop 1 and Stop 2 | The LPUART registers content is kept. The LPUART is able to wake up the MCU from Stop 0, Stop 1 and Stop 2 modes when the UESM bit is set and the LPUART clock is set to HSI16 or LSE.<br>The MCU wake-up from Stop 0, Stop 1 and 2 modes can be done using either the standard RXNE or the WUF interrupt. |
| Standby                   | The LPUART is powered down and must be reinitialized when the device has exited from Standby or Shutdown mode.                                                                                                                                                                                             |
| Shutdown                  |                                                                                                                                                                                                                                                                                                            |

## 41.6 LPUART interrupts

Table 262. LPUART interrupt requests

| Interrupt event                                                           | Event flag         | Enable Control bit |
|---------------------------------------------------------------------------|--------------------|--------------------|
| Transmit data register empty                                              | TXE                | TXEIE              |
| CTS interrupt                                                             | CTSIF              | CTSIE              |
| Transmission Complete                                                     | TC                 | TCIE               |
| Receive data register not empty (data ready to be read)                   | RXNE               | RXNEIE             |
| Overrun error detected                                                    | ORE                |                    |
| Idle line detected                                                        | IDLE               | IDLEIE             |
| Parity error                                                              | PE                 | PEIE               |
| Noise Flag, Overrun error and Framing Error in multibuffer communication. | NF or ORE or FE    | EIE                |
| Character match                                                           | CMF                | CMIE               |
| Wake-up from Stop mode                                                    | WUF <sup>(1)</sup> | WUFIE              |

1. The WUF interrupt is active only in Stop mode.

The LPUART interrupt events are connected to the same interrupt vector (see [Figure 444](#)).

- During transmission: Transmission Complete, Clear to Send, Transmit data Register empty or Framing error interrupt.
- During reception: Idle Line detection, Overrun error, Receive data register not empty, Parity error, Noise Flag, Framing Error, Character match, etc.

These events generate an interrupt if the corresponding Enable Control Bit is set.

Figure 456. LPUART interrupt mapping diagram

## 41.7 LPUART registers

Refer to [Section 1.2 on page 69](#) for a list of abbreviations used in register descriptions.

The peripheral registers have to be accessed by words (32 bits).

Bits 31:29 Reserved, must be kept at reset value

Bit 28 **M1**: Word length

This bit, with bit 12 (M0) determines the word length. It is set or cleared by software.

M[1:0] = 00: 1 Start bit, 8 data bits, n stop bits

M[1:0] = 01: 1 Start bit, 9 data bits, n stop bits

M[1:0] = 10: 1 Start bit, 7 data bits, n stop bits

This bit can only be written when the LPUART is disabled (UE=0).

Bit 27 Reserved, must be kept at reset value

Bit 26 Reserved, must be kept at reset value

Bits 25:21 **DEAT[4:0]**: Driver Enable assertion time

This 5-bit value defines the time between the activation of the DE (Driver Enable) signal and the beginning of the start bit. It is expressed in UCLK (USART clock) clock cycles. For more details, refer to RS485 Driver Enable paragraph.

This bit field can only be written when the LPUART is disabled (UE=0).

Bits 20:16 **DEDT[4:0]**: Driver Enable de-assertion time

This 5-bit value defines the time between the end of the last stop bit, in a transmitted message, and the de-activation of the DE (Driver Enable) signal. It is expressed in UCLK (USART clock) clock cycles. For more details, refer to RS485 Driver Enable paragraph.

If the LPUART\_TDR register is written during the DEDT time, the new data is transmitted only when the DEDT and DEAT times have both elapsed.

This bit field can only be written when the LPUART is disabled (UE=0).

Bit 15 Reserved, must be kept at reset value

Bit 14 **CMIE**: Character match interrupt enable

This bit is set and cleared by software.

0: Interrupt is inhibited

1: A LPUART interrupt is generated when the CMF bit is set in the LPUART\_ISR register.

**Bit 13 MME:** Mute mode enable

This bit activates the mute mode function of the LPUART. When set, the LPUART can switch between the active and mute modes, as defined by the WAKE bit. It is set and cleared by software.

0: Receiver in active mode permanently

1: Receiver can switch between mute mode and active mode.

**Bit 12 M0:** Word length

This bit, with bit 28 (M1) determines the word length. It is set or cleared by software. See Bit 28 (M1) description.

This bit can only be written when the LPUART is disabled (UE=0).

**Bit 11 WAKE:** Receiver wake-up method

This bit determines the LPUART wake-up method from mute mode. It is set or cleared by software.

0: Idle line

1: Address mark

This bit field can only be written when the LPUART is disabled (UE=0).

**Bit 10 PCE:** Parity control enable

This bit selects the hardware parity control (generation and detection). When the parity control is enabled, the computed parity is inserted at the MSB position (9th bit if M=1; 8th bit if M=0) and parity is checked on the received data. This bit is set and cleared by software. Once it is set, PCE is active after the current byte (in reception and in transmission).

0: Parity control disabled

1: Parity control enabled

This bit field can only be written when the LPUART is disabled (UE=0).

**Bit 9 PS:** Parity selection

This bit selects the odd or even parity when the parity generation/detection is enabled (PCE bit set). It is set and cleared by software. The parity will be selected after the current byte.

0: Even parity

1: Odd parity

This bit field can only be written when the LPUART is disabled (UE=0).

**Bit 8 PEIE:** PE interrupt enable

This bit is set and cleared by software.

0: Interrupt is inhibited

1: An LPUART interrupt is generated whenever PE=1 in the LPUART\_ISR register

**Bit 7 TXEIE:** interrupt enable

This bit is set and cleared by software.

0: Interrupt is inhibited

1: An LPUART interrupt is generated whenever TXE=1 in the LPUART\_ISR register

**Bit 6 TCIE:** Transmission complete interrupt enable

This bit is set and cleared by software.

0: Interrupt is inhibited

1: An LPUART interrupt is generated whenever TC=1 in the LPUART\_ISR register

**Bit 5 RXNEIE:** RXNE interrupt enable

This bit is set and cleared by software.

0: Interrupt is inhibited

1: An LPUART interrupt is generated whenever ORE=1 or RXNE=1 in the LPUART\_ISR register

Bit 4 **IDLEIE**: IDLE interrupt enable

This bit is set and cleared by software.

0: Interrupt is inhibited

1: An LPUART interrupt is generated whenever IDLE=1 in the LPUART\_ISR register

Bit 3 **TE**: Transmitter enable

This bit enables the transmitter. It is set and cleared by software.

0: Transmitter is disabled

1: Transmitter is enabled

*Note: During transmission, a “0” pulse on the TE bit (“0” followed by “1”) sends a preamble (idle line) after the current word. In order to generate an idle character, the TE must not be immediately written to 1. In order to ensure the required duration, the software can poll the TEACK bit in the LPUART\_ISR register.*

*When TE is set there is a 1 bit-time delay before the transmission starts.*

Bit 2 **RE**: Receiver enable

This bit enables the receiver. It is set and cleared by software.

0: Receiver is disabled

1: Receiver is enabled and begins searching for a start bit

Bit 1 **UESM**: LPUART enable in Stop mode

When this bit is cleared, the LPUART is not able to wake up the MCU from Stop mode.

When this bit is set, the LPUART is able to wake up the MCU from Stop mode, provided that the LPUART clock selection is HSI or LSE in the RCC.

This bit is set and cleared by software.

0: LPUART not able to wake up the MCU from Stop mode.

1: LPUART able to wake up the MCU from Stop mode. When this function is active, the clock source for the LPUART must be HSI or LSE (see Section Reset and clock control (RCC)).

*Note: It is recommended to set the UESM bit just before entering Stop mode and clear it on exit from Stop mode.*

Bit 0 **UE**: LPUART enable

When this bit is cleared, the LPUART prescalers and outputs are stopped immediately, and current operations are discarded. The configuration of the LPUART is kept, but all the status flags, in the LPUART\_ISR are reset. This bit is set and cleared by software.

0: LPUART prescaler and outputs disabled, low-power mode

1: LPUART enabled

*Note: In order to go into low-power mode without generating errors on the line, the TE bit must be reset before and the software must wait for the TC bit in the LPUART\_ISR to be set before resetting the UE bit.*

*The DMA requests are also reset when UE = 0 so the DMA channel must be disabled before resetting the UE bit.*

## 41.7.2 Control register 2 (LPUART\_CR2)

Address offset: 0x04

Reset value: 0x0000

Bits 31:28 **ADD[7:4]**: Address of the LPUART node

This bit-field gives the address of the LPUART node or a character code to be recognized.

This is used in multiprocessor communication during mute mode or Stop mode, for wake-up with 7-bit address mark detection. The MSB of the character sent by the transmitter should be equal to 1. It may also be used for character detection during normal reception, mute mode inactive (for example, end of block detection in Modbus protocol). In this case, the whole received character (8-bit) is compared to the ADD[7:0] value and CMF flag is set on match.

This bit field can only be written when reception is disabled (RE = 0) or the LPUART is disabled (UE=0)

Bits 27:24 **ADD[3:0]**: Address of the LPUART node

This bit-field gives the address of the LPUART node or a character code to be recognized.

This is used in multiprocessor communication during mute mode or Stop mode, for wake-up with address mark detection.

This bit field can only be written when reception is disabled (RE = 0) or the LPUART is disabled (UE=0)

Bits 23:20 Reserved, must be kept at reset value

Bit 19 **MSBFIRST**: Most significant bit first

This bit is set and cleared by software.

0: data is transmitted/received with data bit 0 first, following the start bit.

1: data is transmitted/received with the MSB (bit 7/8/9) first, following the start bit.

This bit field can only be written when the LPUART is disabled (UE=0).

Bit 18 **DATAINV**: Binary data inversion

This bit is set and cleared by software.

0: Logical data from the data register are send/received in positive/direct logic. (1=H, 0=L)

1: Logical data from the data register are send/received in negative/inverse logic. (1=L, 0=H). The parity bit is also inverted.

This bit field can only be written when the LPUART is disabled (UE=0).

Bit 17 **TXINV**: TX pin active level inversion

This bit is set and cleared by software.

0: TX pin signal works using the standard logic levels ( $V_{DD}$  = 1/idle, Gnd=0/mark)

1: TX pin signal values are inverted. ( $V_{DD}$  = 0/mark, Gnd=1/idle).

This allows the use of an external inverter on the TX line.

This bit field can only be written when the LPUART is disabled (UE=0).

**Bit 16 RXINV:** RX pin active level inversion

This bit is set and cleared by software.

0: RX pin signal works using the standard logic levels ( $V_{DD}$  =1/idle, Gnd=0/mark)

1: RX pin signal values are inverted. ( $V_{DD}$  =0/mark, Gnd=1/idle).

This allows the use of an external inverter on the RX line.

This bit field can only be written when the LPUART is disabled (UE=0).

**Bit 15 SWAP:** Swap TX/RX pins

This bit is set and cleared by software.

0: TX/RX pins are used as defined in standard pinout

1: The TX and RX pins functions are swapped. This allows to work in the case of a cross-wired connection to another UART.

This bit field can only be written when the LPUART is disabled (UE=0).

**Bit 14** Reserved, must be kept at reset value**Bits 13:12 STOP[1:0]:** STOP bits

These bits are used for programming the stop bits.

00: 1 stop bit

01: Reserved.

10: 2 stop bits

11: Reserved

This bit field can only be written when the LPUART is disabled (UE=0).

**Bits 11:5** Reserved, must be kept at reset value**Bit 4 ADDM7:** 7-bit Address Detection/4-bit Address Detection

This bit is for selection between 4-bit address detection or 7-bit address detection.

0: 4-bit address detection

1: 7-bit address detection (in 8-bit data mode)

This bit can only be written when the LPUART is disabled (UE=0)

*Note: In 7-bit and 9-bit data modes, the address detection is done on 6-bit and 8-bit address (ADD[5:0] and ADD[7:0]) respectively.*

**Bits 3:0** Reserved, must be kept at reset value.

### 41.7.3 Control register 3 (LPUART\_CR3)

Address offset: 0x08

Reset value: 0x0000

| 31   | 30   | 29   | 28      | 27   | 26    | 25   | 24   | 23    | 22    | 21       | 20   | 19     | 18   | 17   | 16   |

| rw   | rw   | rw   | rw      |      | rw    | rw   | rw   | rw    | rw    |          |      | rw     |      |      | rw   |

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **UCESM**: LPUART Clock Enable in Stop mode.

This bit is set and cleared by software.

0: LPUART Clock is disabled in Stop mode.

1: LPUART Clock is enabled in Stop mode.

*Note: In order to be able to wake up the MCU from Stop mode with LPUART at 9600 baud, the UCESM bit must be set prior to entering the Stop mode.*

Bit 22 **WUFIE**: Wake-up from Stop mode interrupt enable

This bit is set and cleared by software.

0: Interrupt is inhibited

1: An LPUART interrupt is generated whenever WUF=1 in the LPUART\_ISR register

*Note: WUFIE must be set before entering in Stop mode.*

*The WUF interrupt is active only in Stop mode.*

*If the LPUART does not support the wake-up from Stop feature, this bit is reserved and must be kept at reset value.*

Bits 21:20 **WUS[1:0]**: Wake-up from Stop mode interrupt flag selection

This bit-field specify the event which activates the WUF (wake-up from Stop mode flag).

00: WUF active on address match (as defined by ADD[7:0] and ADDM7)

01: Reserved.

10: WUF active on Start bit detection

11: WUF active on RXNE.

This bit field can only be written when the LPUART is disabled (UE=0).

*Note: If the LPUART does not support the wake-up from Stop feature, this bit is reserved and must be kept at reset value.*

Bits 19:16 Reserved, must be kept at reset value.

Bit 15 **DEP**: Driver enable polarity selection

0: DE signal is active high.

1: DE signal is active low.

This bit can only be written when the LPUART is disabled (UE=0).

Bit 14 **DEM**: Driver enable mode

This bit allows the user to activate the external transceiver control, through the DE signal.

0: DE function is disabled.

1: DE function is enabled. The DE signal is output on the RTS pin.

This bit can only be written when the LPUART is disabled (UE=0).

**Bit 13 DDRE:** DMA Disable on Reception Error

0: DMA is not disabled in case of reception error. The corresponding error flag is set but RXNE is kept 0 preventing from overrun. As a consequence, the DMA request is not asserted, so the erroneous data is not transferred (no DMA request), but next correct received data will be transferred.

1: DMA is disabled following a reception error. The corresponding error flag is set, as well as RXNE. The DMA request is masked until the error flag is cleared. This means that the software must first disable the DMA request (DMAR = 0) or clear RXNE before clearing the error flag.

This bit can only be written when the LPUART is disabled (UE=0).

*Note: The reception errors are: parity error, framing error or noise error.*

**Bit 12 OVRDIS:** Overrun Disable

This bit is used to disable the receive overrun detection.

0: Overrun Error Flag, ORE, is set when received data is not read before receiving new data.

1: Overrun functionality is disabled. If new data is received while the RXNE flag is still set the ORE flag is not set and the new received data overwrites the previous content of the LPUART\_RDR register.

This bit can only be written when the LPUART is disabled (UE=0).

*Note: This control bit allows checking the communication flow without reading the data.*

**Bit 11** Reserved, must be kept at reset value.**Bit 10 CTSIE:** CTS interrupt enable

0: Interrupt is inhibited

1: An interrupt is generated whenever CTSIF=1 in the LPUART\_ISR register

**Bit 9 CTSE:** CTS enable

0: CTS hardware flow control disabled

1: CTS mode enabled, data is only transmitted when the CTS input is deasserted (tied to 0). If the CTS input is asserted while data is being transmitted, then the transmission is completed before stopping. If data is written into the data register while CTS is asserted, the transmission is postponed until CTS is deasserted.

This bit can only be written when the LPUART is disabled (UE=0)

**Bit 8 RTSE:** RTS enable

0: RTS hardware flow control disabled

1: RTS output enabled, data is only requested when there is space in the receive buffer. The transmission of data is expected to cease after the current character has been transmitted. The RTS output is deasserted (pulled to 0) when data can be received.

This bit can only be written when the LPUART is disabled (UE=0).

**Bit 7 DMAT:** DMA enable transmitter

This bit is set/reset by software

1: DMA mode is enabled for transmission

0: DMA mode is disabled for transmission

**Bit 6 DMAR:** DMA enable receiver

This bit is set/reset by software

1: DMA mode is enabled for reception

0: DMA mode is disabled for reception

**Bits 5:4** Reserved, must be kept at reset value.

Bit 3 **HDSEL**: Half-duplex selection

Selection of single-wire half-duplex mode

0: Half duplex mode is not selected

1: Half duplex mode is selected

This bit can only be written when the LPUART is disabled (UE=0).

Bits 2:1 Reserved, must be kept at reset value.

Bit 0 **EIE**: Error interrupt enable

Error Interrupt Enable Bit is required to enable interrupt generation in case of a framing error, overrun error or noise flag (FE=1 or ORE=1 or NF=1 in the LPUART\_ISR register).

0: Interrupt is inhibited

1: An interrupt is generated when FE=1 or ORE=1 or NF=1 in the LPUART\_ISR register.

#### 41.7.4 Baud rate register (LPUART\_BRR)

This register can only be written when the LPUART is disabled (UE=0).

Address offset: 0x0C

Reset value: 0x0000

|           |      |      |      |      |      |      |      |      |      |      |      |            |    |    |    |

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **BRR[19:0]**

**Note:** *It is forbidden to write values less than 0x300 in the LPUART\_BRR register.  
Provided that LPUARTx\_BRR must be  $\geq 0x300$  and LPUART\_BRR is 20-bit, a care should be taken when generating high baud rates using high fck values. fck must be in the range  $[3 \times \text{baud rate}, .4096 \times \text{baud rate}]$ .*

#### 41.7.5 Request register (LPUART\_RQR)

Address offset: 0x18

Reset value: 0x0000

|      |      |      |      |      |      |      |      |      |      |      |      |       |      |       |      |
|------|------|------|------|------|------|------|------|------|------|------|------|-------|------|-------|------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19    | 18   | 17    | 16   |

| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3     | 2    | 1     | 0    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | RXFRQ | MMRQ | SBKRQ | Res. |
|      |      |      |      |      |      |      |      |      |      |      |      | w     | w    | w     |      |

Bits 31:4 Reserved, must be kept at reset value

Bit 3 **RXFRQ**: Receive data flush request

Writing 1 to this bit clears the RXNE flag.

This allows to discard the received data without reading it, and avoid an overrun condition.

Bit 2 **MMRQ**: Mute mode request

Writing 1 to this bit puts the LPUART in mute mode and resets the RWU flag.

Bit 1 **SBKRQ**: Send break request

Writing 1 to this bit sets the SBKF flag and request to send a BREAK on the line, as soon as the transmit machine is available.

*Note: In the case the application needs to send the break character following all previously inserted data, including the ones not yet transmitted, the software should wait for the TXE flag assertion before setting the SBKRQ bit.*

Bit 0 Reserved, must be kept at reset value

### 41.7.6 Interrupt & status register (LPUART\_ISR)

Address offset: 0x1C

Reset value: 0x00C0

| 31   | 30   | 29   | 28   | 27   | 26   | 25    | 24   | 23   | 22     | 21     | 20   | 19  | 18   | 17  | 16   |

|      |      |      |      |      | r    | r     |      | r    | r      | r      | r    | r   | r    | r   | r    |

Bits 31:23 Reserved, must be kept at reset value.

Bit 22 **REACK**: Receive enable acknowledge flag

This bit is set/reset by hardware, when the Receive Enable value is taken into account by the LPUART.

It can be used to verify that the LPUART is ready for reception before entering Stop mode.

*Note: If the LPUART does not support the wake-up from Stop feature, this bit is reserved and kept at reset value.*

Bit 21 **TEACK**: Transmit enable acknowledge flag

This bit is set/reset by hardware, when the Transmit Enable value is taken into account by the LPUART.

It can be used when an idle frame request is generated by writing TE=0, followed by TE=1 in the LPUART\_CR1 register, in order to respect the TE=0 minimum period.

Bit 20 **WUF**: Wake-up from Stop mode flag

This bit is set by hardware, when a wake-up event is detected. The event is defined by the WUS bit field. It is cleared by software, writing a 1 to the WUCF in the LPUART\_ICR register. An interrupt is generated if WUFIE=1 in the LPUART\_CR3 register.

*Note: When UESM is cleared, WUF flag is also cleared.*

*The WUF interrupt is active only in Stop mode.*

*If the LPUART does not support the wake-up from Stop feature, this bit is reserved and kept at reset value.*

- Bit 19 **RWU**: Receiver wake-up from mute mode  
This bit indicates if the LPUART is in mute mode. It is cleared/set by hardware when a wake-up/mute sequence is recognized. The mute mode control sequence (address or IDLE) is selected by the WAKE bit in the LPUART\_CR1 register.  
When wake-up on Idle mode is selected, this bit can only be set by software, writing 1 to the MMRQ bit in the LPUART\_RQR register.  
0: Receiver in active mode  
1: Receiver in mute mode
- Bit 18 **SBKF**: Send break flag  
This bit indicates that a send break character was requested. It is set by software, by writing 1 to the SBKRQ bit in the LPUART\_CR3 register. It is automatically reset by hardware during the stop bit of break transmission.  
0: No break character is transmitted  
1: Break character will be transmitted
- Bit 17 **CMF**: Character match flag  
This bit is set by hardware, when the character defined by ADD[7:0] is received. It is cleared by software, writing 1 to the CMCF in the LPUART\_ICR register.  
An interrupt is generated if CMIE=1 in the LPUART\_CR1 register.  
0: No Character match detected  
1: Character Match detected
- Bit 16 **BUSY**: Busy flag  
This bit is set and reset by hardware. It is active when a communication is ongoing on the RX line (successful start bit detected). It is reset at the end of the reception (successful or not).  
0: LPUART is idle (no reception)  
1: Reception on going
- Bits 15:11 Reserved, must be kept at reset value.
- Bit 10 **CTS**: CTS flag  
This bit is set/reset by hardware. It is an inverted copy of the status of the CTS input pin.  
0: CTS line set  
1: CTS line reset  
*Note: If the hardware flow control feature is not supported, this bit is reserved and kept at reset value.*
- Bit 9 **CTSIF**: CTS interrupt flag  
This bit is set by hardware when the CTS input toggles, if the CTSE bit is set. It is cleared by software, by writing 1 to the CTSCF bit in the LPUART\_ICR register.  
An interrupt is generated if CTSIE=1 in the LPUART\_CR3 register.  
0: No change occurred on the CTS status line  
1: A change occurred on the CTS status line  
*Note: If the hardware flow control feature is not supported, this bit is reserved and kept at reset value.*
- Bit 8 Reserved, must be kept at reset value.

**Bit 7 TXE:** Transmit data register empty

This bit is set by hardware when the content of the LPUART\_TDR register has been transferred into the shift register. It is cleared by a write to the LPUART\_TDR register.

An interrupt is generated if the TXEIE bit =1 in the LPUART\_CR1 register.

0: data is not transferred to the shift register

1: data is transferred to the shift register)

*Note: This bit is used during single buffer transmission.*

**Bit 6 TC:** Transmission complete

This bit is set by hardware if the transmission of a frame containing data is complete and if TXE is set. An interrupt is generated if TCIE=1 in the LPUART\_CR1 register. It is cleared by software, writing 1 to the TCCF in the LPUART\_ICR register or by a write to the LPUART\_TDR register.

An interrupt is generated if TCIE=1 in the LPUART\_CR1 register.

0: Transmission is not complete

1: Transmission is complete

*Note: If TE bit is reset and no transmission is on going, the TC bit will be set immediately.*

**Bit 5 RXNE:** Read data register not empty

This bit is set by hardware when the content of the RDR shift register has been transferred to the LPUART\_RDR register. It is cleared by a read to the LPUART\_RDR register. The RXNE flag can also be cleared by writing 1 to the RXFRQ in the LPUART\_RQR register.

An interrupt is generated if RXNEIE=1 in the LPUART\_CR1 register.

0: data is not received

1: Received data is ready to be read.

**Bit 4 IDLE:** Idle line detected

This bit is set by hardware when an Idle Line is detected. An interrupt is generated if IDLEIE=1 in the LPUART\_CR1 register. It is cleared by software, writing 1 to the IDLECF in the LPUART\_ICR register.

0: No Idle line is detected

1: Idle line is detected

*Note: The IDLE bit will not be set again until the RXNE bit has been set (i.e. a new idle line occurs).*

*If mute mode is enabled (MME=1), IDLE is set if the LPUART is not mute (RWU=0), whatever the mute mode selected by the WAKE bit. If RWU=1, IDLE is not set.*

**Bit 3 ORE:** Overrun error

This bit is set by hardware when the data currently being received in the shift register is ready to be transferred into the RDR register while RXNE=1. It is cleared by a software, writing 1 to the ORECF, in the LPUART\_ICR register.

An interrupt is generated if RXNEIE=1 in the LPUART\_CR1 register, or EIE = 1 in the LPUART\_CR3 register.

0: No overrun error

1: Overrun error is detected

*Note: When this bit is set, the RDR register content is not lost but the shift register is overwritten. An interrupt is generated if the ORE flag is set during multibuffer communication if the EIE bit is set.*

*This bit is permanently forced to 0 (no overrun detection) when the OVRDIS bit is set in the LPUART\_CR3 register.*

**Bit 2 NF:** START bit Noise detection flag

This bit is set by hardware when noise is detected on the START bit of a received frame. It is cleared by software, writing 1 to the NFCF bit in the LPUART\_ICR register.

0: No noise is detected

1: Noise is detected

*Note: This bit does not generate an interrupt as it appears at the same time as the RXNE bit which itself generates an interrupt. An interrupt is generated when the NF flag is set during multibuffer communication if the EIE bit is set.*

**Bit 1 FE:** Framing error

This bit is set by hardware when a de-synchronization, excessive noise or a break character is detected. It is cleared by software, writing 1 to the FECF bit in the LPUART\_ICR register.

An interrupt is generated if EIE = 1 in the LPUART\_CR3 register.

0: No Framing error is detected

1: Framing error or break character is detected

**Bit 0 PE:** Parity error

This bit is set by hardware when a parity error occurs in receiver mode. It is cleared by software, writing 1 to the PECF in the LPUART\_ICR register.

An interrupt is generated if PEIE = 1 in the LPUART\_CR1 register.

0: No parity error

1: Parity error

**41.7.7 Interrupt flag clear register (LPUART\_ICR)**

Address offset: 0x20

Reset value: 0x0000

|      |      |      |      |      |      |       |      |      |      |      |        |       |      |      |      |

Bits 31:21 Reserved, must be kept at reset value.

**Bit 20 WUCF:** Wake-up from Stop mode clear flag

Writing 1 to this bit clears the WUF flag in the LPUART\_ISR register.

*Note: If the LPUART does not support the wake-up from Stop feature, this bit is reserved and kept at reset value.*

Bits 19:18 Reserved, must be kept at reset value.

**Bit 17 CMCF:** Character match clear flag

Writing 1 to this bit clears the CMF flag in the LPUART\_ISR register.

Bits 16:10 Reserved, must be kept at reset value.

**Bit 9 CTSCF:** CTS clear flag

Writing 1 to this bit clears the CTSIF flag in the LPUART\_ISR register.

Bits 8:7 Reserved, must be kept at reset value.

Bit 6 **TCCF**: Transmission complete clear flag

Writing 1 to this bit clears the TC flag in the LPUART\_ISR register.

Bit 5 Reserved, must be kept at reset value.

Bit 4 **IDLECF**: Idle line detected clear flag

Writing 1 to this bit clears the IDLE flag in the LPUART\_ISR register.

