1. If HSI16 is selected for SWPCLK.

## 44.6 SWPMI registers

Refer to [Section 1.2](#) of the reference manual for a list of abbreviations used in register descriptions.

The peripheral registers can only be accessed by words (32-bit).

### 44.6.1 SWPMI configuration/control register (SWPMI\_CR)

Address offset: 0x00

Reset value: 0x0000 0000

|      |      |      |      |      |       |      |      |      |      |            |      |            |            |       |       |
|------|------|------|------|------|-------|------|------|------|------|------------|------|------------|------------|-------|-------|
| 31   | 30   | 29   | 28   | 27   | 26    | 25   | 24   | 23   | 22   | 21         | 20   | 19         | 18         | 17    | 16    |
| Res. | Res. | Res. | Res. | Res. | Res.  | Res. | Res. | Res. | Res. | Res.       | Res. | Res.       | Res.       | Res.  | Res.  |
|      |      |      |      |      |       |      |      |      |      |            |      |            |            |       |       |
| 15   | 14   | 13   | 12   | 11   | 10    | 9    | 8    | 7    | 6    | 5          | 4    | 3          | 2          | 1     | 0     |
| Res. | Res. | Res. | Res. | Res. | DEACT | Res. | Res. | Res. | Res. | SWP<br>ACT | LPBK | TXMOD<br>E | RXMO<br>DE | TXDMA | RXDMA |
|      |      |      |      |      | rw    |      |      |      |      | rw         | rw   | rw         | rw         | rw    | rw    |

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **DEACT**: Single wire protocol master interface deactivate

This bit is used to request the SWP DEACTIVATED state. Setting this bit has the same effect as clearing the SWPACT, except that a possible incoming RESUME by slave will keep the SWP in the ACTIVATED state.

Bits 9:6 Reserved, must be kept at reset value.

Bit 5 **SWPACT**: Single wire protocol master interface activate

This bit is used to activate the SWP bus (refer to [Section 44.3.2: SWP initialization and activation](#)).

0: SWPMI\_IO is pulled down to ground, SWP bus is switched to DEACTIVATED state

1: SWPMI\_IO is released, SWP bus is switched to SUSPENDED state

To be able to set SWPACT bit, DEACT bit must have been cleared previously.

Bit 4 **LPBK**: Loopback mode enable

This bit is used to enable the loopback mode

0: Loopback mode is disabled

1: Loopback mode is enabled

*Note: This bit cannot be written while SWPACT bit is set.*

Bit 3 **TXMODE**: Transmission buffering mode

This bit is used to choose the transmission buffering mode. This bit is relevant only when TXDMA bit is set (refer to [Table 278: Buffer modes selection for transmission/reception](#)).

0: SWPMI is configured in Single software buffer mode for transmission

1: SWPMI is configured in Multi software buffer mode for transmission.

*Note: This bit cannot be written while SWPACT bit is set.*

Bit 2 **RXMODE**: Reception buffering mode

This bit is used to choose the reception buffering mode. This bit is relevant only when TXDMA bit is set (refer to [Table 278: Buffer modes selection for transmission/reception](#)).

0: SWPMI is configured in Single software buffer mode for reception

1: SWPMI is configured in Multi software buffer mode for reception.

*Note: This bit cannot be written while SWPACT bit is set.*

Bit 1 **TXDMA**: Transmission DMA enable

This bit is used to enable the DMA mode in transmission

0: DMA is disabled for transmission

1: DMA is enabled for transmission

*Note: TXDMA is automatically cleared if the payload size of the transmitted frame is given as 0x00 (in the least significant byte of TDR for the first word of a frame). TXDMA is also automatically cleared on underrun events (when TXUNRF flag is set in the SWP\_ISR register)*

Bit 0 **RXDMA**: Reception DMA enable

This bit is used to enable the DMA mode in reception

0: DMA is disabled for reception

1: DMA is enabled for reception

**Table 278. Buffer modes selection for transmission/reception**

| Buffer mode   | No software buffer | Single software buffer | Multi software buffer |
|---------------|--------------------|------------------------|-----------------------|
| RXMODE/TXMODE | x                  | 0                      | 1                     |
| RXDMA/TXDMA   | 0                  | 1                      | 1                     |

## 44.6.2 SWPMI Bitrate register (SWPMI\_BRR)

Address offset: 0x04

Reset value: 0x0000 0001

|      |      |      |      |      |      |      |      |      |      |         |      |      |      |      |      |
|------|------|------|------|------|------|------|------|------|------|---------|------|------|------|------|------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21      | 20   | 19   | 18   | 17   | 16   |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.    | Res. | Res. | Res. | Res. | Res. |
|      |      |      |      |      |      |      |      |      |      |         |      |      |      |      |      |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5       | 4    | 3    | 2    | 1    | 0    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | BR[5:0] |      |      |      |      |      |
|      |      |      |      |      |      |      |      |      |      | rw      | rw   | rw   | rw   | rw   | rw   |

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:0 **BR[5:0]**: Bitrate prescaler

This field must be programmed to set SWP bus bitrate, taking into account the  $F_{SWPCLK}$  programmed in the RCC (Reset and Clock Control), according to the following formula:

$$F_{SWP} = F_{SWPCLK} / ((BR[5:0] + 1) \times 4)$$

*Note: The programmed bitrate must stay within the following range: from 100 kbit/s up to 2 Mbit/s.*