Bit 3 **ORECF**: Overrun error clear flag

Writing 1 to this bit clears the ORE flag in the LPUART\_ISR register.

Bit 2 **NCF**: Noise detected clear flag

Writing 1 to this bit clears the NF flag in the LPUART\_ISR register.

Bit 1 **FE CF**: Framing error clear flag

Writing 1 to this bit clears the FE flag in the LPUART\_ISR register.

Bit 0 **PECF**: Parity error clear flag

Writing 1 to this bit clears the PE flag in the LPUART\_ISR register.

### 41.7.8 Receive data register (LPUART\_RDR)

Address offset: 0x24

Reset value: Undefined

|      |      |      |      |      |      |      |          |      |      |      |      |      |      |      |      |
|------|------|------|------|------|------|------|----------|------|------|------|------|------|------|------|------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24       | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.     | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. |
|      |      |      |      |      |      |      |          |      |      |      |      |      |      |      |      |

|      |      |      |      |      |      |      | r        | r    | r    | r    | r    | r    | r    | r    | r    |

Bits 31:9 Reserved, must be kept at reset value.

Bits 8:0 **RDR[8:0]**: Receive data value

Contains the received data character.

The RDR register provides the parallel interface between the input shift register and the internal bus (see [Figure 420](#)).

When receiving with the parity enabled, the value read in the MSB bit is the received parity bit.

### 41.7.9 Transmit data register (LPUART\_TDR)

Address offset: 0x28

Reset value: Undefined

|      |      |      |      |      |      |      |          |      |      |      |      |      |      |      |      |
|------|------|------|------|------|------|------|----------|------|------|------|------|------|------|------|------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24       | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.     | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. |
|      |      |      |      |      |      |      |          |      |      |      |      |      |      |      |      |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8        | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | TDR[8:0] |      |      |      |      |      |      |      |      |
|      |      |      |      |      |      |      | rw       | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   |

Bits 31:9 Reserved, must be kept at reset value.

Bits 8:0 **TDR[8:0]**: Transmit data value

Contains the data character to be transmitted.

The TDR register provides the parallel interface between the internal bus and the output shift register (see [Figure 420](#)).

When transmitting with the parity enabled (PCE bit set to 1 in the LPUART\_CR1 register), the value written in the MSB (bit 7 or bit 8 depending on the data length) has no effect because it is replaced by the parity.

*Note: This register must be written only when TXE=1.*

### 41.7.10 LPUART register map

The table below gives the **LPUART** register map and reset values.

**Table 263. LPUART register map and reset values**

| Offset | Register name<br>reset value | 31   |  | 30   |  | 29   |  | 28 |  | 27   |  | 26   |  | 25    |  | 24    |  | 23    |  | 22    |  | 21    |  | 20    |  | 19    |  | 18    |  | 17    |  | 16    |  | 15   |  | 14   |  | 13  |  | 12 |  | 11   |  | 10  |  | 9  |  | 8    |  | 7     |  | 6    |  | 5      |  | 4      |  | 3  |  | 2  |  | 1    |  | 0  |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |   |  |

Refer to [Section 2.2 on page 75](#) for the register boundary addresses.

## 42 Serial peripheral interface (SPI)

### 42.1 Introduction

The SPI interface can be used to communicate with external devices using the SPI protocol. SPI mode is selectable by software. SPI Motorola mode is selected by default after a device reset.

The serial peripheral interface (SPI) protocol supports half-duplex, full-duplex and simplex synchronous, serial communication with external devices. The interface can be configured as master and in this case it provides the communication clock (SCK) to the external slave device. The interface is also capable of operating in multimaster configuration.

### 42.2 SPI main features

- Master or slave operation
- Full-duplex synchronous transfers on three lines
- Half-duplex synchronous transfer on two lines (with bidirectional data line)
- Simplex synchronous transfers on two lines (with unidirectional data line)
- 4 to 16-bit data size selection
- Multimaster mode capability
- 8 master mode baud rate prescalers up to  $f_{PCLK}/2$
- Slave mode frequency up to  $f_{PCLK}/2$ .
- NSS management by hardware or software for both master and slave: dynamic change of master/slave operations
- Programmable clock polarity and phase
- Programmable data order with MSB-first or LSB-first shifting
- Dedicated transmission and reception flags with interrupt capability
- SPI bus busy status flag
- SPI Motorola support
- Hardware CRC feature for reliable communication:
  - CRC value can be transmitted as last byte in Tx mode
  - Automatic CRC error checking for last received byte
- Master mode fault, overrun flags with interrupt capability
- CRC Error flag
- Two 32-bit embedded Rx and Tx FIFOs with DMA capability
- Enhanced TI and NSS pulse modes support

## 42.3 SPI implementation

The following table describes all the SPI instances and their features embedded in the devices.

**Table 264. STM32L47x/L48x/L49x/L4Ax SPI implementation**

| SPI Features                            | SPI1              | SPI2              | SPI3              |

## 42.4 SPI functional description

### 42.4.1 General description

The SPI allows synchronous, serial communication between the MCU and external devices. Application software can manage the communication by polling the status flag or using dedicated SPI interrupt. The main elements of SPI and their interactions are shown in the following block diagram [Figure 457](#).

**Figure 457. SPI block diagram**

Four I/O pins are dedicated to SPI communication with external devices.

- **MISO:** Master In / Slave Out data. In the general case, this pin is used to transmit data in slave mode and receive data in master mode.
- **MOSI:** Master Out / Slave In data. In the general case, this pin is used to transmit data in master mode and receive data in slave mode.
- **SCK:** Serial Clock output pin for SPI masters and input pin for SPI slaves.
- **NSS:** Slave select pin. Depending on the SPI and NSS settings, this pin can be used to either:
  - select an individual slave device for communication
  - synchronize the data frame or
  - detect a conflict between multiple masters

See [Section 42.4.5: Slave select \(NSS\) pin management](#) for details.

The SPI bus allows the communication between one master device and one or more slave devices. The bus consists of at least two wires - one for the clock signal and the other for synchronous data transfer. Other signals can be added depending on the data exchange between SPI nodes and their slave select signal management.

#### 42.4.2 Communications between one master and one slave

The SPI allows the MCU to communicate using different configurations, depending on the device targeted and the application requirements. These configurations use 2 or 3 wires (with software NSS management) or 3 or 4 wires (with hardware NSS management). Communication is always initiated by the master.

##### Full-duplex communication

By default, the SPI is configured for full-duplex communication. In this configuration, the shift registers of the master and slave are linked using two unidirectional lines between the MOSI and the MISO pins. During SPI communication, data is shifted synchronously on the SCK clock edges provided by the master. The master transmits the data to be sent to the slave via the MOSI line and receives data from the slave via the MISO line. When the data frame transfer is complete (all the bits are shifted) the information between the master and slave is exchanged.

**Figure 458. Full-duplex single master/ single slave application**

1. The NSS pins can be used to provide a hardware control flow between master and slave. Optionally, the pins can be left unused by the peripheral. Then the flow has to be handled internally for both master and slave. For more details see [Section 42.4.5: Slave select \(NSS\) pin management](#).

## Half-duplex communication

The SPI can communicate in half-duplex mode by setting the BIDIMODE bit in the SPIx\_CR1 register. In this configuration, one single cross connection line is used to link the shift registers of the master and slave together. During this communication, the data is synchronously shifted between the shift registers on the SCK clock edge in the transfer direction selected reciprocally by both master and slave with the BDIOE bit in their SPIx\_CR1 registers. In this configuration, the master's MISO pin and the slave's MOSI pin are free for other application uses and act as GPIOs.

**Figure 459. Half-duplex single master/ single slave application**

1. The NSS pins can be used to provide a hardware control flow between master and slave. Optionally, the pins can be left unused by the peripheral. Then the flow has to be handled internally for both master and slave. For more details see [Section 42.4.5: Slave select \(NSS\) pin management](#).
2. In this configuration, the master's MISO pin and the slave's MOSI pin can be used as GPIOs.
3. A critical situation can happen when communication direction is changed not synchronously between two nodes working at bidirectional mode and new transmitter accesses the common data line while former transmitter still keeps an opposite value on the line (the value depends on SPI configuration and communication data). Both nodes then fight while providing opposite output levels on the common line temporary till next node changes its direction settings correspondingly, too. It is suggested to insert a serial resistance between MISO and MOSI pins at this mode to protect the outputs and limit the current blowing between them at this situation.

## Simplex communications

The SPI can communicate in simplex mode by setting the SPI in transmit-only or in receive-only using the RXONLY bit in the SPIx\_CR1 register. In this configuration, only one line is used for the transfer between the shift registers of the master and slave. The remaining MISO and MOSI pins pair is not used for communication and can be used as standard GPIOs.

- **Transmit-only mode (RXONLY=0):** The configuration settings are the same as for full-duplex. The application has to ignore the information captured on the unused input pin. This pin can be used as a standard GPIO.
- **Receive-only mode (RXONLY=1):** The application can disable the SPI output function by setting the RXONLY bit. In slave configuration, the MISO output is disabled and the pin can be used as a GPIO. The slave continues to receive data from the MOSI pin while its slave select signal is active (see [42.4.5: Slave select \(NSS\) pin management](#)). Received data events appear depending on the data buffer configuration. In the master configuration, the MOSI output is disabled and the pin can be used as a GPIO. The clock signal is generated continuously as long as the SPI is enabled. The only way to stop the clock is to clear the RXONLY bit or the SPE bit and wait until the incoming pattern from the MISO pin is finished and fills the data buffer structure, depending on its configuration.

**Figure 460. Simplex single master/single slave application (master in transmit-only/ slave in receive-only mode)**

1. The NSS pins can be used to provide a hardware control flow between master and slave. Optionally, the pins can be left unused by the peripheral. Then the flow has to be handled internally for both master and slave. For more details see [Section 42.4.5: Slave select \(NSS\) pin management](#).
2. An accidental input information is captured at the input of transmitter Rx shift register. All the events associated with the transmitter receive flow must be ignored in standard transmit only mode (e.g. OVR flag).
3. In this configuration, both the MISO pins can be used as GPIOs.

**Note:** Any simplex communication can be alternatively replaced by a variant of the half-duplex communication with a constant setting of the transaction direction (bidirectional mode is enabled while BDIO bit is not changed).

### 42.4.3 Standard multislave communication

In a configuration with two or more independent slaves, the master uses GPIO pins to manage the chip select lines for each slave (see [Figure 461](#)). The master must select one of the slaves individually by pulling low the GPIO connected to the slave NSS input. When this is done, a standard master and dedicated slave communication is established.

Figure 461. Master and three independent slaves

MSv39626V1

1. NSS pin is not used on master side at this configuration. It has to be managed internally (SSM=1, SSI=1) to prevent any MODF error.
2. As MISO pins of the slaves are connected together, all slaves must have the GPIO configuration of their MISO pin set as alternate function open-drain (see I/O alternate function input/output section (GPIO)).

#### 42.4.4 Multimaster communication

Unless SPI bus is not designed for a multimaster capability primarily, the user can use build in feature which detects a potential conflict between two nodes trying to master the bus at the same time. For this detection, NSS pin is used configured at hardware input mode.

The connection of more than two SPI nodes working at this mode is impossible as only one node can apply its output on a common data line at time.

When nodes are non active, both stay at slave mode by default. Once one node wants to overtake control on the bus, it switches itself into master mode and applies active level on the slave select input of the other node via dedicated GPIO pin. After the session is completed, the active slave select signal is released and the node mastering the bus temporary returns back to passive slave mode waiting for next session start.

If potentially both nodes raised their mastering request at the same time a bus conflict event appears (see mode fault MODF event). Then the user can apply some simple arbitration process (e.g. to postpone next attempt by predefined different time-outs applied at both nodes).

Figure 462. Multimaster application

1. The NSS pin is configured at hardware input mode at both nodes. Its active level enables the MISO line output control as the passive node is configured as a slave.

#### 42.4.5 Slave select (NSS) pin management

In slave mode, the NSS works as a standard “chip select” input and lets the slave communicate with the master. In master mode, NSS can be used either as output or input. As an input it can prevent multimaster bus collision, and as an output it can drive a slave select signal of a single slave.

Hardware or software slave select management can be set using the SSM bit in the SPIx\_CR1 register:

- **Software NSS management (SSM = 1):** in this configuration, slave select information is driven internally by the SSI bit value in register SPIx\_CR1. The external NSS pin is free for other application uses.
- **Hardware NSS management (SSM = 0):** in this case, there are two possible configurations. The configuration used depends on the NSS output configuration (SSOE bit in register SPIx\_CR1).
  - **NSS output enable (SSM=0, SSOE = 1):** this configuration is only used when the MCU is set as master. The NSS pin is managed by the hardware. The NSS signal is driven low as soon as the SPI is enabled in master mode (SPE=1), and is kept low until the SPI is disabled (SPE =0). A pulse can be generated between continuous communications if NSS pulse mode is activated (NSSP=1). The SPI cannot work in multimaster configuration with this NSS setting.
  - **NSS output disable (SSM=0, SSOE = 0):** if the microcontroller is acting as the master on the bus, this configuration allows multimaster capability. If the NSS pin is pulled low in this mode, the SPI enters master mode fault state and the device is automatically reconfigured in slave mode. In slave mode, the NSS pin works as a standard “chip select” input and the slave is selected while NSS line is at low level.

Figure 463. Hardware/software slave select management

#### 42.4.6 Communication formats

During SPI communication, receive and transmit operations are performed simultaneously. The serial clock (SCK) synchronizes the shifting and sampling of the information on the data lines. The communication format depends on the clock phase, the clock polarity and the data frame format. To be able to communicate together, the master and slaves devices must follow the same communication format.

##### Clock phase and polarity controls

Four possible timing relationships may be chosen by software, using the CPOL and CPHA bits in the SPIx\_CR1 register. The CPOL (clock polarity) bit controls the idle state value of the clock when no data is being transferred. This bit affects both master and slave modes. If CPOL is reset, the SCK pin has a low-level idle state. If CPOL is set, the SCK pin has a high-level idle state.

If the CPHA bit is set, the second edge on the SCK pin captures the first data bit transacted (falling edge if the CPOL bit is reset, rising edge if the CPOL bit is set). Data are latched on each occurrence of this clock transition type. If the CPHA bit is reset, the first edge on the SCK pin captures the first data bit transacted (falling edge if the CPOL bit is set, rising edge if the CPOL bit is reset). Data are latched on each occurrence of this clock transition type.

The combination of CPOL (clock polarity) and CPHA (clock phase) bits selects the data capture clock edge.

[Figure 464](#), shows an SPI full-duplex transfer with the four combinations of the CPHA and CPOL bits.

**Note:** Prior to changing the CPOL/CPHA bits the SPI must be disabled by resetting the SPE bit. The idle state of SCK must correspond to the polarity selected in the SPIx\_CR1 register (by pulling up SCK if CPOL=1 or pulling down SCK if CPOL=0).

**Figure 464. Data clock timing diagram**

### Data frame format

The SPI shift register can be set up to shift out MSB-first or LSB-first, depending on the value of the LSBFIRST bit. The data frame size is chosen by using the DS bits. It can be set from 4-bit up to 16-bit length and the setting applies for both transmission and reception. Whatever the selected data frame size, read access to the FIFO must be aligned with the FRXTH level. When the SPIx\_DR register is accessed, data frames are always right-aligned into either a byte (if the data fits into a byte) or a half-word (see [Figure 465](#)). During communication, only bits within the data frame are clocked and transferred.

**Figure 465. Data alignment when data length is not equal to 8-bit or 16-bit**

**Note:** The minimum data length is 4 bits. If a data length of less than 4 bits is selected, it is forced to an 8-bit data frame size.

#### 42.4.7 Configuration of SPI

The configuration procedure is almost the same for master and slave. For specific mode setups, follow the dedicated sections. When a standard communication is to be initialized, perform these steps:

1. Write proper GPIO registers: Configure GPIO for MOSI, MISO and SCK pins.
2. Write to the SPI\_CR1 register:
  - a) Configure the serial clock baud rate using the BR[2:0] bits (Note: 4).
  - b) Configure the CPOL and CPHA bits combination to define one of the four relationships between the data transfer and the serial clock (CPHA must be cleared in NSSP mode). (Note: 2 - except the case when CRC is enabled at TI mode).
  - c) Select simplex or half-duplex mode by configuring RXONLY or BIDIMODE and BIDIOE (RXONLY and BIDIMODE cannot be set at the same time).
  - d) Configure the LSBFIRST bit to define the frame format (Note: 2).
  - e) Configure the CRCL and CRCEN bits if CRC is needed (while SCK clock signal is at idle state).
  - f) Configure SSM and SSI (Notes: 2 & 3).
  - g) Configure the MSTR bit (in multimaster NSS configuration, avoid conflict state on NSS if master is configured to prevent MODF error).
3. Write to SPI\_CR2 register:
  - a) Configure the DS[3:0] bits to select the data length for the transfer.
  - b) Configure SSOE (Notes: 1 & 2 & 3).
  - c) Set the FRF bit if the TI protocol is required (keep NSSP bit cleared in TI mode).
  - d) Set the NSSP bit if the NSS pulse mode between two data units is required (keep CPHA and TI bits cleared in NSSP mode).
  - e) Configure the FRXTH bit. The RXFIFO threshold must be aligned to the read access size for the SPIx\_DR register.
  - f) Initialize LDMA\_TX and LDMA\_RX bits if DMA is used in packed mode.
4. Write to SPI\_CRCPR register: Configure the CRC polynomial if needed.
5. Write proper DMA registers: Configure DMA streams dedicated for SPI Tx and Rx in DMA registers if the DMA streams are used.

*Note:*

- (1) Step is not required in slave mode.
- (2) Step is not required in TI mode.
- (3) Step is not required in NSSP mode.
- (4) The step is not required in slave mode except slave working at TI mode

#### 42.4.8 Procedure for enabling SPI

It is recommended to enable the SPI slave before the master sends the clock. If not, undesired data transmission might occur. The data register of the slave must already contain data to be sent before starting communication with the master (either on the first edge of the communication clock, or before the end of the ongoing communication if the clock signal is continuous). The SCK signal must be settled at an idle state level corresponding to the selected polarity before the SPI slave is enabled.

The master at full-duplex (or in any transmit-only mode) starts to communicate when the SPI is enabled and TXFIFO is not empty, or with the next write to TXFIFO.

In any master receive only mode (RXONLY = 1 or BIDIMODE = 1 & BIDIOE = 0), master starts to communicate and the clock starts running immediately after SPI is enabled.

For handling DMA, follow the dedicated section.

#### 42.4.9 Data transmission and reception procedures

##### RXFIFO and TXFIFO

All SPI data transactions pass through the 32-bit embedded FIFOs. This enables the SPI to work in a continuous flow, and prevents overruns when the data frame size is short. Each direction has its own FIFO called TXFIFO and RXFIFO. These FIFOs are used in all SPI modes except for receiver-only mode (slave or master) with CRC calculation enabled (see [Section 42.4.14: CRC calculation](#)).

The handling of FIFOs depends on the data exchange mode (duplex, simplex), data frame format (number of bits in the frame), access size performed on the FIFO data registers (8-bit or 16-bit), and whether or not data packing is used when accessing the FIFOs (see [Section 42.4.13: TI mode](#)).

A read access to the SPIx\_DR register returns the oldest value stored in RXFIFO that has not been read yet. A write access to the SPIx\_DR stores the written data in the TXFIFO at the end of a send queue. The read access must be always aligned with the RXFIFO threshold configured by the FRXTH bit in SPIx\_CR2 register. FTLVL[1:0] and FRLVL[1:0] bits indicate the current occupancy level of both FIFOs.

A read access to the SPIx\_DR register must be managed by the RXNE event. This event is triggered when data is stored in RXFIFO and the threshold (defined by FRXTH bit) is reached. When RXNE is cleared, RXFIFO is considered to be empty. In a similar way, write access of a data frame to be transmitted is managed by the TXE event. This event is triggered when the TXFIFO level is less than or equal to half of its capacity. Otherwise TXE is cleared and the TXFIFO is considered as full. In this way, RXFIFO can store up to four data frames, whereas TXFIFO can only store up to three when the data frame format is not greater than 8 bits. This difference prevents possible corruption of 3x 8-bit data frames already stored in the TXFIFO when software tries to write more data in 16-bit mode into TXFIFO. Both TXE and RXNE events can be polled or handled by interrupts. See [Figure 467](#) through [Figure 470](#).

Another way to manage the data exchange is to use DMA (see [Communication using DMA \(direct memory addressing\)](#)).

If the next data is received when the RXFIFO is full, an overrun event occurs (see description of OVR flag at [Section 42.4.10: SPI status flags](#)). An overrun event can be polled or handled by an interrupt.

The BSY bit being set indicates ongoing transaction of a current data frame. When the clock signal runs continuously, the BSY flag stays set between data frames at master but becomes low for a minimum duration of one SPI clock at slave between each data frame transfer.

### Sequence handling

A few data frames can be passed at single sequence to complete a message. When transmission is enabled, a sequence begins and continues while any data is present in the TXFIFO of the master. The clock signal is provided continuously by the master until TXFIFO becomes empty, then it stops waiting for additional data.

In receive-only modes, half-duplex (BIDIMODE=1, BIDIOE=0) or simplex (BIDIMODE=0, RXONLY=1) the master starts the sequence immediately when both SPI is enabled and receive-only mode is activated. The clock signal is provided by the master and it does not stop until either SPI or receive-only mode is disabled by the master. The master receives data frames continuously up to this moment.

While the master can provide all the transactions in continuous mode (SCK signal is continuous) it has to respect slave capability to handle data flow and its content at anytime. When necessary, the master must slow down the communication and provide either a slower clock or separate frames or data sessions with sufficient delays. Be aware there is no underflow error signal for master or slave in SPI mode, and data from the slave is always transacted and processed by the master even if the slave could not prepare it correctly in time. It is preferable for the slave to use DMA, especially when data frames are shorter and bus rate is high.

Each sequence must be encased by the NSS pulse in parallel with the multislave system to select just one of the slaves for communication. In a single slave system it is not necessary to control the slave with NSS, but it is often better to provide the pulse here too, to synchronize the slave with the beginning of each data sequence. NSS can be managed by both software and hardware (see [Section 42.4.5: Slave select \(NSS\) pin management](#)).

When the BSY bit is set it signifies an ongoing data frame transaction. When the dedicated frame transaction is finished, the RXNE flag is raised. The last bit is just sampled and the complete data frame is stored in the RXFIFO.

### Procedure for disabling the SPI

When SPI is disabled, it is mandatory to follow the disable procedures described in this paragraph. It is important to do this before the system enters a low-power mode when the peripheral clock is stopped. Ongoing transactions can be corrupted in this case. In some modes the disable procedure is the only way to stop continuous communication running.

Master in full-duplex or transmit only mode can finish any transaction when it stops providing data for transmission. In this case, the clock stops after the last data transaction. Special care must be taken in packing mode when an odd number of data frames are transacted to prevent some dummy byte exchange (refer to [Data packing](#) section). Before the SPI is disabled in these modes, the user must follow standard disable procedure. When

the SPI is disabled at the master transmitter while a frame transaction is ongoing or next data frame is stored in TXFIFO, the SPI behavior is not guaranteed.

When the master is in any receive only mode, the only way to stop the continuous clock is to disable the peripheral by SPE=0. This must occur in specific time window within last data frame transaction just between the sampling time of its first bit and before its last bit transfer starts (in order to receive a complete number of expected data frames and to prevent any additional “dummy” data reading after the last valid data frame). Specific procedure must be followed when disabling SPI in this mode.

Data received but not read remains stored in RXFIFO when the SPI is disabled, and must be processed the next time the SPI is enabled, before starting a new sequence. To prevent having unread data, ensure that RXFIFO is empty when disabling the SPI, by using the correct disabling procedure, or by initializing all the SPI registers with a software reset via the control of a specific register dedicated to peripheral reset (see the SPIIRST bits in the RCC\_APB1RSTR registers).

Standard disable procedure is based on pulling BSY status together with FTLVL[1:0] to check if a transmission session is fully completed. This check can be done in specific cases, too, when it is necessary to identify the end of ongoing transactions, for example:

- When NSS signal is managed by software and master has to provide proper end of NSS pulse for slave, or
- When transactions' streams from DMA or FIFO are completed while the last data frame or CRC frame transaction is still ongoing in the peripheral bus.

The correct disable procedure is (except when receive only mode is used):

1. Wait until FTLVL[1:0] = 00 (no more data to transmit).
2. Wait until BSY=0 (the last data frame is processed).
3. Disable the SPI (SPE=0).
4. Read data until FRLVL[1:0] = 00 (read all the received data).

The correct disable procedure for certain receive only modes is:

1. Interrupt the receive flow by disabling SPI (SPE=0) in the specific time window while the last data frame is ongoing.
2. Wait until BSY=0 (the last data frame is processed).
3. Read data until FRLVL[1:0] = 00 (read all the received data).

**Note:** *If packing mode is used and an odd number of data frames with a format less than or equal to 8 bits (fitting into one byte) has to be received, FRXTH must be set when FRLVL[1:0] = 01, in order to generate the RXNE event to read the last odd data frame and to keep good FIFO pointer alignment.*

### Data packing

When the data frame size fits into one byte (less than or equal to 8 bits), data packing is used automatically when any read or write 16-bit access is performed on the SPIx\_DR register. The double data frame pattern is handled in parallel in this case. At first, the SPI operates using the pattern stored in the LSB of the accessed word, then with the other half stored in the MSB. [Figure 466](#) provides an example of data packing mode sequence handling. Two data frames are sent after the single 16-bit access the SPIx\_DR register of the transmitter. This sequence can generate just one RXNE event in the receiver if the RXFIFO threshold is set to 16 bits (FRXTH=0). The receiver then has to access both data frames by a single 16-bit read of SPIx\_DR as a response to this single RXNE event. The

RxFIFO threshold setting and the following read access must be always kept aligned at the receiver side, as data can be lost if it is not in line.

A specific problem appears if an odd number of such “fit into one byte” data frames must be handled. On the transmitter side, writing the last data frame of any odd sequence with an 8-bit access to SPIx\_DR is enough. The receiver has to change the Rx\_FIFO threshold level for the last data frame received in the odd sequence of frames in order to generate the RXNE event.

**Figure 466. Packing data in FIFO for transmission and reception**

### Communication using DMA (direct memory addressing)

To operate at its maximum speed and to facilitate the data register read/write process required to avoid overrun, the SPI features a DMA capability, which implements a simple request/acknowledge protocol.

A DMA access is requested when the TXDMAEN or RXDMAEN enable bit in the SPIx\_CR2 register is set. Separate requests must be issued to the Tx and Rx buffers.

- In transmission, a DMA request is issued each time TXE is set to 1. The DMA then writes to the SPIx\_DR register.
- In reception, a DMA request is issued each time RXNE is set to 1. The DMA then reads the SPIx\_DR register.

See [Figure 467](#) through [Figure 470](#).

When the SPI is used only to transmit data, it is possible to enable only the SPI Tx DMA channel. In this case, the OVR flag is set because the data received is not read. When the SPI is used only to receive data, it is possible to enable only the SPI Rx DMA channel.

In transmission mode, when the DMA has written all the data to be transmitted (the TCIF flag is set in the DMA\_ISR register), the BSY flag can be monitored to ensure that the SPI communication is complete. This is required to avoid corrupting the last transmission before disabling the SPI or entering the Stop mode. The software must first wait until FTLVL[1:0]=00 and then until BSY=0.

When starting communication using DMA, to prevent DMA channel management raising error events, these steps must be followed in order:

1. Enable DMA Rx buffer in the RXDMAEN bit in the SPI\_CR2 register, if DMA Rx is used.
2. Enable DMA streams for Tx and Rx in DMA registers, if the streams are used.
3. Enable DMA Tx buffer in the TXDMAEN bit in the SPI\_CR2 register, if DMA Tx is used.
4. Enable the SPI by setting the SPE bit.

To close communication it is mandatory to follow these steps in order:

1. Disable DMA streams for Tx and Rx in the DMA registers, if the streams are used.
2. Disable the SPI by following the SPI disable procedure.
3. Disable DMA Tx and Rx buffers by clearing the TXDMAEN and RXDMAEN bits in the SPI\_CR2 register, if DMA Tx and/or DMA Rx are used.

### Packing with DMA

If the transfers are managed by DMA (TXDMAEN and RXDMAEN set in the SPIx\_CR2 register) packing mode is enabled/disabled automatically depending on the PSIZE value configured for SPI TX and the SPI RX DMA channel. If the DMA channel PSIZE value is equal to 16-bit and SPI data size is less than or equal to 8-bit, then packing mode is enabled. The DMA then automatically manages the write operations to the SPIx\_DR register.

If data packing mode is used and the number of data to transfer is not a multiple of two, the LDMA\_TX/LDMA\_RX bits must be set. The SPI then considers only one data for the transmission or reception to serve the last DMA transfer (for more details refer to [Data packing on page 1444](#).)

## Communication diagrams

Some typical timing schemes are explained in this section. These schemes are valid no matter if the SPI events are handled by polling, interrupts or DMA. For simplicity, the LSBFIRST=0, CPOL=0 and CPHA=1 setting is used as a common assumption here. No complete configuration of DMA streams is provided.

The following numbered notes are common for [Figure 467 on page 1448](#) through [Figure 470 on page 1451](#):

1. The slave starts to control MISO line as NSS is active and SPI is enabled, and is disconnected from the line when one of them is released. Sufficient time must be provided for the slave to prepare data dedicated to the master in advance before its transaction starts.  
At the master, the SPI peripheral takes control at MOSI and SCK signals (occasionally at NSS signal as well) only if SPI is enabled. If SPI is disabled the SPI peripheral is disconnected from GPIO logic, so the levels at these lines depends on GPIO setting exclusively.
2. At the master, BSY stays active between frames if the communication (clock signal) is continuous. At the slave, BSY signal always goes down for at least one clock cycle between data frames.
3. The TXE signal is cleared only if TXFIFO is full.
4. The DMA arbitration process starts just after the TXDMAEN bit is set. The TXE interrupt is generated just after the TXEIE is set. As the TXE signal is at an active level, data transfers to TxFIFO start, until TxFIFO becomes full or the DMA transfer completes.
5. If all the data to be sent can fit into TxFIFO, the DMA Tx TCIF flag can be raised even before communication on the SPI bus starts. This flag always rises before the SPI transaction is completed.
6. The CRC value for a package is calculated continuously frame by frame in the SPIx\_TXCRCR and SPIx\_RXCRCR registers. The CRC information is processed after the entire data package has completed, either automatically by DMA (Tx channel must be set to the number of data frames to be processed) or by SW (the user must handle CRCNEXT bit during the last data frame processing).  
While the CRC value calculated in SPIx\_TXCRCR is simply sent out by transmitter, received CRC information is loaded into RxFIFO and then compared with the SPIx\_RXCRCR register content (CRC error flag can be raised here if any difference). This is why the user must take care to flush this information from the FIFO, either by software reading out all the stored content of RxFIFO, or by DMA when the proper number of data frames is preset for Rx channel (number of data frames + number of CRC frames) (see the settings at the example assumption).
7. In data packed mode, TxE and RxNE events are paired and each read/write access to the FIFO is 16 bits wide until the number of data frames are even. If the TxFIFO is  $\frac{3}{4}$  full FTLVL status stays at FIFO full level. That is why the last odd data frame cannot be stored before the TxFIFO becomes  $\frac{1}{2}$  full. This frame is stored into TxFIFO with an 8-bit access either by software or automatically by DMA when LDMA\_TX control is set.
8. To receive the last odd data frame in packed mode, the Rx threshold must be changed to 8-bit when the last data frame is processed, either by software setting FRXTH=1 or automatically by a DMA internal signal when LDMA\_RX is set.

Figure 467. Master full-duplex communication

Assumptions for master full-duplex communication example:

- Data size > 8 bit

If DMA is used:

- Number of Tx frames transacted by DMA is set to 3
- Number of Rx frames transacted by DMA is set to 3

See also : [Communication diagrams on page 1447](#) for details about common assumptions and notes.

Figure 468. Slave full-duplex communication

Assumptions for slave full-duplex communication example:

- Data size > 8 bit

If DMA is used:

- Number of Tx frames transacted by DMA is set to 3
- Number of Rx frames transacted by DMA is set to 3

See also [Communication diagrams on page 1447](#) for details about common assumptions and notes.

Figure 469. Master full-duplex communication with CRC

Assumptions for master full-duplex communication with CRC example:

- Data size = 16 bit
- CRC enabled

If DMA is used:

- Number of Tx frames transacted by DMA is set to 2
- Number of Rx frames transacted by DMA is set to 3

See also : [Communication diagrams on page 1447](#) for details about common assumptions and notes.

Figure 470. Master full-duplex communication in packed mode

Assumptions for master full-duplex communication in packed mode example:

- Data size = 5 bit
- Read/write FIFO is performed mostly by 16-bit access
- FRXTH=0

If DMA is used:

- Number of Tx frames to be transacted by DMA is set to 3
- Number of Rx frames to be transacted by DMA is set to 3
- PSIZE for both Tx and Rx DMA channel is set to 16-bit
- LDMA\_TX=1 and LDMA\_RX=1

See also : [Communication diagrams on page 1447](#) for details about common assumptions and notes.

#### 42.4.10 SPI status flags

Three status flags are provided for the application to completely monitor the state of the SPI bus.

##### **Tx buffer empty flag (TXE)**

The TXE flag is set when transmission TXFIFO has enough space to store data to send. TXE flag is linked to the TXFIFO level. The flag goes high and stays high until the TXFIFO level is lower or equal to 1/2 of the FIFO depth. An interrupt can be generated if the TXEIE bit in the SPIx\_CR2 register is set. The bit is cleared automatically when the TXFIFO level becomes greater than 1/2.

##### **Rx buffer not empty (RXNE)**

The RXNE flag is set depending on the FRXTH bit value in the SPIx\_CR2 register:

- If FRXTH is set, RXNE goes high and stays high until the RXFIFO level is greater or equal to 1/4 (8-bit).
- If FRXTH is cleared, RXNE goes high and stays high until the RXFIFO level is greater than or equal to 1/2 (16-bit).

An interrupt can be generated if the RXNEIE bit in the SPIx\_CR2 register is set.

The RXNE is cleared by hardware automatically when the above conditions are no longer true.

##### **Busy flag (BSY)**

The BSY flag is set and cleared by hardware (writing to this flag has no effect).

When BSY is set, it indicates that a data transfer is in progress on the SPI (the SPI bus is busy).

The BSY flag can be used in certain modes to detect the end of a transfer so that the software can disable the SPI or its peripheral clock before entering a low-power mode which does not provide a clock for the peripheral. This avoids corrupting the last transfer.

The BSY flag is also useful for preventing write collisions in a multimaster system.

The BSY flag is cleared under any one of the following conditions:

- When the SPI is correctly disabled
- When a fault is detected in Master mode (MODF bit set to 1)
- In Master mode, when it finishes a data transmission and no new data is ready to be sent
- In Slave mode, when the BSY flag is set to '0' for at least one SPI clock cycle between each data transfer.

*Note:* When the next transmission can be handled immediately by the master (e.g. if the master is in Receive-only mode or its Transmit FIFO is not empty), communication is continuous and the BSY flag remains set to '1' between transfers on the master side. Although this is not the case with a slave, it is recommended to use always the TXE and RXNE flags (instead of the BSY flags) to handle data transmission or reception operations.

### 42.4.11 SPI error flags

An SPI interrupt is generated if one of the following error flags is set and interrupt is enabled by setting the ERRIE bit.

#### Overrun flag (OVR)

An overrun condition occurs when data is received by a master or slave and the RXFIFO has not enough space to store this received data. This can happen if the software or the DMA did not have enough time to read the previously received data (stored in the RXFIFO) or when space for data storage is limited e.g. the RXFIFO is not available when CRC is enabled in receive only mode so in this case the reception buffer is limited into a single data frame buffer (see [Section 42.4.14: CRC calculation](#)).

When an overrun condition occurs, the newly received value does not overwrite the previous one in the RXFIFO. The newly received value is discarded and all data transmitted subsequently is lost. Clearing the OVR bit is done by a read access to the SPI\_DR register followed by a read access to the SPI\_SR register.

#### Mode fault (MODF)

Mode fault occurs when the master device has its internal NSS signal (NSS pin in NSS hardware mode, or SSI bit in NSS software mode) pulled low. This automatically sets the MODF bit. Master mode fault affects the SPI interface in the following ways:

- The MODF bit is set and an SPI interrupt is generated if the ERRIE bit is set.
- The SPE bit is cleared. This blocks all output from the device and disables the SPI interface.
- The MSTR bit is cleared, thus forcing the device into slave mode.

Use the following software sequence to clear the MODF bit:

1. Make a read or write access to the SPIx\_SR register while the MODF bit is set.
2. Then write to the SPIx\_CR1 register.

To avoid any multiple slave conflicts in a system comprising several MCUs, the NSS pin must be pulled high during the MODF bit clearing sequence. The SPE and MSTR bits can be restored to their original state after this clearing sequence. As a security, hardware does not allow the SPE and MSTR bits to be set while the MODF bit is set. In a slave device the MODF bit cannot be set except as the result of a previous multimaster conflict.

#### CRC error (CRCERR)

This flag is used to verify the validity of the value received when the CRCEN bit in the SPIx\_CR1 register is set. The CRCERR flag in the SPIx\_SR register is set if the value received in the shift register does not match the receiver SPIx\_RXCRCR value. The flag is cleared by the software.

#### TI mode frame format error (FRE)

A TI mode frame format error is detected when an NSS pulse occurs during an ongoing communication when the SPI is operating in slave mode and configured to conform to the TI mode protocol. When this error occurs, the FRE flag is set in the SPIx\_SR register. The SPI is not disabled when an error occurs, the NSS pulse is ignored, and the SPI waits for the next NSS pulse before starting a new transfer. The data may be corrupted since the error detection may result in the loss of two data bytes.

The FRE flag is cleared when SPIx\_SR register is read. If the ERRIE bit is set, an interrupt is generated on the NSS error detection. In this case, the SPI should be disabled because data consistency is no longer guaranteed and communications should be reinitiated by the master when the slave SPI is enabled again.

#### 42.4.12 NSS pulse mode

This mode is activated by the NSSP bit in the SPIx\_CR2 register and it takes effect only if the SPI interface is configured as Motorola SPI master (FRF=0) with capture on the first edge (SPIx\_CR1 CPHA = 0, CPOL setting is ignored). When activated, an NSS pulse is generated between two consecutive data frame transfers when NSS stays at high level for the duration of one clock period at least. This mode allows the slave to latch data. NSSP pulse mode is designed for applications with a single master-slave pair.

Figure 471 illustrates NSS pin management when NSSP pulse mode is enabled.

**Figure 471. NSSP pulse generation in Motorola SPI master mode**

**Note:** Similar behavior is encountered when CPOL = 0. In this case the sampling edge is the *rising* edge of SCK, and NSS assertion and deassertion refer to this sampling edge.

#### 42.4.13 TI mode

##### TI protocol in master mode

The SPI interface is compatible with the TI protocol. The FRF bit of the SPIx\_CR2 register can be used to configure the SPI to be compliant with this protocol.

The clock polarity and phase are forced to conform to the TI protocol requirements whatever the values set in the SPIx\_CR1 register. NSS management is also specific to the TI protocol which makes the configuration of NSS management through the SPIx\_CR1 and SPIx\_CR2 registers (SSM, SSI, SSOE) impossible in this case.

In slave mode, the SPI baud rate prescaler is used to control the moment when the MISO pin state changes to HiZ when the current transaction finishes (see Figure 472). Any baud rate can be used, making it possible to determine this moment with optimal flexibility. However, the baud rate is generally set to the external master clock baud rate. The delay for the MISO signal to become HiZ ( $t_{release}$ ) depends on internal resynchronization and on the

baud rate value set in through the BR[2:0] bits in the SPIx\_CR1 register. It is given by the formula:

$$\frac{t_{\text{baud\_rate}}}{2} + 4 \times t_{\text{pclk}} < t_{\text{release}} < \frac{t_{\text{baud\_rate}}}{2} + 6 \times t_{\text{pclk}}$$

If the slave detects a misplaced NSS pulse during a data frame transaction the TIFRE flag is set.

If the data size is equal to 4-bits or 5-bits, the master in full-duplex mode or transmit-only mode uses a protocol with one more dummy data bit added after LSB. TI NSS pulse is generated above this dummy bit clock cycle instead of the LSB in each period.

This feature is not available for Motorola SPI communications (FRF bit set to 0).

*Figure 472: TI mode transfer* shows the SPI communication waveforms when TI mode is selected.

**Figure 472. TI mode transfer**

#### 42.4.14 CRC calculation

Two separate CRC calculators are implemented in order to check the reliability of transmitted and received data. The SPI offers CRC8 or CRC16 calculation independently of the frame data length, which can be fixed to 8-bit or 16-bit. For all the other data frame lengths, no CRC is available.

##### CRC principle

CRC calculation is enabled by setting the CRCEN bit in the SPIx\_CR1 register before the SPI is enabled (SPE = 1). The CRC value is calculated using an odd programmable polynomial on each bit. The calculation is processed on the sampling clock edge defined by the CPHA and CPOL bits in the SPIx\_CR1 register. The calculated CRC value is checked automatically at the end of the data block as well as for transfer managed by CPU or by the DMA. When a mismatch is detected between the CRC calculated internally on the received data and the CRC sent by the transmitter, a CRCERR flag is set to indicate a data corruption error. The right procedure for handling the CRC calculation depends on the SPI configuration and the chosen transfer management.

*Note:* The polynomial value should only be odd. No even values are supported.

### CRC transfer managed by CPU

Communication starts and continues normally until the last data frame has to be sent or received in the SPIx\_DR register. Then CRCNEXT bit has to be set in the SPIx\_CR1 register to indicate that the CRC frame transaction follows after the transaction of the currently processed data frame. The CRCNEXT bit must be set before the end of the last data frame transaction. CRC calculation is frozen during CRC transaction.

The received CRC is stored in the RXFIFO like a data byte or word. That is why in CRC mode only, the reception buffer has to be considered as a single 16-bit buffer used to receive only one data frame at a time.

A CRC-format transaction usually takes one more data frame to communicate at the end of data sequence. However, when setting an 8-bit data frame checked by 16-bit CRC, two more frames are necessary to send the complete CRC.

When the last CRC data is received, an automatic check is performed comparing the received value and the value in the SPIx\_RXCRC register. Software has to check the CRCERR flag in the SPIx\_SR register to determine if the data transfers were corrupted or not. Software clears the CRCERR flag by writing '0' to it.

After the CRC reception, the CRC value is stored in the RXFIFO and must be read in the SPIx\_DR register in order to clear the RXNE flag.

### CRC transfer managed by DMA

When SPI communication is enabled with CRC communication and DMA mode, the transmission and reception of the CRC at the end of communication is automatic (with the exception of reading CRC data in receive only mode). The CRCNEXT bit does not have to be handled by the software. The counter for the SPI transmission DMA channel has to be set to the number of data frames to transmit excluding the CRC frame. On the receiver side, the received CRC value is handled automatically by DMA at the end of the transaction but user must take care to flush out received CRC information from RXFIFO as it is always loaded into it. In full-duplex mode, the counter of the reception DMA channel can be set to the number of data frames to receive including the CRC, which means, for example, in the specific case of an 8-bit data frame checked by 16-bit CRC:

$$\text{DMA\_RX} = \text{Numb\_of\_data} + 2$$

In receive only mode, the DMA reception channel counter should contain only the amount of data transferred, excluding the CRC calculation. Then based on the complete transfer from DMA, all the CRC values must be read back by software from FIFO as it works as a single buffer in this mode.

At the end of the data and CRC transfers, the CRCERR flag in the SPIx\_SR register is set if corruption occurred during the transfer.

If packing mode is used, the LDMA\_RX bit needs managing if the number of data is odd.

### Resetting the SPIx\_TXCRC and SPIx\_RXCRC values

The SPIx\_TXCRC and SPIx\_RXCRC values are cleared automatically when new data is sampled after a CRC phase. This allows the use of DMA circular mode (not available in receive-only mode) in order to transfer data without any interruption, (several data blocks covered by intermediate CRC checking phases).

If the SPI is disabled during a communication the following sequence must be followed:

1. Disable the SPI
2. Clear the CRCEN bit
3. Enable the CRCEN bit
4. Enable the SPI

**Note:** *When the SPI interface is configured as a slave, the NSS internal signal needs to be kept low during transaction of the CRC phase once the CRCNEXT signal is released. That is why the CRC calculation cannot be used at NSS Pulse mode when NSS hardware mode should be applied at slave normally.*

*At TI mode, despite the fact that clock phase and clock polarity setting is fixed and independent on SPIx\_CR1 register, the corresponding setting CPOL=0 CPHA=1 has to be kept at the SPIx\_CR1 register anyway if CRC is applied. In addition, the CRC calculation has to be reset between sessions by SPI disable sequence with re-enable the CRCEN bit described above at both master and slave side, else CRC calculation can be corrupted at this specific mode.*

## 42.5 SPI interrupts

During SPI communication an interrupt can be generated by the following events:

- Transmit TXFIFO ready to be loaded
- Data received in Receive RXFIFO
- Master mode fault
- Overrun error
- TI frame format error
- CRC protocol error

Interrupts can be enabled and disabled separately.

**Table 265. SPI interrupt requests**

| Interrupt event                    | Event flag | Enable Control bit |
|------------------------------------|------------|--------------------|
| Transmit TXFIFO ready to be loaded | TXE        | TXEIE              |
| Data received in RXFIFO            | RXNE       | RXNEIE             |
| Master Mode fault event            | MODF       | ERRIE              |
| Overrun error                      | OVR        |                    |
| TI frame format error              | FRE        |                    |
| CRC protocol error                 | CRCERR     |                    |

## 42.6 SPI registers

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit). SPI\_DR in addition can be accessed by 8-bit access.

### 42.6.1 SPI control register 1 (SPIx\_CR1)

Address offset: 0x00

Reset value: 0x0000

| 15           | 14     | 13        | 12          | 11   | 10         | 9   | 8   | 7            | 6   | 5       | 4  | 3  | 2    | 1    | 0    |
|--------------|--------|-----------|-------------|------|------------|-----|-----|--------------|-----|---------|----|----|------|------|------|
| BIDI<br>MODE | BIDIOE | CRC<br>EN | CRCN<br>EXT | CRCL | RX<br>ONLY | SSM | SSI | LSB<br>FIRST | SPE | BR[2:0] |    |    | MSTR | CPOL | CPHA |
| rW           | rW     | rW        | rW          | rW   | rW         | rW  | rW  | rW           | rW  | rW      | rW | rW | rW   | rW   | rW   |

Bit 15 **BIDIMODE**: Bidirectional data mode enable.

This bit enables half-duplex communication using common single bidirectional data line.  
Keep RXONLY bit clear when bidirectional mode is active.

0: 2-line unidirectional data mode selected

1: 1-line bidirectional data mode selected

Bit 14 **BIDIOE**: Output enable in bidirectional mode

This bit combined with the BIDIMODE bit selects the direction of transfer in bidirectional mode.

0: Output disabled (receive-only mode)

1: Output enabled (transmit-only mode)

*Note: In master mode, the MOSI pin is used and in slave mode, the MISO pin is used.*

Bit 13 **CRCEN**: Hardware CRC calculation enable

0: CRC calculation disabled

1: CRC calculation enabled

*Note: This bit should be written only when SPI is disabled (SPE = '0') for correct operation.*

Bit 12 **CRCNEXT**: Transmit CRC next

0: Next transmit value is from Tx buffer.

1: Next transmit value is from Tx CRC register.

*Note: This bit has to be written as soon as the last data is written in the SPIx\_DR register.*

Bit 11 **CRCL**: CRC length

This bit is set and cleared by software to select the CRC length.

0: 8-bit CRC length

1: 16-bit CRC length

*Note: This bit should be written only when SPI is disabled (SPE = '0') for correct operation.*

Bit 10 **RXONLY**: Receive only mode enabled.

This bit enables simplex communication using a single unidirectional line to receive data exclusively. Keep BIDIMODE bit clear when receive only mode is active. This bit is also useful in a multislave system in which this particular slave is not accessed, the output from the accessed slave is not corrupted.

0: Full-duplex (Transmit and receive)

1: Output disabled (Receive-only mode)

Bit 9 **SSM**: Software slave management

When the SSM bit is set, the NSS pin input is replaced with the value from the SSI bit.

0: Software slave management disabled

1: Software slave management enabled

*Note: This bit is not used in SPI TI mode.*

Bit 8 **SSI**: Internal slave select

This bit has an effect only when the SSM bit is set. The value of this bit is forced onto the NSS pin and the I/O value of the NSS pin is ignored.

*Note: This bit is not used in SPI TI mode.*

Bit 7 **LSBFIRST**: Frame format

0: data is transmitted / received with the MSB first

1: data is transmitted / received with the LSB first

*Note: 1. This bit should not be changed when communication is ongoing.*

*2. This bit is not used in SPI TI mode.*

Bit 6 **SPE**: SPI enable

0: Peripheral disabled

1: Peripheral enabled

*Note: When disabling the SPI, follow the procedure described in [Procedure for disabling the SPI on page 1443](#).*

Bits 5:3 **BR[2:0]**: Baud rate control

000:  $f_{PCLK}/2$

001:  $f_{PCLK}/4$

010:  $f_{PCLK}/8$

011:  $f_{PCLK}/16$

100:  $f_{PCLK}/32$

101:  $f_{PCLK}/64$

110:  $f_{PCLK}/128$

111:  $f_{PCLK}/256$

*Note: These bits should not be changed when communication is ongoing.*

Bit 2 **MSTR**: Master selection

0: Slave configuration

1: Master configuration

*Note: This bit should not be changed when communication is ongoing.*

Bit 1 **CPOL**: Clock polarity

0: CK to 0 when idle

1: CK to 1 when idle

*Note: This bit should not be changed when communication is ongoing.*

*This bit is not used in SPI TI mode except the case when CRC is applied at TI mode.*

Bit 0 **CPHA**: Clock phase

0: The first clock transition is the first data capture edge

1: The second clock transition is the first data capture edge

*Note: This bit should not be changed when communication is ongoing.*

*This bit is not used in SPI TI mode except the case when CRC is applied at TI mode.*

## 42.6.2 SPI control register 2 (SPIx\_CR2)

Address offset: 0x04

Reset value: 0x0700

| 15   | 14      | 13      | 12    | 11      | 10 | 9  | 8  | 7     | 6      | 5     | 4   | 3    | 2    | 1       | 0       |
|------|---------|---------|-------|---------|----|----|----|-------|--------|-------|-----|------|------|---------|---------|
| Res. | LDMA_TX | LDMA_RX | FRXTH | DS[3:0] |    |    |    | TXEIE | RXNEIE | ERRIE | FRF | NSSP | SSOE | TXDMAEN | RXDMAEN |
|      | rw      | rw      | rw    | rw      | rw | rw | rw | rw    | rw     | rw    | rw  | rw   | rw   | rw      | rw      |

Bit 15 Reserved, must be kept at reset value.

Bit 14 **LDMA\_TX**: Last DMA transfer for transmission

This bit is used in data packing mode, to define if the total number of data to transmit by DMA is odd or even. It has significance only if the TXDMAEN bit in the SPIx\_CR2 register is set and if packing mode is used (data length  $\leq$  8-bit and write access to SPIx\_DR is 16-bit wide). It has to be written when the SPI is disabled (SPE = 0 in the SPIx\_CR1 register).

0: Number of data to transfer is even

1: Number of data to transfer is odd

*Note: Refer to [Procedure for disabling the SPI on page 1443](#) if the CRCEN bit is set.*

Bit 13 **LDMA\_RX**: Last DMA transfer for reception

This bit is used in data packing mode, to define if the total number of data to receive by DMA is odd or even. It has significance only if the RXDMAEN bit in the SPIx\_CR2 register is set and if packing mode is used (data length  $\leq$  8-bit and write access to SPIx\_DR is 16-bit wide). It has to be written when the SPI is disabled (SPE = 0 in the SPIx\_CR1 register).

0: Number of data to transfer is even

1: Number of data to transfer is odd

*Note: Refer to [Procedure for disabling the SPI on page 1443](#) if the CRCEN bit is set.*

Bit 12 **FRXTH**: FIFO reception threshold

This bit is used to set the threshold of the RXFIFO that triggers an RXNE event

0: RXNE event is generated if the FIFO level is greater than or equal to 1/2 (16-bit)

1: RXNE event is generated if the FIFO level is greater than or equal to 1/4 (8-bit)

Bits 11:8 **DS[3:0]**: Data size

These bits configure the data length for SPI transfers.

0000: Not used  
 0001: Not used  
 0010: Not used  
 0011: 4-bit  
 0100: 5-bit  
 0101: 6-bit  
 0110: 7-bit  
 0111: 8-bit  
 1000: 9-bit  
 1001: 10-bit  
 1010: 11-bit  
 1011: 12-bit  
 1100: 13-bit  
 1101: 14-bit  
 1110: 15-bit  
 1111: 16-bit

If software attempts to write one of the “Not used” values, they are forced to the value “0111” (8-bit)

Bit 7 **TXEIE**: Tx buffer empty interrupt enable

0: TXE interrupt masked  
 1: TXE interrupt not masked. Used to generate an interrupt request when the TXE flag is set.

Bit 6 **RXNEIE**: RX buffer not empty interrupt enable

0: RXNE interrupt masked  
 1: RXNE interrupt not masked. Used to generate an interrupt request when the RXNE flag is set.

Bit 5 **ERRIE**: Error interrupt enable

This bit controls the generation of an interrupt when an error condition occurs (CRCERR, OVR, MODF in SPI mode, FRE at TI mode).

0: Error interrupt is masked  
 1: Error interrupt is enabled

Bit 4 **FRF**: Frame format

0: SPI Motorola mode  
 1 SPI TI mode

*Note: This bit must be written only when the SPI is disabled (SPE=0).*

Bit 3 **NSSP**: NSS pulse management

This bit is used in master mode only. it allows the SPI to generate an NSS pulse between two consecutive data when doing continuous transfers. In the case of a single data transfer, it forces the NSS pin high level after the transfer.

It has no meaning if CPHA = '1', or FRF = '1'.

0: No NSS pulse  
 1: NSS pulse generated

*Note: 1. This bit must be written only when the SPI is disabled (SPE=0).*

*2. This bit is not used in SPI TI mode.*

Bit 2 **SSOE**: SS output enable

0: SS output is disabled in master mode and the SPI interface can work in multimaster configuration

1: SS output is enabled in master mode and when the SPI interface is enabled. The SPI interface cannot work in a multimaster environment.

*Note: This bit is not used in SPI TI mode.*

Bit 1 **TXDMAEN**: Tx buffer DMA enable

When this bit is set, a DMA request is generated whenever the TXE flag is set.

0: Tx buffer DMA disabled

1: Tx buffer DMA enabled

Bit 0 **RxDMAEN**: Rx buffer DMA enable

When this bit is set, a DMA request is generated whenever the RXNE flag is set.

0: Rx buffer DMA disabled

1: Rx buffer DMA enabled

### 42.6.3 SPI status register (SPIx\_SR)

Address offset: 0x08

Reset value: 0x0002

| 15   | 14   | 13   | 12         | 11 | 10         | 9 | 8   | 7   | 6   | 5    | 4          | 3    | 2    | 1   | 0    |
|------|------|------|------------|----|------------|---|-----|-----|-----|------|------------|------|------|-----|------|
| Res. | Res. | Res. | FTLVL[1:0] |    | FRLVL[1:0] |   | FRE | BSY | OVR | MODF | CRCE<br>RR | Res. | Res. | TXE | RXNE |
|      |      |      | r          | r  | r          | r | r   | r   | r   | r    | rc_w0      |      |      | r   | r    |

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:11 **FTLVL[1:0]**: FIFO transmission level

These bits are set and cleared by hardware.

00: FIFO empty

01: 1/4 FIFO

10: 1/2 FIFO

11: FIFO full (considered as FULL when the FIFO threshold is greater than 1/2)

Bits 10:9 **FRLVL[1:0]**: FIFO reception level

These bits are set and cleared by hardware.

00: FIFO empty

01: 1/4 FIFO

10: 1/2 FIFO

11: FIFO full

*Note: These bits are not used in SPI receive-only mode while CRC calculation is enabled.*

Bit 8 **FRE**: Frame format error

This flag is used for SPI in TI slave mode. Refer to [Section 42.4.11: SPI error flags](#).

This flag is set by hardware and reset when SPIx\_SR is read by software.

0: No frame format error

1: A frame format error occurred

Bit 7 **BSY**: Busy flag

0: SPI not busy

1: SPI is busy in communication or Tx buffer is not empty

This flag is set and cleared by hardware.

*Note: The BSY flag must be used with caution: refer to [Section 42.4.10: SPI status flags and Procedure for disabling the SPI on page 1443](#).*

Bit 6 **OVR**: Overrun flag

0: No overrun occurred

1: Overrun occurred

This flag is set by hardware and reset by a software sequence.

Bit 5 **MODF**: Mode fault

0: No mode fault occurred

1: Mode fault occurred

This flag is set by hardware and reset by a software sequence. Refer to [Section : Mode fault \(MODF\) on page 1453](#) for the software sequence.

Bit 4 **CRCERR**: CRC error flag

0: CRC value received matches the SPIx\_RXCRCR value

1: CRC value received does not match the SPIx\_RXCRCR value

*Note: This flag is set by hardware and cleared by software writing 0.*

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **TXE**: Transmit buffer empty

0: Tx buffer not empty

1: Tx buffer empty

Bit 0 **RXNE**: Receive buffer not empty

0: Rx buffer empty

1: Rx buffer not empty

#### 42.6.4 SPI data register (SPIx\_DR)

Address offset: 0x0C

Reset value: 0x0000

|          |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|----------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| 15       | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
| DR[15:0] |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
| r/w      | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w |

Bits 15:0 **DR[15:0]**: Data register

Data received or to be transmitted

The data register serves as an interface between the Rx and Tx FIFOs. When the data register is read, RxFIFO is accessed while the write to data register accesses TxFIFO (See [Section 42.4.9: Data transmission and reception procedures](#)).

*Note: Data is always right-aligned. Unused bits are ignored when writing to the register, and read as zero when the register is read. The Rx threshold setting must always correspond with the read access currently used.*

## 42.6.5 SPI CRC polynomial register (SPIx\_CRCPR)

Address offset: 0x10

Reset value: 0x0007

|               |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|---------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 15            | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| CRCPOLY[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw            | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 15:0 **CRCPOLY[15:0]**: CRC polynomial register

This register contains the polynomial for the CRC calculation.

The CRC polynomial (0x0007) is the reset value of this register. Another polynomial can be configured as required.

*Note: The polynomial value should be odd only. No even value is supported.*

## 42.6.6 SPI Rx CRC register (SPIx\_RXCRCR)

Address offset: 0x14

Reset value: 0x0000

|             |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|-------------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 15          | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| RXCRC[15:0] |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| r           | r  | r  | r  | r  | r  | r | r | r | r | r | r | r | r | r | r |

Bits 15:0 **RXCRC[15:0]**: Rx CRC register

When CRC calculation is enabled, the RXCRC[15:0] bits contain the computed CRC value of the subsequently received bytes. This register is reset when the CRCEN bit in SPIx\_CR1 register is written to 1. The CRC is calculated serially using the polynomial programmed in the SPIx\_CRCPR register.

Only the 8 LSB bits are considered when the CRC frame format is set to be 8-bit length (CRCL bit in the SPIx\_CR1 is cleared). CRC calculation is done based on any CRC8 standard.

The entire 16-bits of this register are considered when a 16-bit CRC frame format is selected (CRCL bit in the SPIx\_CR1 register is set). CRC calculation is done based on any CRC16 standard.

*A read to this register when the BSY Flag is set could return an incorrect value.*

## 42.6.7 SPI Tx CRC register (SPIx\_TXCRCR)

Address offset: 0x18

Reset value: 0x0000

|             |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|-------------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 15          | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| TXCRC[15:0] |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| r           | r  | r  | r  | r  | r  | r | r | r | r | r | r | r | r | r | r |

Bits 15:0 **TXCRC[15:0]**: Tx CRC register

When CRC calculation is enabled, the TXCRC[7:0] bits contain the computed CRC value of the subsequently transmitted bytes. This register is reset when the CRCEN bit of SPIx\_CR1 is written to 1. The CRC is calculated serially using the polynomial programmed in the SPIx\_CRCPR register.

Only the 8 LSB bits are considered when the CRC frame format is set to be 8-bit length (CRCL bit in the SPIx\_CR1 is cleared). CRC calculation is done based on any CRC8 standard.

The entire 16-bits of this register are considered when a 16-bit CRC frame format is selected (CRCL bit in the SPIx\_CR1 register is set). CRC calculation is done based on any CRC16 standard.

*A read to this register when the BSY flag is set could return an incorrect value.*

## 42.6.8 SPI register map

[Table 266](#) shows the SPI register map and reset values.

**Table 266. SPI register map and reset values**

| Offset | Register name<br>reset value | 15            | 14      | 13      | 12        | 11      | 10        | 9   | 8   | 7        | 6      | 5        | 4      | 3    | 2    | 1       | 0       |
|--------|------------------------------|---------------|---------|---------|-----------|---------|-----------|-----|-----|----------|--------|----------|--------|------|------|---------|---------|

|        | Reset value                  |               | 0       | 0       | 0         | 0       | 1         | 1   | 1   | 0        | 0      | 0        | 0      | 0    | 0    | 0       | 0       |
| 0x08   | SPIx_SR                      | Res.          | Res.    | Res.    | FTLV[1:0] |         | FRLV[1:0] |     | FRE | BSY      | OVR    | MODF     | CRCERR | Res. | Res. | TXE     | RXNE    |
|        | Reset value                  |               |         |         | 0         | 0       | 0         | 0   | 0   | 0        | 0      | 0        | 0      |      |      | 1       | 0       |
| 0x0C   | SPIx_DR                      | DR[15:0]      |         |         |           |         |           |     |     |          |        |          |        |      |      |         |         |
|        | Reset value                  | 0             | 0       | 0       | 0         | 0       | 0         | 0   | 0   | 0        | 0      | 0        | 0      | 0    | 0    | 0       | 0       |
| 0x10   | SPIx_CRCPDR                  | CRCPOLY[15:0] |         |         |           |         |           |     |     |          |        |          |        |      |      |         |         |
|        | Reset value                  | 0             | 0       | 0       | 0         | 0       | 0         | 0   | 0   | 0        | 0      | 0        | 0      | 0    | 1    | 1       | 1       |
| 0x14   | SPIx_RXCRCR                  | RXCRC[15:0]   |         |         |           |         |           |     |     |          |        |          |        |      |      |         |         |
|        | Reset value                  | 0             | 0       | 0       | 0         | 0       | 0         | 0   | 0   | 0        | 0      | 0        | 0      | 0    | 0    | 0       | 0       |
| 0x18   | SPIx_TXCRCR                  | TXCRC[15:0]   |         |         |           |         |           |     |     |          |        |          |        |      |      |         |         |
|        | Reset value                  | 0             | 0       | 0       | 0         | 0       | 0         | 0   | 0   | 0        | 0      | 0        | 0      | 0    | 0    | 0       | 0       |

Refer to [Section 2.2 on page 75](#) for the register boundary addresses.

## 43 Serial audio interface (SAI)

### 43.1 Introduction

The SAI interface (serial audio interface) offers a wide set of audio protocols due to its flexibility and wide range of configurations. Many stereo or mono audio applications may be targeted. I2S standards, LSB or MSB-justified, PCM/DSP, TDM, and AC'97 protocols may be addressed for example. SPDIF output is offered when the audio block is configured as a transmitter.

To bring this level of flexibility and reconfigurability, the SAI contains two independent audio subblocks. Each block has its own clock generator and I/O line controller.

The SAI works in master or slave configuration. The audio subblocks are either receiver or transmitter and work synchronously or not (with respect to the other one).

The SAI can be connected with other SAIs to work synchronously.

### 43.2 SAI main features

- Two independent audio subblocks, which can be transmitters or receivers with their respective FIFO.
- 8-word integrated FIFOs for each audio subblock.
- Synchronous or asynchronous mode between the audio subblocks.
- Possible synchronization between multiple SAIs.
- Master or slave configuration independent for both audio subblocks.
- Clock generator for each audio block to target independent audio frequency sampling when both audio subblocks are configured in master mode.
- Data size configurable: 8-, 10-, 16-, 20-, 24-, 32-bit.
- Audio protocol: I2S, LSB- or MSB-justified, PCM/DSP, TDM, AC'97
- SPDIF output available if required.
- Up to 16 slots available with configurable size.
- Number of bits by frame can be configurable.
- Frame synchronization active level configurable (offset, bit length, level).
- First active bit position in the slot is configurable.
- LSB first or MSB first for data transfer.
- Mute mode.
- Stereo/Mono audio frame capability.
- Communication clock strobing edge configurable (SCK).
- Error flags with associated interrupts if enabled respectively.
  - Overrun and underrun detection,
  - Anticipated frame synchronization signal detection in slave mode,
  - Late frame synchronization signal detection in slave mode,
  - Codec not ready for the AC'97 mode in reception.
- Interrupt sources when enabled:
  - Errors,

- FIFO requests.
- 2-channel DMA interface.

## 43.3 SAI functional description

### 43.3.1 SAI block diagram

Figure 473 shows the SAI block diagram while Table 267 and Table 268 list SAI internal and external signals.

Figure 473. SAI functional block diagram

The SAI is mainly composed of two audio subblocks with their own clock generator. Each audio block integrates a 32-bit shift register controlled by their own functional state machine. Data are stored or read from the dedicated FIFO. FIFO may be accessed by the CPU, or by DMA to leave the CPU free during the communication. Each audio block is independent. They can be synchronous with each other.

An I/O line controller manages a set of 4 dedicated pins (SD, SCK, FS, MCLK) for a given audio block in the SAI. Some of these pins can be shared if the two subblocks are declared as synchronous to leave some free to be used as general purpose I/Os. The MCLK pin can be output, or not, depending on the application, the decoder requirement and whether the audio block is configured as the master.

If one SAI is configured to operate synchronously with another one, even more I/Os can be freed (except for pins SD\_x).

The functional state machine can be configured to address a wide range of audio protocols. Some registers are present to set up the desired protocols (audio frame waveform generator).

The audio subblock can be a transmitter or receiver, in master or slave mode. The master mode means the SCK\_x bit clock and the frame synchronization signal are generated from the SAI, whereas in slave mode, they come from another external or internal master. There is a particular case for which the FS signal direction is not directly linked to the master or slave mode definition. In AC'97 protocol, it is an SAI output even if the SAI (link controller) is set up to consume the SCK clock (and so to be in Slave mode).

*Note:* For ease of reading of this section, the notation SAI\_x refers to SAI\_A or SAI\_B, where 'x' represents the SAI A or B subblock.

### 43.3.2 SAI pins and internal signals

**Table 267. SAI internal input/output signals**

| Internal signal name                 | Signal type  | Description                                                                              |
|--------------------------------------|--------------|------------------------------------------------------------------------------------------|
| sai_a_gbl_it/<br>sai_b_gbl_it        | Output       | Audio block A and B global interrupts.                                                   |
| sai_a_dma,<br>sai_b_dma              | Input/output | Audio block A and B DMA acknowledges and requests.                                       |
| sai_sync_out_sck,<br>sai_sync_out_fs | Output       | Internal clock and frame synchronization output signals exchanged with other SAI blocks. |
| sai_sync_in_sck,<br>sai_sync_in_fs   | Input        | Internal clock and frame synchronization input signals exchanged with other SAI blocks.  |
| sai_a_ker_ck/<br>sai_b_ker_ck        | Input        | Audio block A/B kernel clock.                                                            |
| sai_pclk                             | Input        | APB clock.                                                                               |

**Table 268. SAI input/output pins**

| Name         | Signal type  | Comments                                        |
|--------------|--------------|-------------------------------------------------|
| SAI_SCK_A/B  | Input/output | Audio block A/B bit clock.                      |
| SAI_MCLK_A/B | Output       | Audio block A/B master clock.                   |
| SAI_SD_A/B   | Input/output | Data line for block A/B.                        |
| SAI_FS_A/B   | Input/output | Frame synchronization line for audio block A/B. |

### 43.3.3 Main SAI modes

Each audio subblock of the SAI can be configured to be master or slave via the MODE bits in the SAI\_xCR1 register of the selected audio block.

#### Master mode

In master mode, the SAI delivers the timing signals to the external connected device:

- The bit clock and the frame synchronization are output on pin SCK\_x and FS\_x, respectively.
- If needed, the SAI can also generate a master clock on the MCLK\_x pin.

Both SCK\_x, FS\_x and MCLK\_x are configured as outputs.

### Slave mode

The SAI expects to receive timing signals from an external device.

- If the SAI subblock is configured in asynchronous mode, then the SCK\_x and FS\_x pins are configured as inputs.
- If the SAI subblock is configured to operate synchronously with another SAI interface or with the second audio subblock, the corresponding SCK\_x and FS\_x pins are left free to be used as general purpose I/Os.

In slave mode, the MCLK\_x pin is not used and can be assigned to another function.

It is recommended to enable the slave device before enabling the master.

### Configuring and enabling SAI modes

Each audio subblock can be independently defined as a transmitter or receiver through the MODE bit in the SAI\_xCR1 register of the corresponding audio block. As a result, the SAI\_SD\_x pin is respectively configured as an output or an input.

Two master audio blocks in the same SAI can be configured with two different MCLK and SCK clock frequencies. In this case, they have to be configured in asynchronous mode.

Each of the audio blocks in the SAI is enabled by the SAIEN bit in the SAI\_xCR1 register. As soon as this bit is active, the transmitter or the receiver is sensitive to the activity on the clock, data, and synchronization lines in slave mode.

In master Tx mode, enabling the audio block immediately generates the bit clock for the external slaves even if there is no data in the FIFO. However, FS signal generation is conditioned by the presence of data in the FIFO. After the FIFO receives the first data to transmit, this data is output to external slaves. If there is no data to transmit in the FIFO, 0 values are then sent in the audio frame with an underrun flag generation.

In slave mode, the audio frame starts when the audio block is enabled and when a start of frame is detected.

In Slave Tx mode, no underrun event is possible on the first frame after the audio block is enabled, because the mandatory operating sequence in this case is:

1. Write into the SAI\_xDR (by software or by DMA).
2. Wait until the FIFO threshold (FLH) flag is different from 0b000 (FIFO empty).
3. Enable the audio block in slave transmitter mode.

## 43.3.4 SAI synchronization mode

There are two levels of synchronization, either at audio subblock level or at SAI level.

### Internal synchronization

An audio subblock can be configured to operate synchronously with the second audio subblock in the same SAI. In this case, the bit clock and the frame synchronization signals are shared to reduce the number of external pins used for the communication. The audio block configured in synchronous mode sees its own SCK\_x, FS\_x, and MCLK\_x pins released back as GPIOs while the audio block configured in asynchronous mode is the one for which FS\_x and SCK\_x and MCLK\_x I/O pins are relevant (if the audio block is considered as master).

Typically, the audio block in synchronous mode can be used to configure the SAI in full duplex mode. One of the two audio blocks can be configured as a master and the other as slave, or both as slaves with one asynchronous block (corresponding SYNCEN[1:0] bits set to 00 in SAI\_xCR1) and one synchronous block (corresponding SYNCEN[1:0] bits set to 01 in the SAI\_xCR1 register).

**Note:** *Due to internal resynchronization stages, PCLK APB frequency must be higher than twice the bit rate clock frequency.*

### External synchronization

The audio subblocks can also be configured to operate synchronously with another SAI. This can be done as follows:

1. The SAI, which is configured as the source from which the other SAI is synchronized, has to define which of its audio subblocks is supposed to provide the FS and SCK signals to other SAI. This is done by programming SYNCOUT[1:0] bits.
2. The SAI which receives the synchronization signals, has to select which SAI provides the synchronization by setting the proper value on SYNCIN[1:0] bits. For each of the two SAI audio subblocks, the user must then specify if it operates synchronously with the other SAI via the SYNCEN bit.

**Note:** *The SYNCIN[1:0] and SYNCOUT[1:0] bits are located in the SAI\_GCR register, and the SYNCEN bits in the SAI\_xCR1 register.*

If both audio subblocks in a given SAI need to be synchronized with another SAI, it is possible to choose one of the following configurations:

- Configure each audio block to be synchronous with another SAI block through the SYNCEN[1:0] bits.
- Configure one audio block to be synchronous with another SAI through the SYNCEN[1:0] bits. The other audio block is then configured as synchronous with the second SAI audio block through SYNCEN[1:0] bits.

The following table shows how to select the proper synchronization signal depending on the SAI block used. For example SAI2 can select the synchronization from SAI1 by setting SAI2 SYNCIN to 0. If SAI1 wants to select the synchronization coming from SAI2, SAI1 SYNCIN must be set to 1. Positions noted as 'Reserved' must not be used.

**Table 269. External synchronization selection**

| Block instance | SYNCIN= 3 | SYNCIN= 2 | SYNCIN= 1  | SYNCIN= 0  |
|----------------|-----------|-----------|------------|------------|
| SAI1           | Reserved  | Reserved  | SAI2 sync. | Reserved   |
| SAI2           | Reserved  | Reserved  | Reserved   | SAI1 sync. |

### 43.3.5 Audio data size

The audio frame can target different data sizes by configuring bit DS[2:0] in the SAI\_xCR1 register. The data sizes may be 8, 10, 16, 20, 24, or 32 bits. During the transfer, either the MSB or the LSB of the data is sent first, depending on the configuration of the LSBFIRST bit in the SAI\_xCR1 register.

### 43.3.6 Frame synchronization

The FS signal acts as the frame synchronization signal in the audio frame (start of frame). The shape of this signal is completely configurable to target the different audio protocols with their own specificities concerning this frame synchronization behavior. This reconfigurability is done using the SAI\_xFRCR register. [Figure 474](#) illustrates this flexibility.

**Figure 474. Audio frame**

In AC'97 mode or in SPDIF mode (bit PRTCFG[1:0] = 10 or PRTCFG[1:0] = 01 in the SAI\_xCR1 register), the frame synchronization shape is forced to match the AC'97 protocol. The SAI\_xFRCR register value is ignored.

Each audio block is independent and consequently each one requires a specific configuration.

#### Frame length

- Master mode

The audio frame length can be configured to up to 256-bit clock cycles, by configuring the FRL[7:0] field in the SAI\_xFRCR register.

If the frame length is greater than the number of declared slots for the frame, the remaining bits to transmit are extended to 0 or the SD line is released to high-Z depending on the state of bit TRIS in the SAI\_xCR2 register (refer to [FS signal role](#)). In reception mode, the remaining bit is ignored.

If bit NODIV is cleared, (FRL+1) must be equal to a power of 2, from 8 to 256, to ensure that an audio frame contains an integer number of MCLK pulses per bit clock cycle.

If bit NODIV is set, the (FRL+1) field can take any value from 8 to 256. Refer to [Section 43.3.8: SAI clock generator](#)

- Slave mode

The audio frame length is mainly used to specify to the slave the number of bit clock cycles per audio frame sent by the external master. It is used mainly to detect from the master any anticipated or late occurrence of the frame synchronization signal during an ongoing audio frame. In this case, an error is generated. For more details, refer to [Section 43.3.13: Error flags](#).

In slave mode, there are no constraints on the FRL[7:0] configuration in the SAI\_xFRCR register.

The number of bits in the frame is equal to FRL[7:0] + 1.

The minimum number of bits to transfer in an audio frame is 8.

### Frame synchronization polarity

The FSPOL bit in the SAI\_xFRCR register sets the active polarity of the FS pin from which a frame is started. The start of the frame is edge sensitive.

In slave mode, the audio block waits for a valid frame to start transmitting or receiving. The start of the frame is synchronized to this signal. It is effective only if the start of the frame is not detected during an ongoing communication and assimilated to an anticipated start of frame (refer to [Section 43.3.13: Error flags](#)).

In master mode, the frame synchronization is sent continuously each time an audio frame is complete until the SAIEN bit in the SAI\_xCR1 register is cleared. If no data are present in the FIFO at the end of the previous audio frame, an underrun condition is managed as described in [Section 43.3.13: Error flags](#), but the audio communication flow is not interrupted.

### Frame synchronization active level length

The FSALL[6:0] bits of the SAI\_xFRCR register enable the configuration of the length of the active level of the frame synchronization signal. The length can be set from 1- to 128-bit clock cycles.

As an example, the active length can be half of the frame length in I2S, LSB or MSB-justified modes, or one-bit wide for PCM/DSP or TDM.

### Frame synchronization offset

Depending on the audio protocol targeted in the application, the frame synchronization signal can be asserted when transmitting the last bit or the first bit of the audio frame (this is the case in I2S standard protocol and in MSB-justified protocol, respectively). The FSOFF bit in the SAI\_xFRCR register enables the possibility to choose between two configurations.

### FS signal role

The FS signal can have a different meaning depending on the FS function. FSDEF bit in the SAI\_xFRCR register selects which meaning it has:

- 0: start of frame, like, for instance, the PCM/DSP, TDM, AC'97, audio protocols,
- 1: start of frame and channel side identification within the audio frame like for the I2S or the MSB- or LSB-justified protocols.

When the FS signal is considered as a start of frame and channel side identification within the frame, the number of declared slots must be considered to be half the number for the left channel and half the number for the right channel. If the number of bit clock cycles on half audio frame is greater than the number of slots dedicated to a channel side, and TRIS = 0, 0 is sent for transmission for the remaining bit clock cycles in the SAI\_xCR2 register. Otherwise, if TRIS = 1, the SD line is released to high-Z. In reception mode, the remaining bit clock cycles are not considered until the channel side changes.

**Figure 475. FS role is start of frame + channel side identification (FSDEF = TRIS = 1)**

1. The frame length must be even.

If the FSDEF bit in SAI\_xFRCR is kept clear, so FS signal is equivalent to a start of frame, and if the number of slots defined in NBSLOT[3:0] in SAI\_xSLOTR multiplied by the number of bits by slot configured in SLOTSZ[1:0] in SAI\_xSLOTR is less than the frame size (bit FRL[7:0] in the SAI\_xFRCR register), then:

- If TRIS = 0 in the SAI\_xCR2 register, the remaining bit after the last slot is forced to 0 until the end of frame in case of transmitter,
- If TRIS = 1, the line is released to high-Z during the transfer of these remaining bits. In reception mode, these bits are discarded.

Figure 476. FS role is start of frame (FSDEF = 0)

The FS signal is not used when the audio block in transmitter mode is configured to get the SPDIF output on the SD line. The corresponding FS I/O is released and left free for other purposes.

### 43.3.7 Slot configuration

The slot is the basic element in the audio frame. The number of slots in the audio frame is equal to  $\text{NBSLOT}[3:0] + 1$ .

The maximum number of slots per audio frame is fixed at 16.

For AC'97 protocol or SPDIF (when bit  $\text{PRTCFCFG}[1:0] = 10$  or  $\text{PRTCFCFG}[1:0] = 01$ ), the number of slots is automatically set to target the protocol specification, and the value of  $\text{NBSLOT}[3:0]$  is ignored.

Each slot can be defined as a valid slot, or not, by setting  $\text{SLOTEN}[15:0]$  bits of the  $\text{SAI\_xSLOTR}$  register.

When an invalid slot is transferred, the SD data line is either forced to 0 or released to high-Z depending on the TRIS bit configuration (refer to [Output data line management on an inactive slot](#)) in transmitter mode. In receiver mode, the received value from the end of this slot is ignored. Consequently, there is no FIFO access and so no request to read or write the FIFO linked to this inactive slot status.

The slot size is also configurable as shown in [Figure 477](#). The size of the slots is selected by configuring the  $\text{SLOTSZ}[1:0]$  bits in the  $\text{SAI\_xSLOTR}$  register. The size is applied identically for each slot in an audio frame.

**Figure 477. Slot size configuration with FBOFF = 0 in SAI\_xSLOTR**

It is possible to choose the position of the first data bit to transfer within the slots. This offset is configured by FBOFF[4:0] bits in the SAI\_xSLOTR register. 0 values are injected in transmitter mode from the beginning of the slot until this offset position is reached. In reception, the bit in the offset phase is ignored. This feature targets the LSB justified protocol (if the offset is equal to the slot size minus the data size).

**Figure 478. First bit offset**

It is mandatory to respect the following conditions to avoid bad SAI behavior:

$$\text{FBOFF} \leq (\text{SLOTSZ} - \text{DS}),$$

$$\text{DS} \leq \text{SLOTSZ},$$

$$\text{NBSLOT} \times \text{SLOTSZ} \leq \text{FRL (frame length)},$$

The number of slots must be even when bit FSDEF in the SAI\_xFRCR register is set.

In AC'97 and SPDIF protocol (bit PRTCFG[1:0] = 10 or PRTCFG[1:0] = 01), the slot size is automatically set as defined in [Section 43.3.10: AC'97 link controller](#).

### 43.3.8 SAI clock generator

Each audio block has its own clock generator that makes these two blocks completely independent. There is no difference in terms of functionality between these two clock generators.

When the audio block is configured as Master, the clock generator provides the communication clock (the bit clock) and the master clock for external decoders.

When the audio block is defined as slave, the clock generator is OFF.

Figure 479 illustrates the architecture of the audio block clock generator.

**Figure 479. Audio block clock generator overview**

**Note:** If *NODIV* is set to 1, the *MCLK\_x* signal is set at 0 level if this pin is configured as the SAI pin in GPIO peripherals.

The clock source for the clock generator comes from the product clock controller. The *sai\_x\_ker\_ck* clock is equivalent to the master clock, which can be divided for the external decoders using bit *MCKDIV[3:0]*:

$MCLK\_x = sai\_x\_ker\_ck / (MCKDIV[3:0] * 2)$ , if *MCKDIV[3:0]* is not equal to 0000.

$MCLK\_x = sai\_x\_ker\_ck$ , if *MCKDIV[3:0]* is equal to 0000.

*MCLK\_x* signal is used only in Free protocol mode.

The division must be even to keep 50% on the duty cycle on the *MCLK* output and on the *SCK\_x* clock. If bit *MCKDIV[3:0]* = 0000, division by one is applied to obtain *MCLK\_x* equal to *sai\_x\_ker\_ck*.

In the SAI, the single ratio *MCLK/FS* = 256 is considered. Mostly, three frequency ranges are encountered, as illustrated in Table 270.

Table 270. Example of possible audio frequency sampling range

| Input sai_x_ker_ck clock frequency | Most usual audio frequency sampling achievable | MCKDIV[3:0]        |
|------------------------------------|------------------------------------------------|--------------------|
| 192 kHz x 256                      | 192 kHz                                        | MCKDIV[3:0] = 0000 |
|                                    | 96 kHz                                         | MCKDIV[3:0] = 0001 |
|                                    | 48 kHz                                         | MCKDIV[3:0] = 0010 |
|                                    | 16 kHz                                         | MCKDIV[3:0] = 0110 |
|                                    | 8 kHz                                          | MCKDIV[3:0] = 1100 |
| 44.1 kHz x 256                     | 44.1 kHz                                       | MCKDIV[3:0] = 0000 |
|                                    | 22.05 kHz                                      | MCKDIV[3:0] = 0001 |
|                                    | 11.025 kHz                                     | MCKDIV[3:0] = 0010 |
| sai_x_ker_ck = MCLK <sup>(1)</sup> | MCLK                                           | MCKDIV[3:0] = 0000 |

1. This may happen when the product clock controller selects an external clock source, instead of PLL clock.

The master clock can be generated externally on an I/O pad for external decoders if the corresponding audio block is declared as master with bit NODIV = 0 in the SAI\_xCR1 register. In slave, the value set in this last bit is ignored since the clock generator is OFF, and the MCLK\_x I/O pin is released for use as a general purpose I/O.

The bit clock is derived from the master clock. The bit clock divider sets the divider factor between the bit clock (SCK\_x) and the master clock (MCLK\_x) following the formula:

$$SCK\_x = MCLK \times (FRL[7:0] + 1) / 256$$

Where:

256 is the fixed ratio between MCLK and the audio frequency sampling.

FRL[7:0] is the number of bit clock cycles- 1 in the audio frame, configured in the SAI\_xFRCR register.

In master mode, it is mandatory that (FRL[7:0] + 1) is equal to a number with a power of 2 (refer to [Section 43.3.6: Frame synchronization](#)) to obtain an even integer number of MCLK\_x pulses by bit clock cycle. The 50% duty cycle is guaranteed on the bit clock (SCK\_x).

The sai\_x\_ker\_ck clock can also be equal to the bit clock frequency. In this case, the NODIV bit in the SAI\_xCR1 register should be set and the value inside the MCKDIV divider and the bit clock divider will be ignored. In this case, the number of bits per frame is fully configurable without the need to be equal to a power of two.

The bit clock strobing edge on SCK can be configured by bit CKSTR in the SAI\_xCR1 register.

Refer to [Section 43.3.11: SPDIF output](#) for details on clock generator programming in SPDIF mode.

### 43.3.9 Internal FIFOs

Each audio block in the SAI has its own FIFO. Depending on if the block is defined to be a transmitter or a receiver, the FIFO can be written or read, respectively. Thus, there is only one FIFO request linked to the **FREQ** bit in the **SAI\_xSR** register.

An interrupt is generated if the **FREQIE** bit is enabled in the **SAI\_xIM** register. This depends on:

- The FIFO threshold setting (**FLVL** bits in **SAI\_xCR2**).
- Communication direction (transmitter or receiver). Refer to [Interrupt generation in transmitter mode](#) and [Interrupt generation in reception mode](#).

#### Interrupt generation in transmitter mode

The interrupt generation depends on the FIFO configuration in transmitter mode:

- When the FIFO threshold bits in the **SAI\_xCR2** register are configured as FIFO empty (**FTH**[2:0] set to 0b000), an interrupt is generated (**FREQ** bit set by hardware to 1 in the **SAI\_xSR** register) if no data are available in the **SAI\_xDR** register (**FLVL**[2:0] bits in **SAI\_xSR** are less than 0b001). This interrupt (**FREQ** bit in the **SAI\_xSR** register) is cleared by hardware when the FIFO is no longer empty (**FLVL**[2:0] bits in **SAI\_xSR** are different from 0b000), that is, one or more data are stored in the FIFO.
- When the FIFO threshold bits in the **SAI\_xCR2** register are configured as FIFO quarter full (**FTH**[2:0] set to 0b001), an interrupt is generated (**FREQ** bit set by hardware to 1 in the **SAI\_xSR** register) if less than a quarter of the FIFO contains data (**FLVL**[2:0] bits in **SAI\_xSR** are less than 0b010). This interrupt (**FREQ** bit in the **SAI\_xSR** register) is cleared by hardware when at least a quarter of the FIFO contains data (**FLVL**[2:0] bits in **SAI\_xSR** are higher than or equal to 0b010).
- When the FIFO threshold bits in the **SAI\_xCR2** register are configured as FIFO half full (**FTH**[2:0] set to 0b010), an interrupt is generated (**FREQ** bit set by hardware to 1 in the **SAI\_xSR** register) if less than half of the FIFO contains data (**FLVL**[2:0] bits in **SAI\_xSR** are less than 0b011). This interrupt (**FREQ** bit in the **SAI\_xSR** register) is cleared by hardware when at least half of the FIFO contains data (**FLVL**[2:0] bits in **SAI\_xSR** are higher than or equal to 0b011).
- When the FIFO threshold bits in the **SAI\_xCR2** register are configured as FIFO three quarter (**FTH**[2:0] set to 0b011), an interrupt is generated (**FREQ** bit is set by hardware to 1 in the **SAI\_xSR** register) if less than three quarters of the FIFO contains data (**FLVL**[2:0] bits in **SAI\_xSR** are less than 0b100). This interrupt (**FREQ** bit in the **SAI\_xSR** register) is cleared by hardware when at least three quarters of the FIFO contains data (**FLVL**[2:0] bits in **SAI\_xSR** are higher than or equal to 0b100).
- When the FIFO threshold bits in the **SAI\_xCR2** register are configured as FIFO full (**FTH**[2:0] set to 0b100), an interrupt is generated (**FREQ** bit is set by hardware to 1 in the **SAI\_xSR** register) if the FIFO is not full (**FLVL**[2:0] bits in **SAI\_xSR** are less than 0b101). This interrupt (**FREQ** bit in the **SAI\_xSR** register) is cleared by hardware when the FIFO is full (**FLVL**[2:0] bits in **SAI\_xSR** are equal to 0b101).

#### Interrupt generation in reception mode

The interrupt generation depends on the FIFO configuration in reception mode:

- When the FIFO threshold bits in the **SAI\_xCR2** register are configured as FIFO empty (**FTH**[2:0] set to 0b000), an interrupt is generated (**FREQ** bit is set by hardware to 1 in the **SAI\_xSR** register) if at least one data is available in the **SAI\_xDR** register (**FLVL**[2:0] bits

in SAI\_xSR are higher than or equal to 0b001). This interrupt (FREQ bit in the SAI\_xSR register) is cleared by hardware when the FIFO becomes empty (FLVL[2:0] bits in the SAI\_xSR are equal to 0b000), that is, no data are stored in FIFO.

- When the FIFO threshold bits in the SAI\_xCR2 register are configured as FIFO quarter full (FTH[2:0] set to 0b001), an interrupt is generated (FREQ bit is set by hardware to 1 in the SAI\_xSR register) if at least one quarter of the FIFO data locations are available (FLVL[2:0] bits in SAI\_xSR are higher than or equal to 0b010). This interrupt (FREQ bit in the SAI\_xSR register) is cleared by hardware when less than a quarter of the FIFO data locations become available (FLVL[2:0] bits in SAI\_xSR are less than 0b010).
- When the FIFO threshold bits in the SAI\_xCR2 register are configured as FIFO half full (FTH[2:0] set to 0b010), an interrupt is generated (FREQ bit is set by hardware to 1 in the SAI\_xSR register) if at least half of the FIFO data locations are available (FLVL[2:0] bits in SAI\_xSR are higher than or equal to 0b011). This interrupt (FREQ bit in the SAI\_xSR register) is cleared by hardware when less than half of the FIFO data locations become available (FLVL[2:0] bits in SAI\_xSR are less than 0b011).
- When the FIFO threshold bits in the SAI\_xCR2 register are configured as FIFO three quarter full (FTH[2:0] set to 0b011), an interrupt is generated (FREQ bit is set by hardware to 1 in the SAI\_xSR register) if at least three quarters of the FIFO data locations are available (FLVL[2:0] bits in SAI\_xSR are higher than or equal to 0b100). This interrupt (FREQ bit in the SAI\_xSR register) is cleared by hardware when the FIFO has less than three quarters of the FIFO data locations available (FLVL[2:0] bits in SAI\_xSR is less than 0b100).
- When the FIFO threshold bits in the SAI\_xCR2 register are configured as FIFO full (FTH[2:0] set to 0b100), an interrupt is generated (FREQ bit is set by hardware to 1 in the SAI\_xSR register) if the FIFO is full (FLVL[2:0] bits in SAI\_xSR are equal to 0b101). This interrupt (FREQ bit in the SAI\_xSR register) is cleared by hardware when the FIFO is not full (FLVL[2:0] bits in SAI\_xSR are less than 0b101).

Like interrupt generation, the SAI can use the DMA if the DMAEN bit in the SAI\_xCR1 register is set. The FREQ bit assertion mechanism is the same as the interrupt generation mechanism described above for FREQIE.

Each FIFO is an 8-word FIFO. Each read or write operation from/to the FIFO targets one word FIFO location whatever the access size. Each FIFO word contains one audio slot. FIFO pointers are incremented by one word after each access to the SAI\_xDR register.

Data must be right-aligned when written in the SAI\_xDR register.

Data received are right-aligned in the SAI\_xDR register.

The FIFO pointers can be reinitialized when the SAI is disabled by configuring the FFLUSH bit in the SAI\_xCR2 register. If FFLUSH is set when the SAI is enabled, the data present in the FIFO are lost automatically.

### 43.3.10 AC'97 link controller

The SAI is able to work as an AC'97 link controller. In this protocol:

- The slot number and the slot size are fixed.
- The frame synchronization signal is perfectly defined and has a fixed shape.

To select this protocol, set the PRTCFG[1:0] bits in the SAI\_xCR1 register to 10. When AC'97 mode is selected, only data sizes of 16 or 20 bits can be used, otherwise the SAI behavior is not guaranteed.

- The NBSLOT[3:0] and SLOTSZ[1:0] bits are consequently ignored.
- The number of slots is fixed at 13 slots. The first one is 16 bits wide and all the others are 20 bits wide (data slots).
- The FBOFF[4:0] bits in the SAI\_xSLOTR register are ignored.
- The SAI\_xFRCR register is ignored.
- The MCLK is not used.

The FS signal from the block defined as asynchronous is configured automatically as an output, since the AC'97 controller link drives the FS signal whatever the master or slave configuration.

Figure 480 shows an AC'97 audio frame structure.

**Figure 480. AC'97 audio frame**

**Note:** In the AC'97 protocol, bit 2 of the tag is reserved (always 0), so bit 2 of the TAG is forced to 0 level whatever the value written in the SAI FIFO.

For more details about tag representation, refer to the AC'97 protocol standard.

One SAI can be used to target an AC'97 point-to-point communication.

Using two SAIs (for devices featuring two embedded SAIs) enables the control of three external AC'97 decoders as illustrated in Figure 481.

In SAI1, the audio block A must be declared as asynchronous master transmitter, whereas the audio block B is defined to be slave receiver and internally synchronous to the audio block A.

The SAI2 is configured for audio block A and B both synchronous with the external SAI1 in slave receiver mode.

**Figure 481. Example of typical AC'97 configuration on devices featuring at least 2 embedded SAIs (three external AC'97 decoders)**

In receiver mode, the SAI acting as an AC'97 link controller requires no FIFO request and so no data storage in the FIFO when the codec-ready bit in slot 0 is decoded low. If bit CNRDYIE is enabled in the SAI\_xIM register, flag CNRDY is set in the SAI\_xSR register and an interrupt is generated. This flag is dedicated to the AC'97 protocol.

### Clock generator programming in AC'97 mode

In AC'97 mode, the frame length is fixed at 256 bits, and its frequency must be set to 48 kHz. The formulas given in [Section 43.3.8: SAI clock generator](#) must be used with  $FRL = 255$ , to generate the proper frame rate ( $F_{FS\_x}$ ).

### 43.3.11 SPDIF output

The SPDIF interface is available in transmitter mode only. It supports the audio IEC60958.

To select SPDIF mode, set the PRTCFG[1:0] bits to 01 in the SAI\_xCR1 register.

For SPDIF protocol:

- Only the SD data line is enabled.
- The FS, SCK, and MCLK I/Os pins are left free.
- The MODE[1] bit is forced to 0 to select the master mode to enable the clock generator of the SAI and manage the data rate on the SD line.
- The data size is forced to 24 bits. The value set in the DS[2:0] bits in the SAI\_xCR1 register is ignored.
- The clock generator must be configured to define the symbol-rate, knowing that the bit clock must be twice the symbol-rate. The data is coded in Manchester protocol.
- The SAI\_xFRCR and SAI\_xSLOTR registers are ignored. The SAI is configured internally to match the SPDIF protocol requirements as shown in [Figure 482](#).

**Figure 482. SPDIF format**

An SPDIF block contains 192 frames. Each frame is composed of two 32-bit subframes, generally one for the left channel and one for the right channel. Each subframe is composed of a SOPD pattern (4-bit) to specify if the subframe is the start of a block (and so is identifying a channel A) or if it is identifying a channel A somewhere in the block, or if it is referring to channel B (see [Table 271](#)). The next 28 bits of channel information are composed of 24 data bits + 4 status bits.

Table 271. SOPD pattern

| SOPD | Preamble coding |               | Description                           |
|------|-----------------|---------------|---------------------------------------|
|      | last bit is 0   | last bit is 1 |                                       |
| B    | 11101000        | 00010111      | Channel A data at the start of block  |
| W    | 11100100        | 00011011      | Channel B data somewhere in the block |
| M    | 11100010        | 00011101      | Channel A data                        |

The data stored in SAI\_xDR has to be filled as follows:

- SAI\_xDR[26:24] contain the channel status, user, and validity bits.
- SAI\_xDR[23:0] contain the 24-bit data for the considered channel.

If the data size is 20 bits, the data must be mapped on SAI\_xDR[23:4].

If the data size is 16 bits, the data must be mapped on SAI\_xDR[23:8].

SAI\_xDR[23] always represents the MSB.

Figure 483. SAI\_xDR register ordering

**Note:** The transfer is always performed with LSB first.

The SAI first sends the adequate preamble for each subframe in a block. The SAI\_xDR is then sent on the SD line (Manchester coded). The SAI ends the subframe by transferring the parity bit calculated as described in [Table 272](#).

Table 272. Parity bit calculation

| SAI_xDR[26:0]   | Parity bit P value transferred |
|-----------------|--------------------------------|
| odd number of 0 | 0                              |
| odd number of 1 | 1                              |

The underrun is the only error flag available in the SAI\_xSR register for SPDIF mode since the SAI can only operate in transmitter mode. As a result, the following sequence must be

executed to recover from an underrun error detected via the underrun interrupt or the underrun status bit:

1. Disable the DMA stream (via the DMA peripheral) if the DMA is used.
2. Disable the SAI and check that the peripheral is physically disabled by polling the SAIEN bit in the SAI\_xCR1 register.
3. Clear the COVRUNDR flag in the SAI\_xCLRFR register.
4. Flush the FIFO by setting the FFLUSH bit in SAI\_xCR2.  
The software needs to point to the address of the future data corresponding to the start of a new block (data for preamble B). If the DMA is used, the DMA source base address pointer must be updated accordingly.
5. Enable the DMA stream (DMA peripheral) again if the DMA is used to manage data transfers according to the new source base address.
6. Enable the SAI again by configuring the SAIEN bit in the SAI\_xCR1 register.

### Clock generator programming in SPDIF generator mode

For the SPDIF generator, the SAI provides a bit clock twice as fast as the symbol-rate. The table below shows examples of symbol rates with respect to the audio sampling rate.

**Table 273. Audio sampling frequency versus symbol rates**

| Audio sampling frequencies (F <sub>S</sub> ) | Symbol-rate |
|----------------------------------------------|-------------|
| 44.1 kHz                                     | 2.8224 MHz  |
| 48 kHz                                       | 3.072 MHz   |
| 96 kHz                                       | 6.144 MHz   |
| 192 kHz                                      | 12.288 MHz  |

More generally, the relationship between the audio sampling frequency (F<sub>S</sub>) and the bit clock rate (F<sub>SCK\_x</sub>) is given by the formula:

$$F_S = \frac{F_{SCK\_x}}{128}$$

The bit clock rate is obtained as follows:

$$F_{SCK\_x} = F_{sai\_x\_ker\_ck}$$

*Note:* The above formulas are valid only if NODIV is set to 1 in the SAI\_ACR1 register.

### 43.3.12 Specific features

The SAI interface embeds specific features that can be useful depending on the audio protocol selected. These functions are accessible through specific bits of the SAI\_xCR2 register.

#### Mute mode

The mute mode can be used when the audio subblock is a transmitter or a receiver.

##### Audio subblock in transmission mode

In transmitter mode, the mute mode can be selected at any time. The mute mode is active for entire audio frames. The MUTE bit in the SAI\_xCR2 register enables the mute mode when it is configured during an ongoing frame.

The mute mode bit is strobed only at the end of the frame. If it is set at this time, the mute mode is active at the beginning of the new audio frame and for a complete frame, until the next end of frame. The bit is then strobed to determine if the next frame is still a mute frame.

If the number of slots set through the NBSLOT[3:0] bits in the SAI\_xSLOTR register is lower than or equal to 2, it is possible to specify if the value sent in mute mode is 0 or if it is the last value of each slot. The selection is done via the MUTEVAL bit in the SAI\_xCR2 register.

If the number of slots set in the NBSLOT[3:0] bits in the SAI\_xSLOTR register is greater than 2, the MUTEVAL bit in the SAI\_xCR2 register is meaningless as 0 values are sent on each bit on each slot.

The FIFO pointers are still incremented in mute mode. This means that data present in the FIFO and for which the mute mode is requested are discarded.

##### Audio subblock in reception mode

In reception mode, it is possible to detect a mute mode sent from the external transmitter when all the declared and valid slots of the audio frame receive 0 for a given consecutive number of audio frames (MUTECNT[5:0] bits in the SAI\_xCR2 register).

When the number of MUTE frames is detected, the MUTEDET flag in the SAI\_xSR register is set and an interrupt can be generated if the MUTEDETIE bit is set in SAI\_xCR2.

The mute frame counter is cleared when the audio subblock is disabled or when a valid slot receives at least one data in an audio frame. The interrupt is generated just once, when the counter reaches the value specified in the MUTECNT[5:0] bits. The interrupt event is then reinitialized when the counter is cleared.

*Note:* The mute mode is not available for SPDIF audio blocks.

#### Mono/stereo mode

In transmitter mode, the mono mode can be addressed without any data preprocessing in memory, assuming the number of slots is equal to 2 (NBSLOT[3:0] = 0001 in SAI\_xSLOTR). In this case, the access time to and from the FIFO is reduced by 2 since the data for slot 0 is duplicated into data slot 1.

To enable the mono mode:

1. Set the MONO bit to 1 in the SAI\_xCR1 register.
2. Set NBSLOT to 1 and SLOTEN to 3 in SAI\_xSLOTR.

In reception mode, the MONO bit can be set and is meaningful only if the number of slots is equal to 2, like in transmitter mode. When it is set, only slot 0 data are stored in the FIFO. The data belonging to slot 1 are discarded since, in this case, it is supposed to be the same as the previous slot. If the data flow in reception mode is a real stereo audio flow with a distinct and different left and right data, the MONO bit is meaningless. The conversion from the output stereo file to the equivalent mono file is done by software.

### Companding mode

Telecommunication applications can require processing the data to be transmitted or received using a data companding algorithm.

Depending on the COMP[1:0] bits in the SAI\_xCR2 register (used only when free protocol mode is selected), the application software can choose to process or not the data before sending it on the SD serial output line (compression) or to expand the data after the reception on the SD serial input line (expansion), as illustrated in [Figure 484](#). The two companding modes supported are the  $\mu$ -Law and the A-Law logs, which are a part of the CCITT G.711 recommendation.

The companding standard used in the United States and Japan is the  $\mu$ -Law. It supports 14 bits of dynamic range (COMP[1:0] = 10 in the SAI\_xCR2 register).

The European companding standard is A-Law and supports 13 bits of dynamic range (COMP[1:0] = 11 in the SAI\_xCR2 register).

Both  $\mu$ -Law and A-Law companding standard can be computed based on 1's complement or 2's complement representation, depending on the CPL bit setting in the SAI\_xCR2 register.

In  $\mu$ -Law and A-Law standards, data are coded as 8 bits with MSB alignment. Companded data are always 8 bits wide. For this reason, the DS[2:0] bits in the SAI\_xCR1 register are forced to 010 when the SAI audio block is enabled (the SAIEN bit = 1 in the SAI\_xCR1 register) and when one of these two companding modes is selected through the COMP[1:0] bits.

If no companding processing is required, the COMP[1:0] bits must be kept clear.

**Figure 484. Data companding hardware in an audio block in the SAI**

1. Not applicable when AC'97 or SPDIF are selected.

Expansion and compression mode are automatically selected through SAI\_xCR2:

- If the SAI audio block is configured to be a transmitter, and if the COMP[1] bit is set in the SAI\_xCR2 register, the compression mode is applied.
- If the SAI audio block is declared as a receiver, the expansion algorithm is applied.

### Output data line management on an inactive slot

In transmitter mode, it is possible to choose the behavior of the SD line output when an inactive slot is sent on the data line (via the TRIS bit).

- Either the SAI forces 0 on the SD output line when an inactive slot is transmitted, or
- The line is released in high-Z state at the end of the last bit of data transferred, to release the line for other transmitters connected to this node.

It is important to note that the two transmitters cannot attempt to drive the same SD output pin simultaneously, which may result in a short circuit. To ensure a gap between transmissions, if the data is lower than 32-bit, the data can be extended to 32-bit by setting the bit SLOTSZ[1:0] = 10 in the SAI\_xSLOTR register. The SD output pin is then tri-stated at the end of the LSB of the active slot (during the padding to 0 phase to extend the data to 32-bit) if the following slot is declared inactive.

In addition, if the number of slots multiplied by the slot size is lower than the frame length, the SD output line is tri-stated when the padding to 0 is done to complete the audio frame.

*Figure 485* illustrates these behaviors.

**Figure 485. Tristate strategy on SD output line on an inactive slot**

When the selected audio protocol uses the FS signal as a start of frame and a channel side identification (bit FSDEF = 1 in the SAI\_xFRCR register), the tristate mode is managed according to [Figure 486](#) (where the bit TRIS in the SAI\_xCR1 register = 1, and FSDEF=1, and half frame length is higher than number of slots/2, and NBSLOT=6).

**Figure 486. Tristate on output data line in a protocol like I2S**

If the TRIS bit in the SAI\_xCR2 register is cleared, all the high impedance states on the SD output line in [Figure 485](#) and [Figure 486](#) are replaced by a drive with a value of 0.

### 43.3.13 Error flags

The SAI implements the following error flags:

- FIFO overrun/underrun.
- Anticipated frame synchronization detection.
- Late frame synchronization detection.
- Codec not ready (AC'97 exclusively).
- Wrong clock configuration in master mode.

#### FIFO overrun/underrun (OVRUDR)

The FIFO overrun/underrun bit is called OVRUDR in the SAI\_xSR register.

The overrun or underrun errors share the same bit since an audio block can be either receiver or transmitter and each audio block in a given SAI has its own SAI\_xSR register.

#### Overrun

When the audio block is configured as receiver, an overrun condition may appear if data are received in an audio frame when the FIFO is full and not able to store the received data. In this case, the received data are lost, the OVRUDR flag in the SAI\_xSR register is set, and an interrupt is generated if the OVRUDRIE bit is set in the SAI\_xIM register. The slot number, from which the overrun occurs, is stored internally. No more data are stored into the FIFO until it becomes free to store new data. When the FIFO has at least one data free, the SAI audio block receiver stores new data (from a new audio frame) from the slot number that was stored internally when the overrun condition was detected. This avoids data slot dealignment in the destination memory (refer to [Figure 487](#)).

The OVRUDR flag is cleared when the COVRUDR bit is set in the SAI\_xCLRFR register.

Figure 487. Overrun detection error

### Underrun

An underrun may occur when the audio block in the SAI is a transmitter and the FIFO is empty when data need to be transmitted. If an underrun is detected, the slot number for which the event occurs is stored and the MUTE value (00) is sent until the FIFO is ready to transmit the data corresponding to the slot for which the underrun was detected (refer to [Figure 488](#)). This avoids desynchronization between the memory pointer and the slot in the audio frame.

The underrun event sets the OVRUDR flag in the SAI\_xSR register and an interrupt is generated if the OVRUDRIE bit is set in the SAI\_xIM register. To clear this flag, set the COVRUDR bit in the SAI\_xCLRFR register.

The underrun event can occur when the audio subblock is configured as master or slave.

Figure 488. FIFO underrun event

### Anticipated frame synchronization detection (AFSDET)

The AFSDET flag is used only in slave mode. It is never asserted in master mode. It indicates that a frame synchronization (FS) has been detected earlier than expected since the frame length, the frame polarity, and the frame offset are defined and known.

Anticipated frame detection sets the AFSDET flag in the SAI\_xSR register.

This detection has no effect on the current audio frame, which is not sensitive to the anticipated FS. This means that “parasitic” events on signal FS are flagged without any perturbation of the current audio frame.

An interrupt is generated if the AFSDETIE bit is set in the SAI\_xIM register. To clear the AFSDET flag, the CAFSDET bit must be set in the SAI\_xCLRFR register.

To resynchronize with the master after an anticipated frame detection error, four steps are required:

1. Disable the SAI block by resetting the SAIEN bit in the SAI\_xCR1 register. To make sure that the SAI is disabled, read back the SAIEN bit and check it is set to 0.
2. Flush the FIFO via the FFLUS bit in the SAI\_xCR2 register.
3. Enable the SAI peripheral again (SAIEN bit set to 1).
4. The SAI block waits for the assertion on FS to restart the synchronization with master.

*Note: The AFSDET flag is not asserted in AC'97 mode since the SAI audio block acts as a link controller and generates the FS signal even when declared as slave. It has no meaning in SPDIF mode since the FS signal is not used.*

### Late frame synchronization detection

The LFSDET flag in the SAI\_xSR register can be set only when the SAI audio block operates as a slave. The frame length, the frame polarity, and the frame-offset configuration are known in register SAI\_xFRCR.

If the external master does not send the FS signal at the expected time, thus generating the signal too late, the LFSDET flag is set and an interrupt is generated if the LFSDETIE bit is set in the SAI\_xIM register.

The LFSDET flag is cleared when the CLFSDET bit is set in the SAI\_xCLRFR register.

The late frame synchronization detection flag is set when the corresponding error is detected. The SAI needs to be resynchronized with the master (see sequence described in [Anticipated frame synchronization detection \(AFSDET\)](#)).

In a noisy environment, glitches on the SCK clock may be wrongly detected by the audio block state machine and shift the SAI data at a wrong frame position. This event can be detected by the SAI and reported as a late frame synchronization detection error.

There is no corruption if the external master is not managing the audio data frame transfer in continuous mode, which must not be the case in most applications. In this case, the LFSDET flag is set.

*Note: The LFSDET flag is not asserted in AC'97 mode since the SAI audio block acts as a link controller and generates the FS signal even when declared as slave. It has no meaning in SPDIF mode since the signal FS is not used by the protocol.*

### Codec not ready (CNRDY AC'97)

The CNRDY flag in the SAI\_xSR register is relevant only if the SAI audio block is configured to operate in AC'97 mode (PRTCFCFG[1:0] = 10 in the SAI\_xCR1 register). If the CNRDYIE bit is set in the SAI\_xIM register, an interrupt is generated when the CNRDY flag is set.

CNRDY is asserted when the codec is not ready to communicate during the reception of the TAG 0 (slot 0) of the AC'97 audio frame. In this case, no data are automatically stored into the FIFO since the codec is not ready, until the TAG 0 indicates that the codec is ready. All the active slots defined in the SAI\_xSLOTR register are captured when the codec is ready.

To clear the CNRDY flag, the CCNRDY bit must be set in the SAI\_xCLRFR register.

### Wrong clock configuration in master mode (with NODIV = 0)

When the audio block operates as a master (MODE[1] = 0) and the NODIV bit is equal to 0, the WCKCFG flag is set as soon as the SAI is enabled if the following conditions are met:

- (FRL+1) is not a power of 2, and
- (FRL+1) is not between 8 and 256.

The MODE, NODIV, and SAIEN bits belong to the SAI\_xCR1 register and FRL to the SAI\_xFRCR register.

If the WCKCFGIE bit is set, an interrupt is generated when the WCKCFG flag is set in the SAI\_xSR register. To clear this flag, set the CWCKCFG bit in the SAI\_xCLRFR register.

When the WCKCFG bit is set, the audio block is automatically disabled, thus performing a hardware clear of the SAIEN bit.

## 43.3.14 Disabling the SAI

The SAI audio block can be disabled at any moment by clearing the SAIEN bit in the SAI\_xCR1 register. All the already started frames are automatically completed before the SAI stops working. The SAIEN bit remains high until the SAI is completely switched off at the end of the current audio frame transfer.

If an audio block in the SAI operates synchronously with the other one, the one that is the master must be disabled first.

## 43.3.15 SAI DMA interface

To free the CPU and to optimize bus bandwidth, each SAI audio block has an independent DMA interface to read/write from/to the SAI\_xDR register (to access the internal FIFO). There is one DMA channel per audio subblock supporting the basic DMA request/acknowledge protocol.

To configure the audio subblock for DMA transfer, set the DMAEN bit in the SAI\_xCR1 register. The DMA request is managed directly by the FIFO controller depending on the FIFO threshold level (for more details refer to [Section 43.3.9: Internal FIFOs](#)). The DMA transfer direction is linked to the SAI audio subblock configuration:

- If the audio block operates as a transmitter, the audio block FIFO controller outputs a DMA request to load the FIFO with data written in the SAI\_xDR register.
- If the audio block operates as a receiver, the DMA request is related to read operations from the SAI\_xDR register.

Follow the sequence below to configure the SAI interface in DMA mode:

1. Configure the SAI and FIFO threshold levels to specify when the DMA request is launched.
2. Configure the SAI DMA channel.
3. Enable the DMA.
4. Enable the SAI interface.

## 43.4 SAI interrupts

The SAI supports 7 interrupt sources, as shown in [Table 274](#).

**Table 274. SAI interrupt sources**

| Interrupt acronym | Interrupt source | Interrupt group | Audio block mode                                 | Interrupt enable              | Interrupt clear                                                                                                                                                                                        |
|-------------------|------------------|-----------------|--------------------------------------------------|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|                   | OVRUDR           | ERROR           | Master or slave<br>Receiver or transmitter       | OVRUDRIE in SAI_xIM register  | COVRUDR = 1 in SAI_xCLRFR register                                                                                                                                                                     |
|                   | AFSDDET          | ERROR           | Slave<br>(not used in AC'97 mode and SPDIF mode) | AFSDDETIE in SAI_xIM register | CAFSDET = 1 in SAI_xCLRFR register                                                                                                                                                                     |
|                   | LFSDDET          | ERROR           | Slave<br>(not used in AC'97 mode and SPDIF mode) | LFSDDETIE in SAI_xIM register | CLFSDET = 1 in SAI_xCLRFR register                                                                                                                                                                     |
|                   | CNRDY            | ERROR           | Slave<br>(only in AC'97 mode)                    | CNRDYIE in SAI_xIM register   | CCNRDY = 1 in SAI_xCLRFR register                                                                                                                                                                      |
|                   | MUTEDET          | MUTE            | Master or slave<br>Receiver mode only            | MUTEDETIE in SAI_xIM register | CMUTEDET = 1 in SAI_xCLRFR register                                                                                                                                                                    |
|                   | WCKCFG           | ERROR           | Master with NODIV = 0 in SAI_xCR1 register       | WCKCFGIE in SAI_xIM register  | CWCKCFG = 1 in SAI_xCLRFR register                                                                                                                                                                     |

Follow the sequence below to enable an interrupt:

1. Disable SAI interrupt.
2. Configure SAI.
3. Configure SAI interrupt source.
4. Enable SAI.

## 43.5 SAI registers

The peripheral registers have to be accessed by words (32 bits).

### 43.5.1 SAI global configuration register (SAI\_GCR)

Address offset: 0x00

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |      |              |      |      |      |             |      |
|------|------|------|------|------|------|------|------|------|------|--------------|------|------|------|-------------|------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21           | 20   | 19   | 18   | 17          | 16   |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.         | Res. | Res. | Res. | Res.        | Res. |
|      |      |      |      |      |      |      |      |      |      |              |      |      |      |             |      |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5            | 4    | 3    | 2    | 1           | 0    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | SYNCOUT[1:0] |      | Res. | Res. | SYNCIN[1:0] |      |
|      |      |      |      |      |      |      |      |      |      | rw           | rw   |      |      | rw          | rw   |

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:4 **SYNCOUT[1:0]**: Synchronization outputs

These bits are set and cleared by software.

00: No synchronization output signals. SYNCOUT[1:0] must be configured as "No synchronization output signals" when audio block is configured as SPDIF

01: Block A used for further synchronization for others SAI

10: Block B used for further synchronization for others SAI

11: Reserved. These bits must be set when both audio block (A and B) are disabled.

Bits 3:2 Reserved, must be kept at reset value.

Bits 1:0 **SYNCIN[1:0]**: Synchronization inputs

These bits are set and cleared by software.

Refer to [Table 269: External synchronization selection](#) for information on how to program this field.

These bits must be set when both audio blocks (A and B) are disabled.

They are meaningful if one of the two audio blocks is defined to operate in synchronous mode with an external SAI (SYNCEN[1:0] = 10 in SAI\_ACR1 or in SAI\_BCR1 registers).

### 43.5.2 SAI configuration register 1 (SAI\_ACR1)

Address offset: 0x0004

Reset value: 0x0000 0040

|      |      |          |      |             |      |       |          |             |    |    |      |              |      |           |       |
|------|------|----------|------|-------------|------|-------|----------|-------------|----|----|------|--------------|------|-----------|-------|

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:20 MCKDIV[3:0]: Master clock divider

These bits are set and cleared by software. These bits are meaningless when the audio block operates in slave mode. They have to be configured when the audio block is disabled.

0000: Divides by 1 the master clock input.

Others: the master clock frequency is calculated accordingly to the following formula:

$$F_{SCK\_x} = \frac{F_{sai\_x\_ker\_ck}}{MCKDIV \times 2}$$

Bit 19 **NODIV**: No divider

This bit is set and cleared by software.

0: Master clock generator is enabled

1: No divider used in the clock generator (in this case Master Clock Divider bit has no effect)

Bit 18 Reserved, must be kept at reset value.

Bit 17 **DMAEN**: DMA enable

This bit is set and cleared by software.

0: DMA disabled

1: DMA enabled

*Note: Since the audio block defaults to operate as a transmitter after reset, the MODE[1:0] bits must be configured before setting DMAEN to avoid a DMA request in receiver mode.*

Bit 16 **SAIEN**: Audio block enable

This bit is set by software.

To switch off the audio block, the application software must program this bit to 0 and poll the bit till it reads back 0, meaning that the block is completely disabled. Before setting this bit to 1, check that it is set to 0, otherwise the enable command is not taken into account.

This bit enables to control the state of the SAI audio block. If it is disabled when an audio frame transfer is ongoing, the ongoing transfer completes and the cell is fully disabled at the end of this audio frame transfer.

0: SAI audio block disabled

1: SAI audio block enabled.

*Note: When the SAI block (A or B) is configured in master mode, the clock must be present on the SAI block input before setting SAIEN bit.*

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **OUTDRIV**: Output drive

This bit is set and cleared by software.

0: Audio block output driven when SAIEN is set

1: Audio block output driven immediately after the setting of this bit.

*Note: This bit has to be set before enabling the audio block and after the audio block configuration.*

Bit 12 **MONO**: Mono mode

This bit is set and cleared by software. It is meaningful only when the number of slots is equal to 2. When the mono mode is selected, slot 0 data are duplicated on slot 1 when the audio block operates as a transmitter. In reception mode, the slot1 is discarded and only the data received from slot 0 are stored. Refer to [Section : Mono/stereo mode](#) for more details.

0: Stereo mode

1: Mono mode.

Bits 11:10 **SYNCEN[1:0]**: Synchronization enable

These bits are set and cleared by software. They must be configured when the audio subblock is disabled.

00: audio subblock in asynchronous mode.

01: audio subblock is synchronous with the other internal audio subblock. In this case, the audio subblock must be configured in slave mode

10: audio subblock is synchronous with an external SAI embedded peripheral. In this case the audio subblock must be configured in Slave mode.

11: Reserved

*Note: The audio subblock must be configured as asynchronous when SPDIF mode is enabled.*

Bit 9 **CKSTR**: Clock strobing edge

This bit is set and cleared by software. It must be configured when the audio block is disabled. This bit has no meaning in SPDIF audio protocol.

0: Signals generated by the SAI change on SCK rising edge, while signals received by the SAI are sampled on the SCK falling edge.

1: Signals generated by the SAI change on SCK falling edge, while signals received by the SAI are sampled on the SCK rising edge.

Bit 8 **LSBFIRST**: Least significant bit first

This bit is set and cleared by software. It must be configured when the audio block is disabled. This bit has no meaning in AC'97 audio protocol since AC'97 data are always transferred with the MSB first. This bit has no meaning in SPDIF audio protocol since in SPDIF data are always transferred with LSB first.

0: Data are transferred with MSB first

1: Data are transferred with LSB first

Bits 7:5 **DS[2:0]**: Data size

These bits are set and cleared by software. These bits are ignored when the SPDIF protocols are selected (bit PRTCFG[1:0]), because the frame and the data size are fixed in such case. When the companding mode is selected through COMP[1:0] bits, DS[1:0] are ignored since the data size is fixed to 8 bits by the algorithm.

These bits must be configured when the audio block is disabled.

000: Reserved

001: Reserved

010: 8 bits

011: 10 bits

100: 16 bits

101: 20 bits

110: 24 bits

111: 32 bits

Bit 4 Reserved, must be kept at reset value.

Bits 3:2 **PRTCFG[1:0]**: Protocol configuration

These bits are set and cleared by software. These bits have to be configured when the audio block is disabled.

00: Free protocol. Free protocol enables to use the powerful configuration of the audio block to address a specific audio protocol (such as I2S, LSB/MSB justified, TDM, PCM/DSP...) by setting most of the configuration register bits as well as frame configuration register.

01: SPDIF protocol

10: AC'97 protocol

11: Reserved

Bits 1:0 **MODE[1:0]**: SAIx audio block mode

These bits are set and cleared by software. They must be configured when SAIx audio block is disabled.

00: Master transmitter

01: Master receiver

10: Slave transmitter

11: Slave receiver

*Note: When the audio block is configured in SPDIF mode, the master transmitter mode is forced (MODE[1:0] = 00).*

### 43.5.3 SAI configuration register 2 (SAI\_ACR2)

Address offset: 0x0008

Reset value: 0x0000 0000

|           |    |      |    |              |    |      |    |      |    |      |    |      |    |          |      |      |         |          |    |      |    |      |    |      |    |      |    |      |  |      |  |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:14 **COMP[1:0]**: Companding mode.

These bits are set and cleared by software. The  $\mu$ -Law and the A-Law log are a part of the CCITT G.711 recommendation, the type of complement that is used depends on *CPL bit*.

The data expansion or data compression are determined by the state of bit *MODE[0]*.

The data compression is applied if the audio block is configured as a transmitter.

The data expansion is automatically applied when the audio block is configured as a receiver.

Refer to [Section : Companding mode](#) for more details.

00: No companding algorithm

01: Reserved.

10:  $\mu$ -Law algorithm

11: A-Law algorithm

*Note: Companding mode is applicable only when Free protocol mode is selected.*

Bit 13 **CPL**: Complement bit.

This bit is set and cleared by software.

It defines the type of complement to be used for companding mode

0: 1's complement representation.

1: 2's complement representation.

*Note: This bit has effect only when the companding mode is  $\mu$ -Law algorithm or A-Law algorithm.*

Bits 12:7 **MUTECNT[5:0]**: Mute counter.

These bits are set and cleared by software. They are used only in reception mode.

The value set in these bits is compared to the number of consecutive mute frames detected in reception. When the number of mute frames is equal to this value, the flag *MUTEDET* is set and an interrupt is generated if bit *MUTEDETIE* is set.

Refer to [Section : Mute mode](#) for more details.

**Bit 6 MUTEVAL:** Mute value.

This bit is set and cleared by software. It must be written before enabling the audio block: SAIEN. This bit is meaningful only when the audio block operates as a transmitter, the number of slots is lower or equal to 2 and the MUTE bit is set.

If more slots are declared, the bit value sent during the transmission in mute mode is equal to 0, whatever the value of MUTEVAL.

If the number of slot is lower or equal to 2 and MUTEVAL = 1, the MUTE value transmitted for each slot is the one sent during the previous frame.

Refer to [Section : Mute mode](#) for more details.

0: Bit value 0 is sent during the mute mode.

1: Last values are sent during the mute mode.

*Note: This bit is meaningless and must not be used for SPDIF audio blocks.*

**Bit 5 MUTE:** Mute.

This bit is set and cleared by software. It is meaningful only when the audio block operates as a transmitter. The MUTE value is linked to value of MUTEVAL if the number of slots is lower or equal to 2, or equal to 0 if it is greater than 2.

Refer to [Section : Mute mode](#) for more details.

0: No mute mode.

1: Mute mode enabled.

*Note: This bit is meaningless and must not be used for SPDIF audio blocks.*

**Bit 4 TRIS:** Tristate management on data line.

This bit is set and cleared by software. It is meaningful only if the audio block is configured as a transmitter. This bit is not used when the audio block is configured in SPDIF mode. It must be configured when SAI is disabled.

Refer to [Section : Output data line management on an inactive slot](#) for more details.

0: SD output line is still driven by the SAI when a slot is inactive.

1: SD output line is released (HI-Z) at the end of the last data bit of the last active slot if the next one is inactive.

**Bit 3 FFLUSH:** FIFO flush.

This bit is set by software. It is always read as 0. This bit must be configured when the SAI is disabled.

0: No FIFO flush.

1: FIFO flush. Programming this bit to 1 triggers the FIFO Flush. All the internal FIFO pointers (read and write) are cleared. In this case data still present in the FIFO are lost (no more transmission or received data lost). Before flushing, SAI DMA stream/interrupt must be disabled

**Bits 2:0 FTH[2:0]:** FIFO threshold.

This bit is set and cleared by software.

000: FIFO empty

001: ¼ FIFO

010: ½ FIFO

011: ¾ FIFO

100: FIFO full

101: Reserved

110: Reserved

111: Reserved

### 43.5.4 SAI frame configuration register (SAI\_AFRCR)

Address offset: 0x000C

Reset value: 0x0000 0007

**Note:** This register has no meaning in AC'97 and SPDIF audio protocol.

|      |            |      |      |      |      |      |      |          |      |      |      |      |       |       |       |

|      |            |      |      |      |      |      |      |          |      |      |      |      | rw    | rw    | r     |
| 15   | 14         | 13   | 12   | 11   | 10   | 9    | 8    | 7        | 6    | 5    | 4    | 3    | 2     | 1     | 0     |
| Res. | FSALL[6:0] |      |      |      |      |      |      | FRL[7:0] |      |      |      |      |       |       |       |
|      | rw         | rw   | rw   | rw   | rw   | rw   | rw   | rw       | rw   | rw   | rw   | rw   | rw    | rw    | rw    |

Bits 31:19 Reserved, must be kept at reset value.

Bit 18 **FSOFF**: Frame synchronization offset.

This bit is set and cleared by software. It is meaningless and is not used in AC'97 or SPDIF audio block configuration. This bit must be configured when the audio block is disabled.

0: FS is asserted on the first bit of the slot 0.

1: FS is asserted one bit before the first bit of the slot 0.

Bit 17 **FSPOL**: Frame synchronization polarity.

This bit is set and cleared by software. It is used to configure the level of the start of frame on the FS signal. It is meaningless and is not used in AC'97 or SPDIF audio block configuration.

This bit must be configured when the audio block is disabled.

0: FS is active low (falling edge)

1: FS is active high (rising edge)

Bit 16 **FSDEF**: Frame synchronization definition.

This bit is set and cleared by software.

0: FS signal is a start frame signal

1: FS signal is a start of frame signal + channel side identification

When the bit is set, the number of slots defined in the SAI\_xSLOTR register has to be even. It means that half of this number of slots are dedicated to the left channel and the other slots for the right channel (e.g: this bit has to be set for I2S or MSB/LSB-justified protocols...).

This bit is meaningless and is not used in AC'97 or SPDIF audio block configuration. It must be configured when the audio block is disabled.

Bit 15 Reserved, must be kept at reset value.

Bits 14:8 **FSALL[6:0]**: Frame synchronization active level length.

These bits are set and cleared by software. They specify the length in number of bit clock (SCK) + 1 (FSALL[6:0] + 1) of the active level of the FS signal in the audio frame

These bits are meaningless and are not used in AC'97 or SPDIF audio block configuration.

They must be configured when the audio block is disabled.

Bits 7:0 **FRL[7:0]**: Frame length.

These bits are set and cleared by software. They define the audio frame length expressed in number of SCK clock cycles: the number of bits in the frame is equal to  $FRL[7:0] + 1$ .

The minimum number of bits to transfer in an audio frame must be equal to 8, otherwise the audio block behaves in an unexpected way. This is the case when the data size is 8 bits and only one slot 0 is defined in NBSLOT[4:0] of SAI\_xSLOTR register (NBSLOT[3:0] = 0000).

In master mode, if the master clock (available on MCLK\_x pin) is used, the frame length must be aligned with a number equal to a power of 2, ranging from 8 to 256. When the master clock is not used (NODIV = 1), it is recommended to program the frame length to an value ranging from 8 to 256.

These bits are meaningless and are not used in AC'97 or SPDIF audio block configuration. They must be configured when the audio block is disabled.

### 43.5.5 SAI slot register (SAI\_ASLOTR)

Address offset: 0x0010

Reset value: 0x0000 0000

*Note: This register has no meaning in AC'97 and SPDIF audio protocol.*

|              |      |      |      |             |    |    |    |             |    |      |            |    |    |    |    |

| Res.         | Res. | Res. | Res. | NBSLOT[3:0] |    |    |    | SLOTSZ[1:0] |    | Res. | FBOFF[4:0] |    |    |    |    |
|              |      |      |      | rw          | rw | rw | rw | rw          | rw |      | rw         | rw | rw | rw | rw |

Bits 31:16 **SLOTEN[15:0]**: Slot enable.

These bits are set and cleared by software.

Each SLOTEN bit corresponds to a slot position from 0 to 15 (maximum 16 slots).

0: Inactive slot.

1: Active slot.

The slot must be enabled when the audio block is disabled.

They are ignored in AC'97 or SPDIF mode.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:8 **NBSLOT[3:0]**: Number of slots in an audio frame.

These bits are set and cleared by software.

The value set in this bitfield represents the number of slots + 1 in the audio frame (including the number of inactive slots). The maximum number of slots is 16.

The number of slots must be even if FSDEF bit in the SAI\_xFRCR register is set.

The number of slots must be configured when the audio block is disabled.

They are ignored in AC'97 or SPDIF mode.

Bits 7:6 **SLOTSZ[1:0]**: Slot size

This bits is set and cleared by software.

The slot size must be higher or equal to the data size. If this condition is not respected, the behavior of the SAI is undetermined.

Refer to [Output data line management on an inactive slot](#) for information on how to drive SD line.

These bits must be set when the audio block is disabled.

They are ignored in AC'97 or SPDIF mode.

00: The slot size is equivalent to the data size (specified in DS[3:0] in the SAI\_xCR1 register).

01: 16-bit

10: 32-bit

11: Reserved

Bit 5 Reserved, must be kept at reset value.

Bits 4:0 **FBOFF[4:0]**: First bit offset

These bits are set and cleared by software.

The value set in this bitfield defines the position of the first data transfer bit in the slot. It represents an offset value. In transmission mode, the bits outside the data field are forced to 0. In reception mode, the extra received bits are discarded.

These bits must be set when the audio block is disabled.

They are ignored in AC'97 or SPDIF mode.

### 43.5.6 SAI interrupt mask register (SAI\_AIM)

Address offset: 0x0014

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |              |              |             |            |              |               |              |

| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | LFSDET<br>IE | AFSDETI<br>E | CNRDY<br>IE | FREQ<br>IE | WCKCFG<br>IE | MUTEDET<br>IE | OVRUDR<br>IE |
|      |      |      |      |      |      |      |      |      | rw           | rw           | rw          | rw         | rw           | rw            | rw           |

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **LFSDETIE**: Late frame synchronization detection interrupt enable.

This bit is set and cleared by software.

0: Interrupt is disabled

1: Interrupt is enabled

When this bit is set, an interrupt is generated if the LFSDET bit is set in the SAI\_xSR register.

This bit is meaningless in AC'97, SPDIF mode or when the audio block operates as a master.

Bit 5 **AFSDETIE**: Anticipated frame synchronization detection interrupt enable.

This bit is set and cleared by software.

0: Interrupt is disabled

1: Interrupt is enabled

When this bit is set, an interrupt is generated if the AFSDET bit in the SAI\_xSR register is set.

This bit is meaningless in AC'97, SPDIF mode or when the audio block operates as a master.

Bit 4 **CNRDYIE**: Codec not ready interrupt enable (AC'97).

This bit is set and cleared by software.

0: Interrupt is disabled

1: Interrupt is enabled

When the interrupt is enabled, the audio block detects in the slot 0 (tag0) of the AC'97 frame if the Codec connected to this line is ready or not. If it is not ready, the CNRDY flag in the SAI\_xSR register is set and an interrupt is generated.

This bit has a meaning only if the AC'97 mode is selected through PRTCFG[1:0] bits and the audio block is operates as a receiver.

Bit 3 **FREQIE**: FIFO request interrupt enable.

This bit is set and cleared by software.

0: Interrupt is disabled

1: Interrupt is enabled

When this bit is set, an interrupt is generated if the FREQ bit in the SAI\_xSR register is set.

Since the audio block defaults to operate as a transmitter after reset, the MODE bit must be configured before setting FREQIE to avoid a parasitic interrupt in receiver mode,

Bit 2 **WCKCFGIE**: Wrong clock configuration interrupt enable.

This bit is set and cleared by software.

0: Interrupt is disabled

1: Interrupt is enabled

This bit is taken into account only if the audio block is configured as a master (MODE[1] = 0) and NODIV = 0.

It generates an interrupt if the WCKCFG flag in the SAI\_xSR register is set.

*Note: This bit is used only in Free protocol mode and is meaningless in other modes.*

Bit 1 **MUTEDETIE**: Mute detection interrupt enable.

This bit is set and cleared by software.

0: Interrupt is disabled

1: Interrupt is enabled

When this bit is set, an interrupt is generated if the MUTEDET bit in the SAI\_xSR register is set.

This bit has a meaning only if the audio block is configured in receiver mode.

Bit 0 **OVRUDRIE**: Overrun/underrun interrupt enable.

This bit is set and cleared by software.

0: Interrupt is disabled

1: Interrupt is enabled

When this bit is set, an interrupt is generated if the OVRUDR bit in the SAI\_xSR register is set.

### 43.5.7 SAI status register (SAI\_ASR)

Address offset: 0x0018

Reset value: 0x0000 0008

| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | LFSDET | AFSDDET | CNRDY | FREQ | WCKCFG    | MUTEDET | OVRUDR |
|      |      |      |      |      |      |      |      |      | r      | r       | r     | r    | r         | r       | r      |

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:16 **FLVL[2:0]**: FIFO level threshold.

This bit is read only. The FIFO level threshold flag is managed only by hardware and its setting depends on SAI block configuration (transmitter or receiver mode).

000: FIFO empty (transmitter and receiver modes)

001:  $\text{FIFO} \leq \frac{1}{4}$  but not empty (transmitter mode),  $\text{FIFO} < \frac{1}{4}$  but not empty (receiver mode)

010:  $\frac{1}{4} < \text{FIFO} \leq \frac{1}{2}$  (transmitter mode),  $\frac{1}{4} \leq \text{FIFO} < \frac{1}{2}$  (receiver mode)

011:  $\frac{1}{2} < \text{FIFO} \leq \frac{3}{4}$  (transmitter mode),  $\frac{1}{2} \leq \text{FIFO} < \frac{3}{4}$  (receiver mode)

100:  $\frac{3}{4} < \text{FIFO}$  but not full (transmitter mode),  $\frac{3}{4} \leq \text{FIFO}$  but not full (receiver mode)

101: FIFO full (transmitter and receiver modes)

Others: Reserved

Bits 15:7 Reserved, must be kept at reset value.

Bit 6 **LFSDET**: Late frame synchronization detection.

This bit is read only.

0: No error.

1: Frame synchronization signal is not present at the right time.

This flag can be set only if the audio block is configured in slave mode.

It is not used in AC'97 or SPDIF mode.

It can generate an interrupt if LFSDETIE bit is set in the SAI\_xIM register.

This flag is cleared when the software sets bit CLFSDET in SAI\_xCLRFR register

Bit 5 **AFSDET**: Anticipated frame synchronization detection.

This bit is read only.

0: No error.

1: Frame synchronization signal is detected earlier than expected.

This flag can be set only if the audio block is configured in slave mode.

It is not used in AC'97 or SPDIF mode.

It can generate an interrupt if AFSDETIE bit is set in SAI\_xIM register.

This flag is cleared when the software sets CAFSDET bit in SAI\_xCLRFR register.

Bit 4 **CNRDY**: Codec not ready.

This bit is read only.

0: External AC'97 Codec is ready

1: External AC'97 Codec is not ready

This bit is used only when the AC'97 audio protocol is selected in the SAI\_xCR1 register and configured in receiver mode.

It can generate an interrupt if CNRDYIE bit is set in SAI\_xIM register.

This flag is cleared when the software sets CCNRDY bit in SAI\_xCLRFR register.

Bit 3 **FREQ**: FIFO request.

This bit is read only.

0: No FIFO request.

1: FIFO request to read or to write the SAI\_xDR.

The request depends on the audio block configuration:

- If the block is configured in transmission mode, the FIFO request is related to a write request operation in the SAI\_xDR.
- If the block configured in reception, the FIFO request related to a read request operation from the SAI\_xDR.

This flag can generate an interrupt if FREQIE bit is set in SAI\_xIM register.

Bit 2 **WCKCFG**: Wrong clock configuration flag.

This bit is read only.

0: Clock configuration is correct

1: Clock configuration does not respect the rule concerning the frame length specification defined in [Section 43.3.6: Frame synchronization](#) (configuration of FRL[7:0] bit in the SAI\_xFRCR register)

This bit is used only when the audio block operates in master mode (MODE[1] = 0) and NODIV = 0.

It can generate an interrupt if WCKCFGIE bit is set in SAI\_xIM register.

This flag is cleared when the software sets CWCKCFG bit in SAI\_xCLRFR register.

Bit 1 **MUTEDET**: Mute detection.

This bit is read only.

0: No MUTE detection on the SD input line

1: MUTE value detected on the SD input line (0 value) for a specified number of consecutive audio frame

This flag is set if consecutive 0 values are received in each slot of a given audio frame and for a consecutive number of audio frames (set in the MUTEcnt bit in the SAI\_xCR2 register).

It can generate an interrupt if MUTEDETIE bit is set in SAI\_xIM register.

This flag is cleared when the software sets bit CMUTEDET in the SAI\_xCLRFR register.

Bit 0 **OVRUDR**: Overrun / underrun.

This bit is read only.

0: No overrun/underrun error.

1: Overrun/underrun error detection.

The overrun and underrun conditions can occur only when the audio block is configured as a receiver and a transmitter, respectively.

It can generate an interrupt if OVRUDRIE bit is set in SAI\_xIM register.

This flag is cleared when the software sets COVRUDR bit in SAI\_xCLRFR register.

### 43.5.8 SAI clear flag register (SAI\_ACLRFR)

Address offset: 0x001C

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |         |         |        |      |         |          |         |

| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | CLFSDET | CAFSDET | CCNRDY | Res. | CWCKCFG | CMUTEDET | COVRUDR |
|      |      |      |      |      |      |      |      |      | w       | w       | w      |      | w       | w        | w       |

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **CLFSDET**: Clear late frame synchronization detection flag.

This bit is write only.

Programming this bit to 1 clears the LFSDET flag in the SAI\_xSR register.

This bit is not used in AC'97 or SPDIF mode

Reading this bit always returns the value 0.

Bit 5 **CAFSDET**: Clear anticipated frame synchronization detection flag.

This bit is write only.

Programming this bit to 1 clears the AFSDET flag in the SAI\_xSR register.

It is not used in AC'97 or SPDIF mode.

Reading this bit always returns the value 0.

Bit 4 **CCNRDY**: Clear Codec not ready flag.

This bit is write only.

Programming this bit to 1 clears the CNRDY flag in the SAI\_xSR register.

This bit is used only when the AC'97 audio protocol is selected in the SAI\_xCR1 register.

Reading this bit always returns the value 0.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **WCKCFG**: Clear wrong clock configuration flag.

This bit is write only.

Programming this bit to 1 clears the WCKCFG flag in the SAI\_xSR register.

This bit is used only when the audio block is set as master (MODE[1] = 0) and NODIV = 0 in the SAI\_xCR1 register.

Reading this bit always returns the value 0.

Bit 1 **CMUTEDET**: Mute detection flag.

This bit is write only.

Programming this bit to 1 clears the MUTEDET flag in the SAI\_xSR register.

Reading this bit always returns the value 0.

Bit 0 **COVRUDR**: Clear overrun / underrun.

This bit is write only.

Programming this bit to 1 clears the OVRUDR flag in the SAI\_xSR register.

Reading this bit always returns the value 0.

### 43.5.9 SAI data register (SAI\_ADR)

Address offset: 0x0020

Reset value: 0x0000 0000

|             |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31          | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| DATA[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw          | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

| Res. | Res. | OUTD<br>RIV | MONO | SYNCEN[1:0] |      | CKSTR | LSBFIRST | DS[2:0]     |    |    | Res. | PRTCFCG[1:0] |      | MODE[1:0] |       |
|      |      | rw          | rw   | rw          | rw   | rw    | rw       | rw          | rw | rw |      | rw           | rw   | rw        | rw    |

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:20 MCKDIV[3:0]: Master clock divider

These bits are set and cleared by software. These bits are meaningless when the audio block operates in slave mode. They have to be configured when the audio block is disabled.

0000: Divides by 1 the master clock input.

Others: the master clock frequency is calculated accordingly to the following formula:

$$F_{SCK\_x} = \frac{F_{sai\_x\_ker\_ck}}{MCKDIV \times 2}$$

Bit 19 **NODIV**: No divider

This bit is set and cleared by software.

0: Master clock generator is enabled

1: No divider used in the clock generator (in this case Master Clock Divider bit has no effect)

Bit 18 Reserved, must be kept at reset value.

Bit 17 **DMAEN**: DMA enable

This bit is set and cleared by software.

0: DMA disabled

1: DMA enabled

*Note: Since the audio block defaults to operate as a transmitter after reset, the MODE[1:0] bits must be configured before setting DMAEN to avoid a DMA request in receiver mode.*

Bit 16 **SAIEN**: Audio block enable

This bit is set by software.

To switch off the audio block, the application software must program this bit to 0 and poll the bit till it reads back 0, meaning that the block is completely disabled. Before setting this bit to 1, check that it is set to 0, otherwise the enable command is not taken into account.

This bit enables to control the state of the SAI audio block. If it is disabled when an audio frame transfer is ongoing, the ongoing transfer completes and the cell is fully disabled at the end of this audio frame transfer.

0: SAI audio block disabled

1: SAI audio block enabled.

*Note: When the SAI block (A or B) is configured in master mode, the clock must be present on the SAI block input before setting SAIEN bit.*

Bits 15:14 Reserved, must be kept at reset value.

**Bit 13 OUTDRIV:** Output drive

This bit is set and cleared by software.

0: Audio block output driven when SAIEN is set

1: Audio block output driven immediately after the setting of this bit.

*Note: This bit has to be set before enabling the audio block and after the audio block configuration.*

**Bit 12 MONO:** Mono mode

This bit is set and cleared by software. It is meaningful only when the number of slots is equal to 2. When the mono mode is selected, slot 0 data are duplicated on slot 1 when the audio block operates as a transmitter. In reception mode, the slot1 is discarded and only the data received from slot 0 are stored. Refer to [Section : Mono/stereo mode](#) for more details.

0: Stereo mode

1: Mono mode.

**Bits 11:10 SYNCEN[1:0]:** Synchronization enable

These bits are set and cleared by software. They must be configured when the audio subblock is disabled.

00: audio subblock in asynchronous mode.

01: audio subblock is synchronous with the other internal audio subblock. In this case, the audio subblock must be configured in slave mode

10: audio subblock is synchronous with an external SAI embedded peripheral. In this case the audio subblock must be configured in Slave mode.

11: Reserved

*Note: The audio subblock must be configured as asynchronous when SPDIF mode is enabled.*

**Bit 9 CKSTR:** Clock strobing edge

This bit is set and cleared by software. It must be configured when the audio block is disabled. This bit has no meaning in SPDIF audio protocol.

0: Signals generated by the SAI change on SCK rising edge, while signals received by the SAI are sampled on the SCK falling edge.

1: Signals generated by the SAI change on SCK falling edge, while signals received by the SAI are sampled on the SCK rising edge.

**Bit 8 LSBFIRST:** Least significant bit first

This bit is set and cleared by software. It must be configured when the audio block is disabled. This bit has no meaning in AC'97 audio protocol since AC'97 data are always transferred with the MSB first. This bit has no meaning in SPDIF audio protocol since in SPDIF data are always transferred with LSB first.

0: Data are transferred with MSB first

1: Data are transferred with LSB first

**Bits 7:5 DS[2:0]:** Data size

These bits are set and cleared by software. These bits are ignored when the SPDIF protocols are selected (bit PRTCFG[1:0]), because the frame and the data size are fixed in such case. When the companding mode is selected through COMP[1:0] bits, DS[1:0] are ignored since the data size is fixed to 8 bits by the algorithm.

These bits must be configured when the audio block is disabled.

000: Reserved

001: Reserved

010: 8 bits

011: 10 bits

100: 16 bits

101: 20 bits

110: 24 bits

111: 32 bits

Bit 4 Reserved, must be kept at reset value.

Bits 3:2 **PRTCFG[1:0]**: Protocol configuration

These bits are set and cleared by software. These bits have to be configured when the audio block is disabled.

00: Free protocol. Free protocol enables to use the powerful configuration of the audio block to address a specific audio protocol (such as I2S, LSB/MSB justified, TDM, PCM/DSP...) by setting most of the configuration register bits as well as frame configuration register.

01: SPDIF protocol

10: AC'97 protocol

11: Reserved

Bits 1:0 **MODE[1:0]**: SAIx audio block mode

These bits are set and cleared by software. They must be configured when SAIx audio block is disabled.

00: Master transmitter

01: Master receiver

10: Slave transmitter

11: Slave receiver

*Note: When the audio block is configured in SPDIF mode, the master transmitter mode is forced (MODE[1:0] = 00). In Master transmitter mode, the audio block starts generating the FS and the clocks immediately.*

### 43.5.11 SAI configuration register 2 (SAI\_BCR2)

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:14 **COMP[1:0]**: Companding mode.

These bits are set and cleared by software. The  $\mu$ -Law and the A-Law log are a part of the CCITT G.711 recommendation, the type of complement that is used depends on *CPL bit*.

The data expansion or data compression are determined by the state of bit MODE[0].

The data compression is applied if the audio block is configured as a transmitter.

The data expansion is automatically applied when the audio block is configured as a receiver.

Refer to [Section : Companding mode](#) for more details.

00: No companding algorithm

01: Reserved.

10:  $\mu$ -Law algorithm

11: A-Law algorithm

*Note: Companding mode is applicable only when Free protocol mode is selected.*

Bit 13 **CPL**: Complement bit.

This bit is set and cleared by software.

It defines the type of complement to be used for companding mode

0: 1's complement representation.

1: 2's complement representation.

*Note: This bit has effect only when the companding mode is  $\mu$ -Law algorithm or A-Law algorithm.*

Bits 12:7 **MUTECNT[5:0]**: Mute counter.

These bits are set and cleared by software. They are used only in reception mode.

The value set in these bits is compared to the number of consecutive mute frames detected in reception. When the number of mute frames is equal to this value, the flag MUTEDET is set and an interrupt is generated if bit MUTEDETIE is set.

Refer to [Section : Mute mode](#) for more details.

Bit 6 **MUTEVAL**: Mute value.

This bit is set and cleared by software. It must be written before enabling the audio block: SAIEN.

This bit is meaningful only when the audio block operates as a transmitter, the number of slots is lower or equal to 2 and the MUTE bit is set.

If more slots are declared, the bit value sent during the transmission in mute mode is equal to 0, whatever the value of MUTEVAL.

if the number of slot is lower or equal to 2 and MUTEVAL = 1, the MUTE value transmitted for each slot is the one sent during the previous frame.

Refer to [Section : Mute mode](#) for more details.

0: Bit value 0 is sent during the mute mode.

1: Last values are sent during the mute mode.

*Note: This bit is meaningless and must not be used for SPDIF audio blocks.*

Bit 5 **MUTE**: Mute.

This bit is set and cleared by software. It is meaningful only when the audio block operates as a transmitter. The MUTE value is linked to value of MUTEVAL if the number of slots is lower or equal to 2, or equal to 0 if it is greater than 2.

Refer to [Section : Mute mode](#) for more details.

0: No mute mode.

1: Mute mode enabled.

*Note: This bit is meaningless and must not be used for SPDIF audio blocks.*

Bit 4 **TRIS**: Tristate management on data line.

This bit is set and cleared by software. It is meaningful only if the audio block is configured as a transmitter. This bit is not used when the audio block is configured in SPDIF mode. It must be configured when SAI is disabled.

Refer to [Section : Output data line management on an inactive slot](#) for more details.

0: SD output line is still driven by the SAI when a slot is inactive.

1: SD output line is released (HI-Z) at the end of the last data bit of the last active slot if the next one is inactive.

Bit 3 **FFLUSH**: FIFO flush.

This bit is set by software. It is always read as 0. This bit must be configured when the SAI is disabled.

0: No FIFO flush.

1: FIFO flush. Programming this bit to 1 triggers the FIFO Flush. All the internal FIFO pointers (read and write) are cleared. In this case data still present in the FIFO are lost (no more transmission or received data lost). Before flushing, SAI DMA stream/interrupt must be disabled

Bits 2:0 **FTH[2:0]**: FIFO threshold.

This bit is set and cleared by software.

000: FIFO empty

001:  $\frac{1}{4}$  FIFO

010:  $\frac{1}{2}$  FIFO

011:  $\frac{3}{4}$  FIFO

100: FIFO full

101: Reserved

110: Reserved

111: Reserved

### 43.5.12 SAI frame configuration register (SAI\_BFRCR)

Address offset: 0x002C

Reset value: 0x0000 0007

*Note: This register has no meaning in AC'97 and SPDIF audio protocol*

|      |            |      |      |      |      |      |      |          |      |      |      |      |       |       |       |

| 31   | 30         | 29   | 28   | 27   | 26   | 25   | 24   | 23       | 22   | 21   | 20   | 19   | 18    | 17    | 16    |
| Res. | Res.       | Res. | Res. | Res. | Res. | Res. | Res. | Res.     | Res. | Res. | Res. | Res. | FSOFF | FSPOL | FSDEF |
|      |            |      |      |      |      |      |      |          |      |      |      |      | rw    | rw    | r     |
| 15   | 14         | 13   | 12   | 11   | 10   | 9    | 8    | 7        | 6    | 5    | 4    | 3    | 2     | 1     | 0     |
| Res. | FSALL[6:0] |      |      |      |      |      |      | FRL[7:0] |      |      |      |      |       |       |       |
|      | rw         | rw   | rw   | rw   | rw   | rw   | rw   | rw       | rw   | rw   | rw   | rw   | rw    | rw    | rw    |

Bits 31:19 Reserved, must be kept at reset value.

Bit 18 **FSOFF**: Frame synchronization offset.

This bit is set and cleared by software. It is meaningless and is not used in AC'97 or SPDIF audio block configuration. This bit must be configured when the audio block is disabled.

0: FS is asserted on the first bit of the slot 0.

1: FS is asserted one bit before the first bit of the slot 0.

Bit 17 **FSPOL**: Frame synchronization polarity.

This bit is set and cleared by software. It is used to configure the level of the start of frame on the FS signal. It is meaningless and is not used in AC'97 or SPDIF audio block configuration.

This bit must be configured when the audio block is disabled.

0: FS is active low (falling edge)

1: FS is active high (rising edge)

Bit 16 **FSDEF**: Frame synchronization definition.

This bit is set and cleared by software.

0: FS signal is a start frame signal

1: FS signal is a start of frame signal + channel side identification

When the bit is set, the number of slots defined in the SAI\_xSLOTR register has to be even. It means that half of this number of slots is dedicated to the left channel and the other slots for the right channel (e.g: this bit has to be set for I2S or MSB/LSB-justified protocols...).

This bit is meaningless and is not used in AC'97 or SPDIF audio block configuration. It must be configured when the audio block is disabled.

Bit 15 Reserved, must be kept at reset value.

Bits 14:8 **FSALL[6:0]**: Frame synchronization active level length.

These bits are set and cleared by software. They specify the length in number of bit clock (SCK) + 1 (FSALL[6:0] + 1) of the active level of the FS signal in the audio frame.  
These bits are meaningless and are not used in AC'97 or SPDIF audio block configuration.  
They must be configured when the audio block is disabled.

Bits 7:0 **FRL[7:0]**: Frame length.

These bits are set and cleared by software. They define the audio frame length expressed in number of SCK clock cycles: the number of bits in the frame is equal to FRL[7:0] + 1.

The minimum number of bits to transfer in an audio frame must be equal to 8, otherwise the audio block behaves in an unexpected way. This is the case when the data size is 8 bits and only one slot 0 is defined in NBSLOT[4:0] of SAI\_xSLOTR register (NBSLOT[3:0] = 0000).

In master mode, if the master clock (available on MCLK\_x pin) is used, the frame length must be aligned with a number equal to a power of 2, ranging from 8 to 256. When the master clock is not used (NODIV = 1), it is recommended to program the frame length to an value ranging from 8 to 256.  
These bits are meaningless and are not used in AC'97 or SPDIF audio block configuration.

### 43.5.13 SAI slot register (SAI\_BSLOTR)

Address offset: 0x0030

Reset value: 0x0000 0000

**Note:** This register has no meaning in AC'97 and SPDIF audio protocol.

|              |      |      |      |             |    |    |    |             |    |      |            |    |    |    |    |

| Res.         | Res. | Res. | Res. | NBSLOT[3:0] |    |    |    | SLOTSZ[1:0] |    | Res. | FBOFF[4:0] |    |    |    |    |
|              |      |      |      | rw          | rw | rw | rw | rw          | rw |      | rw         | rw | rw | rw | rw |

Bits 31:16 **SLOTEN[15:0]**: Slot enable.

These bits are set and cleared by software.

Each SLOTEN bit corresponds to a slot position from 0 to 15 (maximum 16 slots).

0: Inactive slot.

1: Active slot.

The slot must be enabled when the audio block is disabled.

They are ignored in AC'97 or SPDIF mode.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:8 **NBSLOT[3:0]**: Number of slots in an audio frame.

These bits are set and cleared by software.

The value set in this bitfield represents the number of slots + 1 in the audio frame (including the number of inactive slots). The maximum number of slots is 16.

The number of slots must be even if FSDEF bit in the SAI\_xFRCR register is set.

The number of slots must be configured when the audio block is disabled.

They are ignored in AC'97 or SPDIF mode.

Bits 7:6 **SLOTSZ[1:0]**: Slot size

This bits is set and cleared by software.

The slot size must be higher or equal to the data size. If this condition is not respected, the behavior of the SAI is undetermined.

Refer to [Output data line management on an inactive slot](#) for information on how to drive SD line.

These bits must be set when the audio block is disabled.

They are ignored in AC'97 or SPDIF mode.

00: The slot size is equivalent to the data size (specified in DS[3:0] in the SAI\_xCR1 register).

01: 16-bit

10: 32-bit

11: Reserved

Bit 5 Reserved, must be kept at reset value.

Bits 4:0 **FBOFF[4:0]**: First bit offset

These bits are set and cleared by software.

The value set in this bitfield defines the position of the first data transfer bit in the slot. It represents an offset value. In transmission mode, the bits outside the data field are forced to 0. In reception mode, the extra received bits are discarded.

These bits must be set when the audio block is disabled.

They are ignored in AC'97 or SPDIF mode.

**43.5.14 SAI interrupt mask register (SAI\_BIM)**

Address offset: 0x0034

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |              |              |             |            |              |               |              |

| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | LFSDET<br>IE | AFSDETI<br>E | CNRDY<br>IE | FREQ<br>IE | WCKCFG<br>IE | MUTEDET<br>IE | OVRUDR<br>IE |
|      |      |      |      |      |      |      |      |      | rw           | rw           | rw          | rw         | rw           | rw            | rw           |

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **LFSDETIE**: Late frame synchronization detection interrupt enable.

This bit is set and cleared by software.

0: Interrupt is disabled

1: Interrupt is enabled

When this bit is set, an interrupt is generated if the LFSDET bit is set in the SAI\_xSR register.

This bit is meaningless in AC'97, SPDIF mode or when the audio block operates as a master.

Bit 5 **AFSDETIE**: Anticipated frame synchronization detection interrupt enable.

This bit is set and cleared by software.

0: Interrupt is disabled

1: Interrupt is enabled

When this bit is set, an interrupt is generated if the AFSDET bit in the SAI\_xSR register is set.

This bit is meaningless in AC'97, SPDIF mode or when the audio block operates as a master.

Bit 4 **CNRDYIE**: Codec not ready interrupt enable (AC'97).

This bit is set and cleared by software.

0: Interrupt is disabled

1: Interrupt is enabled

When the interrupt is enabled, the audio block detects in the slot 0 (tag0) of the AC'97 frame if the Codec connected to this line is ready or not. If it is not ready, the CNRDY flag in the SAI\_xSR register is set and an interrupt is generated.

This bit has a meaning only if the AC'97 mode is selected through PRTCFG[1:0] bits and the audio block is operates as a receiver.

Bit 3 **FREQIE**: FIFO request interrupt enable.

This bit is set and cleared by software.

0: Interrupt is disabled

1: Interrupt is enabled

When this bit is set, an interrupt is generated if the FREQ bit in the SAI\_xSR register is set.

Since the audio block defaults to operate as a transmitter after reset, the MODE bit must be configured before setting FREQIE to avoid a parasitic interrupt in receiver mode,

Bit 2 **WCKCFGIE**: Wrong clock configuration interrupt enable.

This bit is set and cleared by software.

0: Interrupt is disabled

1: Interrupt is enabled

This bit is taken into account only if the audio block is configured as a master (MODE[1] = 0) and NODIV = 0.

It generates an interrupt if the WCKCFG flag in the SAI\_xSR register is set.

*Note: This bit is used only in Free protocol mode and is meaningless in other modes.*

Bit 1 **MUTEDETIE**: Mute detection interrupt enable.

This bit is set and cleared by software.

0: Interrupt is disabled

1: Interrupt is enabled

When this bit is set, an interrupt is generated if the MUTEDET bit in the SAI\_xSR register is set.

This bit has a meaning only if the audio block is configured in receiver mode.

Bit 0 **OVRUDRIE**: Overrun/underrun interrupt enable.

This bit is set and cleared by software.

0: Interrupt is disabled

1: Interrupt is enabled

When this bit is set, an interrupt is generated if the OVRUDR bit in the SAI\_xSR register is set.

### 43.5.15 SAI status register (SAI\_BSR)

Address offset: 0x0038

Reset value: 0x0000 0008

| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22     | 21      | 20    | 19   | 18        | 17      | 16     |

| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | LFSDET | AFSDDET | CNRDY | FREQ | WCKCFG    | MUTEDET | OVRUDR |
|      |      |      |      |      |      |      |      |      | r      | r       | r     | r    | r         | r       | r      |

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:16 **FLVL[2:0]**: FIFO level threshold.

This bit is read only. The FIFO level threshold flag is managed only by hardware and its setting depends on SAI block configuration (transmitter or receiver mode).

000: FIFO empty (transmitter and receiver modes)

001:  $\text{FIFO} \leq \frac{1}{4}$  but not empty (transmitter mode),  $\text{FIFO} < \frac{1}{4}$  but not empty (receiver mode)

010:  $\frac{1}{4} < \text{FIFO} \leq \frac{1}{2}$  (transmitter mode),  $\frac{1}{4} \leq \text{FIFO} < \frac{1}{2}$  (receiver mode)

011:  $\frac{1}{2} < \text{FIFO} \leq \frac{3}{4}$  (transmitter mode),  $\frac{1}{2} \leq \text{FIFO} < \frac{3}{4}$  (receiver mode)

100:  $\frac{3}{4} < \text{FIFO}$  but not full (transmitter mode),  $\frac{3}{4} \leq \text{FIFO}$  but not full (receiver mode)

101: FIFO full (transmitter and receiver modes)

Others: Reserved

Bits 15:7 Reserved, must be kept at reset value.

Bit 6 **LFSDET**: Late frame synchronization detection.

This bit is read only.

0: No error.

1: Frame synchronization signal is not present at the right time.

This flag can be set only if the audio block is configured in slave mode.

It is not used in AC'97 or SPDIF mode.

It can generate an interrupt if LFSDETIE bit is set in the SAI\_xIM register.

This flag is cleared when the software sets bit CLFSDET in SAI\_xCLRFR register

Bit 5 **AFSDET**: Anticipated frame synchronization detection.

This bit is read only.

0: No error.

1: Frame synchronization signal is detected earlier than expected.

This flag can be set only if the audio block is configured in slave mode.

It is not used in AC'97 or SPDIF mode.

It can generate an interrupt if AFSDETIE bit is set in SAI\_xIM register.

This flag is cleared when the software sets CAFSDET bit in SAI\_xCLRFR register.

Bit 4 **CNRDY**: Codec not ready.

This bit is read only.

0: External AC'97 Codec is ready

1: External AC'97 Codec is not ready

This bit is used only when the AC'97 audio protocol is selected in the SAI\_xCR1 register and configured in receiver mode.

It can generate an interrupt if CNRDYIE bit is set in SAI\_xIM register.

This flag is cleared when the software sets CCNRDY bit in SAI\_xCLRFR register.

Bit 3 **FREQ**: FIFO request.

This bit is read only.

0: No FIFO request.

1: FIFO request to read or to write the SAI\_xDR.

The request depends on the audio block configuration:

- If the block is configured in transmission mode, the FIFO request is related to a write request operation in the SAI\_xDR.

- If the block configured in reception, the FIFO request related to a read request operation from the SAI\_xDR.

This flag can generate an interrupt if FREQIE bit is set in SAI\_xIM register.

Bit 2 **WCKCFG**: Wrong clock configuration flag.

This bit is read only.

0: Clock configuration is correct

1: Clock configuration does not respect the rule concerning the frame length specification defined in [Section 43.3.6: Frame synchronization](#) (configuration of FRL[7:0] bit in the SAI\_xFRCR register)

This bit is used only when the audio block operates in master mode (MODE[1] = 0) and NODIV = 0. It can generate an interrupt if WCKCFGIE bit is set in SAI\_xIM register.

This flag is cleared when the software sets CWCKCFG bit in SAI\_xCLRFR register.

Bit 1 **MUTEDET**: Mute detection.

This bit is read only.

0: No MUTE detection on the SD input line

1: MUTE value detected on the SD input line (0 value) for a specified number of consecutive audio frame

This flag is set if consecutive 0 values are received in each slot of a given audio frame and for a consecutive number of audio frames (set in the MUTEcnt bit in the SAI\_xCR2 register).

It can generate an interrupt if MUTEDETIE bit is set in SAI\_xIM register.

This flag is cleared when the software sets bit CMUTEDET in the SAI\_xCLRFR register.

Bit 0 **OVRUDR**: Overrun / underrun.

This bit is read only.

0: No overrun/underrun error.

1: Overrun/underrun error detection.

The overrun and underrun conditions can occur only when the audio block is configured as a receiver and a transmitter, respectively.

It can generate an interrupt if OVRUDRIE bit is set in SAI\_xIM register.

This flag is cleared when the software sets COVRUDR bit in SAI\_xCLRFR register.

### 43.5.16 SAI clear flag register (SAI\_BCLRFR)

Address offset: 0x003C

Reset value: 0x0000 0000

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **CLFSDET**: Clear late frame synchronization detection flag.

This bit is write only.

Programming this bit to 1 clears the LFSDET flag in the SAI\_xSR register.

This bit is not used in AC'97 or SPDIF mode

Reading this bit always returns the value 0.

Bit 5 **CAFSDET**: Clear anticipated frame synchronization detection flag.

This bit is write only.

Programming this bit to 1 clears the AFSDET flag in the SAI\_xSR register.

It is not used in AC'97 or SPDIF mode.

Reading this bit always returns the value 0.

Bit 4 **CCNRDY**: Clear Codec not ready flag.

This bit is write only.

Programming this bit to 1 clears the CNRDY flag in the SAI\_xSR register.

This bit is used only when the AC'97 audio protocol is selected in the SAI\_xCR1 register.

Reading this bit always returns the value 0.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **WCKCFG**: Clear wrong clock configuration flag.

This bit is write only.

Programming this bit to 1 clears the WCKCFG flag in the SAI\_xSR register.

This bit is used only when the audio block is set as master (MODE[1] = 0) and NODIV = 0 in the SAI\_xCR1 register.

Reading this bit always returns the value 0.

Bit 1 **CMUTEDET**: Mute detection flag.

This bit is write only.

Programming this bit to 1 clears the MUTEDET flag in the SAI\_xSR register.

Reading this bit always returns the value 0.

Bit 0 **COVRUDR**: Clear overrun / underrun.

This bit is write only.

Programming this bit to 1 clears the OVRUDR flag in the SAI\_xSR register.

Reading this bit always returns the value 0.

### 43.5.17 SAI data register (SAI\_BDR)

Address offset: 0x0040

Reset value: 0x0000 0000

|             |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

| DATA[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw          | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:0 **DATA[31:0]**: Data

A write to this register loads the FIFO provided the FIFO is not full.

A read from this register empties the FIFO if the FIFO is not empty.

## 43.5.18 SAI register map

**Table 275. SAI register map and reset values**

Refer to [Section 2.2](#) for the register boundary addresses.

## 44 Single wire protocol master interface (SWPMI)

### 44.1 Introduction

The single wire protocol master interface (SWPMI) is the master interface corresponding to the contactless front-end (CLF) defined in the ETSI TS 102 613 technical specification.

The principle of the Single wire protocol (SWP) is based on the transmission of digital information in full duplex mode:

- S1 signal (from Master to Slave) is transmitted by a digital modulation (L or H) in the voltage domain (refer to [Figure 489: S1 signal coding](#)),
- S2 signal (from Slave to Master) is transmitted by a digital modulation (L or H) in the current domain (refer to [Figure 490: S2 signal coding](#)).

Figure 489. S1 signal coding

Figure 490. S2 signal coding

## 44.2 SWPMI main features

The SWPMI module main features are the following (see [Figure 44.3.3: SWP bus states](#)):

- Full-duplex communication mode
- Automatic SWP bus state management
- Automatic handling of Start of frame (SOF)
- Automatic handling of End of frame (EOF)
- Automatic handling of stuffing bits
- Automatic CRC-16 calculation and generation in transmission
- Automatic CRC-16 calculation and checking in reception
- 32-bit Transmit data register
- 32-bit Receive data register
- Multi software buffer mode for efficient DMA implementation and multi frame buffering
- Configurable bit-rate up to 2 Mbit/s
- Configurable interrupts
- CRC error, underrun, overrun flags
- Frame reception and transmission complete flags
- Slave resume detection flag
- Loopback mode for test purpose
- Embedded SWPMI\_IO transceiver compliant with ETSI TS 102 613 technical specification
- Dedicated mode to output SWPMI\_RX, SWPMI\_TX and SWPMI\_SUSPEND signals on GPIOs, in case of external transceiver connection

## 44.3 SWPMI functional description

### 44.3.1 SWPMI block diagram

Figure 491. SWPMI block diagram

Refer to the bit SWPMI1SEL in [Section 6.4.28: Peripherals independent clock configuration register \(RCC\\_CCIPR\)](#) to select the SWPCLK (SWPMI core clock source).

**Note:** In order to support the exit from Stop mode by a RESUME by slave, it is mandatory to select HSI16 for SWPCLK. If this feature is not required, PCLK1 can be selected, and SWPMI must be disabled before entering the Stop mode.

### 44.3.2 SWP initialization and activation

The initialization and activation will set the SWPMI\_IO state from low to high.

For Class B, i.e.  $V_{DD}$  is in the range [2.70 V to 3.30 V], the procedure is the following:

1. clear the SWP\_CLASS bit in SWPMI\_OR register,
2. configure SWPMI\_IO as alternate function (refer to [Section 8: General-purpose I/Os \(GPIO\)](#)) to enable the SWPMI\_IO transceiver,
3. wait for  $t_{SWPSTART}$  Max (refer to product datasheet),
4. set SWPACT bit in SWPMI\_CR register to ACTIVATE the SWP i.e. to move from DEACTIVATED to SUSPENDED.

For Class C, i.e.  $V_{DD}$  is in the range [1.62 V to 1.98 V], the procedure is the following:

1. set the SWP\_CLASS bit in SWPMI\_OR register,
2. configure SWPMI\_IO as alternate function (refer to [Section 8: General-purpose I/Os \(GPIO\)](#)) to enable the SWPMI\_IO transceiver,
3. set SWPACT bit in SWPMI\_CR register to ACTIVATE the SWP i.e. to move from DEACTIVATED to SUSPENDED.

### 44.3.3 SWP bus states

The SWP bus can have the following states: DEACTIVATED, SUSPENDED, ACTIVATED.

Several transitions are possible:

- ACTIVATE: transition from DEACTIVATED to SUSPENDED state,
- SUSPEND: transition from ACTIVATED to SUSPENDED state,
- RESUME by master: transition from SUSPENDED to ACTIVATED state initiated by the master,
- RESUME by slave: transition from SUSPENDED to ACTIVATED state initiated by the slave,
- DEACTIVATE: transition from SUSPENDED to DEACTIVATED state.

#### ACTIVATE

During and just after reset, the SWPMI\_IO is configured in analog mode. Refer to [Section 44.3.2: SWP initialization and activation](#) to activate the SWP bus.

#### SUSPEND

The SWP bus stays in the ACTIVATED state as long as there is a communication with the slave, either in transmission or in reception. The SWP bus switches back to the SUSPENDED state as soon as there is no more transmission or reception activity, after 7 idle bits.

#### RESUME by master

Once the SWPMI is enabled, the user can request a SWPMI frame transmission. The SWPMI first sends a transition sequence and 8 idle bits (RESUME by master) before starting the frame transmission. The SWP moves from the SUSPENDED to ACTIVATED state after the RESUME by master (refer to [Figure 492: SWP bus states](#)).

#### RESUME by slave

Once the SWPMI is enabled, the SWP can also move from the SUSPENDED to ACTIVATED state if the SWPMI receives a RESUME from the slave. The RESUME by slave sets the SRF flag in the SWPMI\_ISR register.

#### DEACTIVATE

##### Deactivate request

If no more communication is required, and if SWP is in the SUSPENDED mode, the user can request to switch the SWP to the DEACTIVATED mode by disabling the SWPMI peripheral. The software must set DEACT bit in the SWPMI\_CR register in order to request the DEACTIVATED mode. If no RESUME by slave is detected by SWPMI, the DEACTF flag is set in the SWPMI\_ISR register and the SWPACT bit is cleared in the SWPMI\_ICR register. In case a RESUME by slave is detected by the SWPMI while the software is setting DEACT bit, the SRF flag is set in the SWPMI\_ISR register, DEACTF is kept cleared, SWPACT is kept set and DEACT bit is cleared.

In order to activate SWP again, the software must clear DEACT bit in the SWPMI\_CR register before setting SWPACT bit.

### Deactivate mode

In order to switch the SWP to the DEACTIVATED mode immediately, ignoring any possible incoming RESUME by slave, the user must clear SWPACT bit in the SWPMI\_CR register.

**Note:** *In order to further reduce current consumption once SWPACT bit is cleared, configure the SWPMI\_IO port as output push pull low in GPIO controller (refer to [Section 8: General-purpose I/Os \(GPIO\)](#)).*

**Figure 492. SWP bus states**

#### 44.3.4 SWPMI\_IO (internal transceiver) bypass

A SWPMI\_IO (transceiver), compliant with ETSI TS 102 613 technical specification, is embedded in the microcontroller. Nevertheless, this is possible to bypass it by setting SWP\_TBYP bit in SWPMI\_OR register. In this case, the SWPMI\_IO is disabled and the SWPMI\_RX, SWPMI\_TX and SWPMI\_SUSPEND signals are available as alternate functions on three GPIOs (refer to “Pinouts and pin description” in product datasheet). This configuration is selected to connect an external transceiver.

#### 44.3.5 SWPMI bit rate

The bit rate must be set in the SWPMI\_BRR register, according to the following formula:

$$F_{\text{SWP}} = F_{\text{SWPCLK}} / ((\text{BR}[5:0] + 1) \times 4)$$

**Note:** *The maximum bitrate is 2 Mbit/s.*

### 44.3.6 SWPMI frame handling

The SWP frame is composed of a Start of frame (SOF), a Payload from 1 to 30 bytes, a 16-bit CRC and an End of frame (EOF) (Refer to [Figure 493: SWP frame structure](#)).

Figure 493. SWP frame structure

The SWPMI embeds one 32-bit data register for transmission (SWPMI\_TDR), and one 32-bit data register for reception (SWPMI\_RDR).

In transmission, the SOF insertion, the CRC calculation and insertion, and the EOF insertion are managed automatically by the SWPMI. The user only has to provide the Payload content and size. A frame transmission starts as soon as data is written into the SWPMI\_TDR register. Dedicated flags indicate an empty transmit data register and a complete frame transmission event.

In reception, the SOF deletion, the CRC calculation and checking, and the EOF deletion are managed automatically by the SWPMI. The user only has to read the Payload content and size. Dedicated flags indicate a full receive data register, a complete frame reception and possibly CRC error events.

The stuffing bits insertion (in transmission) and stuffing bits deletion (in reception) are managed automatically by the SWPMI core. These operations are transparent for the user.

### 44.3.7 Transmission procedure

Before starting any frame transmission, the user must activate the SWP. Refer to [Section 44.3.2: SWP initialization and activation](#).

There are several possible software implementations for a frame transmission: No software buffer mode, Single software buffer mode, and Multi software buffer mode.

The software buffer usage requires the use of a DMA channel to transfer data from the software buffer in the RAM memory to the transmit data register in the SWPMI peripheral.

#### No software buffer mode

This mode does not require the use of DMA. The SWP frame transmission handling is done by polling status flags in the main loop or inside the SWPMI interrupt routine. There is a 32-bit transmit data register (SWPMI\_TDR) in the SWPMI, thus writing to this register will trigger the transmission of up to 4 bytes.

The No software buffer mode is selected by clearing TXDMA bit in the SWPMI\_CR register.

The frame transmission is started by the first write to the SWPMI\_TDR register. The low significant byte of the first 32-bit word (bits [7:0]) written into the SWPMI\_TDR register indicates the number of data bytes in the payload, and the 3 other bytes of this word must

contain the first 3 bytes of the payload (bits [15:8] contain the first byte of the payload, bits [23:16] the second byte and bits [31:24] the third byte). Then, the following writes to the SWPMI\_TDR register will only contain the following payload data bytes, up to 4 for each write.

**Note:** *The low significant byte of the first 32-bit word written into the SWPMI\_TDR register is coding the number of data bytes in the payload. This number could be from 1 to 30. Any other value in the low significant byte will be ignored and the transmission will not start.*

Writing to the SWPMI\_TDR register will induce the following actions:

- Send the transition sequence and 8 idle bits (RESUME by master) if the SWP bus state is SUPENDED (this will not happen if the SWP bus state is already ACTIVATED),
- Send a Start of frame (SOF),
- Send the payload according to the SWPMI\_TRD register content. If the number of bytes in the payload is greater than 3, the SWPMI\_TDR needs to be refilled by software, each time the TXE flag in the SWPMI\_ISR register is set, and as long as the TXBEF flag is not set in the SWPMI\_ISR register,
- Send the 16-bit CRC, automatically calculated by the SWPMI core,
- Send an End of frame (EOF).

The TXE flag is cleared automatically when the software is writing to the SWPMI\_TDR register.

Once the complete frame is sent, provided that no other frame transmission has been requested (i.e. SWPMI\_TDR has not been written again after the TXBEF flag setting), TCF and SUSP flags are set in the SWPMI\_ISR register 7 idle bits after the EOF transmission, and an interrupt is generated if TCIE bit is set in the SWPMI\_IER register (refer to [Figure 494: SWPMI No software buffer mode transmission](#)).

**Figure 494. SWPMI No software buffer mode transmission**

If another frame transmission is requested before the end of the EOF transmission, the TCF flag is not set and the frame will be consecutive to the previous one, with only one idle bit in between (refer to [Figure 495: SWPMI No software buffer mode transmission, consecutive frames](#)).

**Figure 495. SWPMI No software buffer mode transmission, consecutive frames**

### Single software buffer mode

This mode allows to transmit a complete SWP frame without a CPU intervention, using the DMA. The DMA will refill the 32-bit SWPMI\_TDR register, and the software can poll the end of the frame transmission using the SWPMI\_TXBEF flag.

The Single software buffer mode is selected by setting TXDMA bit and clearing TXMODE bit in the SWPMI\_CR register.

The DMA channel or stream must be configured in following mode (refer to DMA section):

- memory to memory mode disabled,
- memory increment mode enabled,
- memory size set to 32-bit,
- peripheral size set to 32-bit,
- peripheral increment mode disabled,
- circular mode disabled,
- data transfer direction set to read from memory.
- the number of words to be transfered must be set according to the SWP frame length,
- the source address is the SWP frame buffer in RAM,
- the destination address is the SWPMI\_TDR register.

Then the user must:

1. Set TXDMA bit in the SWPMI\_CR register,
2. Set TXBEIE bit in the SWPMI\_IER register,
3. Fill the buffer in the RAM memory (with the number of data bytes in the payload on the least significant byte of the first word),
4. Enable stream or channel in DMA module to start DMA transfer and frame transmission.

A DMA request is issued by SWPMI when TXE flag in SWPMI\_ISR is set. The TXE flag is cleared automatically when the DMA is writing to the SWPMI\_TDR register.

In the SWPMI interrupt routine, the user must check TXBEF bit in the SWPMI\_ISR register. If it is set, and if another frame needs to be transmitted, the user must:

1. Disable stream or channel in DMA module
2. Update the buffer in the RAM memory with the content of the next frame to be sent
3. Configure the total number of words to be transferred in DMA module
4. Enable stream or channel in DMA module to start next frame transmission
5. Set CTXBEF bit in the SWPMI\_ICR register to clear the TXBEF flag

### Multi software buffer mode

This mode allows to work with several frame buffers in the RAM memory, in order to ensure a continuous transmission, keeping a very low CPU load, and allowing more latency for buffer update by software thanks to the DMA. The software can check the DMA counters at any time and update SWP frames accordingly in the RAM memory.

The Multi software buffer mode must be used in combination with DMA in circular mode.

Each transmission buffer in the RAM memory must have a fixed length of eight 32-bit words, whatever the number of bytes in the SWP frame payload. The transmission buffers in the RAM memory must be filled by the software, keeping an offset of 8 between two consecutive ones. The first data byte of the buffer is the number of bytes of the frame payload. See the buffer example in [Figure 496: SWPMI Multi software buffer mode transmission](#)

The Multi software buffer mode is selected by setting both TXDMA and TXMODE bits in SWPMI\_CR register.

For example, in order to work with 4 transmission buffers, the user must configure the DMA as follows:

The DMA channel or stream must be configured in following mode (refer to DMA section):

- memory to memory mode disabled,
- memory increment mode enabled,
- memory size set to 32-bit,
- peripheral size set to 32-bit,
- peripheral increment mode disabled,
- circular mode enabled,
- data transfer direction set to read from memory,
- the number of words to be transferred must be set to 32 (8 words per buffer),
- the source address is the buffer1 in RAM,
- the destination address is the SWPMI\_TDR register.

Then, the user must:

1. Set TXDMA in the SWPMI\_CR register
2. Set TXBEIE in the SWPMI\_IER register
3. Fill buffer1, buffer2, buffer3 and buffer4 in the RAM memory (with the number of data bytes in the payload on the least significant byte of the first word)
4. Enable stream or channel in DMA module to start DMA.

In the SWPMI interrupt routine, the user must check TXBEF bit in the SWPMI\_ISR register. If it is set, the user must set CTXBEF bit in SWPMI\_ICR register to clear TXBEF flag and the user can update buffer1 in the RAM memory.

In the next SWPMI interrupt routine occurrence, the user will update buffer2, and so on.

The Software can also read the DMA counter (number of data to transfer) in the DMA registers in order to retrieve the frame which has already been transferred from the RAM memory and transmitted. For example, if the software works with 4 transmission buffers, and if the DMA counter equals 17, it means that two buffers are ready for updating in the RAM area. This is useful in case several frames are sent before the software can handle the SWPMI interrupt. If this happens, the software will have to update several buffers.

When there are no more frames to transmit, the user must disable the circular mode in the DMA module. The transmission will stop at the end of the buffer4 transmission.

If the transmission needs to stop before (for example at the end of buffer2), the user must set the low significant byte of the first word to 0 in buffer3 and buffer4.

TXDMA bit in the SWPMI\_CR register will be cleared by hardware as soon as the number of data bytes in the payload is read as 0 in the least significant byte of the first word.

**Figure 496. SWPMI Multi software buffer mode transmission**

### 44.3.8 Reception procedure

Before starting any frame reception, the user must activate the SWP (refer to [Section 44.3.2: SWP initialization and activation](#)).

Once SWPACT bit is set in the SWPMI\_CR register, a RESUME from slave state sets the SRF flag in the SWPMI\_ISR register and automatically enables the SWPMI for the frame reception.

If the SWP bus is already in the ACTIVATED state (for example because a frame transmission is ongoing), the SWPMI core does not need any RESUME by slave state, and the reception can take place immediately.

There are several possible software implementations for a frame reception:

- No software buffer mode,
- Single software buffer mode,
- Multi software buffer mode.

The software buffer usage requires the use of a DMA channel to transfer data from the receive data register in the SWPMI peripheral to the software buffer in the RAM memory.

#### No software buffer mode

This mode does not require the use of DMA. The SWP frame reception handling is done by polling status flags in the main loop or inside the SWPMI interrupt routine. There is a 32-bit receive data register (SWPMI\_RDR) in the SWPMI, allowing to receive up to 4 bytes before reading this register.

The No software buffer mode is selected by resetting RXDMA bit in the SWPMI\_CR register.

Once a Start of frame (SOF) is received, the following bytes (payload) are stored in the SWPMI\_RDR register. Once the SWPMI\_RDR is full, the RXNE flag is set in SWPMI\_ISR and an interrupt is generated if RIE bit is set in SWPMI\_IER register. The user can read the SWPMI\_RDR register and the RXNE flag is cleared automatically when the software is reading the SWPMI\_RDR register.

Once the complete frame has been received, including the CRC and the End of frame (EOF), both RXNE and RXBFF flags are set in the SWPMI\_ISR register. The user must read the last byte(s) of the payload in the SWPMI\_RDR register and set CRXBFF flag in SWPMI\_ICR in order to clear the RXBFF flag. The number of data bytes in the payload is available in the SWPMI\_RFL register. Again, the RXNE flag is reset automatically when the software is reading the SWPMI\_RDR register (refer to [Figure 497: SWPMI No software buffer mode reception](#)).

Reading the SWPMI\_RDR register while RXNE is cleared will return 0.

Figure 497. SWPMI No software buffer mode reception

### Single software buffer mode

This mode allows to receive a complete SWP frame without any CPU intervention using the DMA. The DMA transfers received data from the 32-bit SWPMI\_RDR register to the RAM memory, and the software can poll the end of the frame reception using the SWPMI\_RBFF flag.

The Single software buffer mode is selected by setting RXDMA bit and clearing RXMODE bit in the SWPMI\_CR register.

The DMA must be configured as follows:

The DMA channel or stream must be configured in following mode (refer to DMA section):

- memory to memory mode disabled,
- memory increment mode enabled,
- memory size set to 32-bit,
- peripheral size set to 32-bit,
- peripheral increment mode disabled,
- circular mode disabled,
- data transfer direction set to read from peripheral,
- the number of words to be transfered must be set to 8,
- the source address is the SWPMI\_RDR register,
- the destination address is the SWP frame buffer in RAM.

Then the user must:

1. Set RXDMA bit in the SWPMI\_CR register
2. Set RXBFIE bit in the SWPMI\_IER register
3. Enable stream or channel in DMA module.

A DMA request is issued by SWPMI when RXNE flag is set in SWPMI\_ISR. The RXNE flag is cleared automatically when the DMA is reading the SWPMI\_RDR register.

In the SWPMI interrupt routine, the user must check RXBFF bit in the SWPMI\_ISR register. If it is set, the user must:

1. Disable stream or channel in DMA module
2. Read the number of bytes in the received frame payload in the SWPMI\_RFL register
3. Read the frame payload in the RAM buffer
4. Enable stream or channel in DMA module
5. Set CRXBFF bit in the SWPMI\_ICR register to clear RXBFF flag (refer to [Figure 498: SWPMI single software buffer mode reception](#)).

**Figure 498. SWPMI single software buffer mode reception**

### Multi software buffer mode

This mode allows to work with several frame buffers in the RAM memory, in order to ensure a continuous reception, keeping a very low CPU load, using the DMA. The frame payloads are stored in the RAM memory, together with the frame status flags. The software can check the DMA counters and status flags at any time to handle the received SWP frames in the RAM memory.

The Multi software buffer mode must be used in combination with the DMA in circular mode.

The Multi software buffer mode is selected by setting both RXDMA and RXMODE bits in SWPMI\_CR register.

In order to work with  $n$  reception buffers in RAM, the DMA channel or stream must be configured in following mode (refer to DMA section):

- memory to memory mode disabled,
- memory increment mode enabled,
- memory size set to 32-bit,
- peripheral size set to 32-bit,
- peripheral increment mode disabled,
- circular mode enabled,
- data transfer direction set to read from peripheral,
- the number of words to be transferred must be set to  $8 \times n$  (8 words per buffer),
- the source address is the SWPMI\_TDR register,
- the destination address is the buffer1 address in RAM

Then the user must:

1. Set RXDMA in the SWPMI\_CR register
2. Set RXBFIE in the SWPMI\_IER register
3. Enable stream or channel in the DMA module.

In the SWPMI interrupt routine, the user must check RXBFF in the SWPMI\_ISR register. If it is set, the user must set CRXBFF bit in the SWPMI\_ICR register to clear RXBFF flag and the user can read the first frame payload received in the first buffer (at the RAM address set in DMA2\_CMAR1).

The number of data bytes in the payload is available in bits [23:16] of the last 8th word.

In the next SWPMI interrupt routine occurrence, the user will read the second frame received in the second buffer (address set in DMA2\_CMAR1 + 8), and so on (refer to [Figure 499: SWPMI Multi software buffer mode reception](#)).

In case the application software cannot ensure to handle the SWPMI interrupt before the next frame reception, each buffer status is available in the most significant byte of the 8th buffer word:

- The CRC error flag (equivalent to RXBERF flag in the SWPMI\_ISR register) is available in bit 24 of the 8th word. Refer to [Section 44.3.9: Error management](#) for an CRC error description.
- The receive overrun flag (equivalent to RXOVRF flag in the SWPMI\_ISR register) is available in bit 25 of the 8th word. Refer to [Section 44.3.9: Error management](#) for an overrun error description.
- The receive buffer full flag (equivalent to RXBFF flag in the SWPMI\_ISR register) is available in bit 26 of the 8th word.

In case of a CRC error, both RXBFF and RXBERF flags are set, thus bit 24 and bit 26 are set.

In case of an overrun, an overrun flag is set, thus bit 25 is set. The receive buffer full flag is set only in case of an overrun during the last word reception; then, both bit 25 and bit 26 are set for the current and the next frame reception.

The software can also read the DMA counter (number of data to transfer) in the DMA registers in order to retrieve the frame which has already been received and transferred into the RAM memory through DMA. For example, if the software works with 4 reception buffers,

and if the DMA counter equals 17, it means that two buffers are ready for reading in the RAM area.

In Multi software buffer reception mode, if the software is reading bits 24, 25 and 26 of the 8th word, it does not need to clear RXBERF, RXOVRF and RXBFF flags after each frame reception.

**Figure 499. SWPMI Multi software buffer mode reception**

### 44.3.9 Error management

#### Underrun during payload transmission

During the transmission of the frame payload, a transmit underrun is indicated by the TXUNRF flag in the SWPMI\_ISR register. An interrupt is generated if TXBUNREIE bit is set in the SWPMI\_IER register.

If a transmit underrun occurs, the SWPMI stops the payload transmission and sends a corrupted CRC (the first bit of the first CRC byte sent is inverted), followed by an EOF. If DMA is used, TXDMA bit in the SWPMI\_CR register is automatically cleared.

Any further write to the SWPMI\_TDR register while TXUNRF is set will be ignored. The user must set CTXUNRF bit in the SWPMI\_ICR register to clear TXUNRF flag.

### Overrun during payload reception

During the reception of the frame payload, a receive overrun is indicated by RXOVRF flag in the SWPMI\_ISR register. If a receive overrun occurs, the SWPMI does not update SWPMI\_RDR with the incoming data. The incoming data will be lost.

The reception carries on up to the EOF and, if the overrun condition disappears, the RXBFF flag is set. When RXBFF flag is set, the user can check the RXOVRF flag. The user must set CRXOVRF bit in the SWPMI\_ICR register to clear RXBOVRF flag.

If the user wants to detect the overrun immediately, RXBOVREIE bit in the SWPMI\_IER register can be set in order to generate an interrupt as soon as the overrun occurs.

The RXOVRF flag is set at the same time as the RXNE flag, two SWPMI\_RDR reads after the overrun event occurred. It indicates that at least one received byte was lost, and the loaded word in SWPMI\_RDR contains the bytes received just before the overrun.

In Multi software buffer mode, if RXOVRF flag is set for the last word of the received frame, then the overrun bit (bit 25 of the 8th word) is set for both the current and the next frame.

### CRC error during payload reception

Once the two CRC bytes have been received, if the CRC is wrong, the RXBERF flag in the SWPMI\_ISR register is set after the EOF reception. An interrupt is generated if RXBEIE bit in the SWPMI\_IER register is set (refer to [Figure 500: SWPMI single buffer mode reception with CRC error](#)). The user must set CRXBERF bit in SWPMI\_ICR to clear RXBERF flag.

**Figure 500. SWPMI single buffer mode reception with CRC error**

### Missing or corrupted stuffing bit during payload reception

When a stuffing bit is missing or is corrupted in the payload, RXBERF and RXBFF flags are set in SWPMI\_ISR after the EOF reception.

### Corrupted EOF reception

Once an SOF has been received, the SWPMI accumulates the received bytes until the reception of an EOF (ignoring any possible SOF). Once an EOF has been received, the SWPMI is ready to start a new frame reception and waits for an SOF.

In case of a corrupted EOF, RXBERF and RXBFF flags will be set in the SWPMI\_ISR register after the next EOF reception.

*Note: In case of a corrupted EOF reception, the payload reception carries on, thus the number of bytes in the payload might get the value 31 if the number of received bytes is greater than 30. The number of bytes in the payload is read in the SWPMI\_RFL register or in bits [23:16] of the 8th word of the buffer in the RAM memory, depending on the operating mode.*

#### 44.3.10 Loopback mode

The loopback mode can be used for test purposes. The user must set LPBK bit in the SWPMI\_CR register in order to enable the loopback mode.

When the loopback mode is enabled, SWPMI\_TX and SWPMI\_RX signals are connected together. As a consequence, all frames sent by the SWPMI will be received back.

## 44.4 SWPMI low-power modes

**Table 276. Effect of low-power modes on SWPMI**

| Mode            | Description                                                                                                                                                                                                                   |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Sleep           | No effect. SWPMI interrupts cause the device to exit the Sleep mode.                                                                                                                                                          |
| Low-power run   | No effect.                                                                                                                                                                                                                    |
| Low-power sleep | No effect. SWPMI interrupts cause the device to exit the Low-power sleep mode.                                                                                                                                                |
| Stop 0 / Stop 1 | SWPMI registers content is kept. A RESUME from SUSPENDED mode issued by the slave can wake up the device from Stop 0 and Stop 1 modes if the SWPCLK is HSI16 (refer to <a href="#">Section 44.3.1: SWPMI block diagram</a> ). |
| Stop 2          | SWPMI registers content is kept. SWPMI must be disabled before entering Stop 2.                                                                                                                                               |
| Standby         | The SWPMI peripheral is powered down and must be reinitialized after exiting Standby or Shutdown mode.                                                                                                                        |
| Shutdown        |                                                                                                                                                                                                                               |

## 44.5 SWPMI interrupts

All SWPMI interrupts are connected to the NVIC.

To enable the SWPMI interrupt, the following sequence is required:

1. Configure and enable the SWPMI interrupt channel in the NVIC
2. Configure the SWPMI to generate SWPMI interrupts (refer to the SWPMI\_IER register).

**Table 277. Interrupt control bits**

| Interrupt event                  | Event flag | Enable control bit | Exit the Sleep mode | Exit the Stop mode | Exit the Standby mode |