*BR[5:0] cannot be written while SWPACT bit is set in the SWPMI\_CR register.*

### 44.6.3 SWPMI Interrupt and Status register (SWPMI\_ISR)

Address offset: 0x0C

Reset value: 0x0000 02C2

|      |      |      |      |      |            |      |      |      |      |      |            |            |            |       |       |
|------|------|------|------|------|------------|------|------|------|------|------|------------|------------|------------|-------|-------|
| 31   | 30   | 29   | 28   | 27   | 26         | 25   | 24   | 23   | 22   | 21   | 20         | 19         | 18         | 17    | 16    |
| Res. | Res. | Res. | Res. | Res. | Res.       | Res. | Res. | Res. | Res. | Res. | Res.       | Res.       | Res.       | Res.  | Res.  |
|      |      |      |      |      |            |      |      |      |      |      |            |            |            |       |       |
| 15   | 14   | 13   | 12   | 11   | 10         | 9    | 8    | 7    | 6    | 5    | 4          | 3          | 2          | 1     | 0     |
| Res. | Res. | Res. | Res. | Res. | DEACT<br>F | SUSP | SRF  | TCF  | TXE  | RXNE | TXUNR<br>F | RXOVR<br>F | RXBER<br>F | TXBEF | RXBFF |
|      |      |      |      |      | r          | r    | r    | r    | r    | r    | r          | r          | r          | r     | r     |

Bits 31:11 Reserved, must be kept at reset value.

**Bit 10 DEACTF:** DEACTIVATED flag

This bit is a status flag, acknowledging the request to enter the DEACTIVATED mode.

0: SWP bus is in ACTIVATED or SUSPENDED state

1: SWP bus is in DEACTIVATED state

If a RESUME by slave state is detected by the SWPMI while DEACT bit is set by software, the SRF flag will be set, DEACTF will not be set and SWP will move in ACTIVATED state.

**Bit 9 SUSP:** SUSPEND flag

This bit is a status flag, reporting the SWP bus state

0: SWP bus is in ACTIVATED state

1: SWP bus is in SUSPENDED or DEACTIVATED state

**Bit 8 SRF:** Slave resume flag

This bit is set by hardware to indicate a RESUME by slave detection. It is cleared by software, writing 1 to CSRF bit in the SWPMI\_ICR register.

0: No Resume by slave state detected

1: A Resume by slave state has been detected during the SWP bus SUSPENDED state

**Bit 7 TCF:** Transfer complete flag

This flag is set by hardware as soon as both transmission and reception are completed and SWP is switched to the SUSPENDED state. It is cleared by software, writing 1 to CTCF bit in the SWPMI\_ICR register.

0: Transmission or reception is not completed

1: Both transmission and reception are completed and SWP is switched to the SUSPENDED state

**Bit 6 TXE:** Transmit data register empty

This flag indicates the transmit data register status

0: Data written in transmit data register SWPMI\_TDR is not transmitted yet

1: Data written in transmit data register SWPMI\_TDR has been transmitted and SWPMI\_TDR can be written to again

**Bit 5 RXNE:** Receive data register not empty

This flag indicates the receive data register status

0: Data is not received in the SWPMI\_RDR register

1: Received data is ready to be read in the SWPMI\_RDR register

**Bit 4 TXUNRF:** Transmit underrun error flag

This flag is set by hardware to indicate an underrun during the payload transmission i.e. SWPMI\_TDR has not been written in time by the software or the DMA. It is cleared by software, writing 1 to the CTXUNRF bit in the SWPMI\_ICR register.

0: No underrun error in transmission

1: Underrun error in transmission detected

**Bit 3 RXOVRF:** Receive overrun error flag

This flag is set by hardware to indicate an overrun during the payload reception, i.e.

SWPMI\_RDR has not been read in time by the software or the DMA. It is cleared by software, writing 1 to CRXOVRF bit in the SWPMI\_ICR register.

0: No overrun in reception

1: Overrun in reception detected

**Bit 2 RXBERF:** Receive CRC error flag

This flag is set by hardware to indicate a CRC error in the received frame. It is set synchronously with RXBFF flag. It is cleared by software, writing 1 to CRXBERF bit in the SWPMI\_ICR register.

0: No CRC error in reception

1: CRC error in reception detected

**Bit 1 TXBEF:** Transmit buffer empty flag

This flag is set by hardware to indicate that no more SWPMI\_TDR update is required to complete the current frame transmission. It is cleared by software, writing 1 to CTXBEF bit in the SWPMI\_ICR register.

0: Frame transmission buffer not yet emptied

1: Frame transmission buffer has been emptied

**Bit 0 RXBFF:** Receive buffer full flag

This flag is set by hardware when the final word for the frame under reception is available in SWPMI\_RDR. It is cleared by software, writing 1 to CRXBFF bit in the SWPMI\_ICR register.

0: The last word of the frame under reception has not yet arrived in SWPMI\_RDR

1: The last word of the frame under reception has arrived in SWPMI\_RDR

**44.6.4 SWPMI Interrupt Flag Clear register (SWPMI\_ICR)**

Address offset: 0x10

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |       |       |      |      |         |         |         |        |        |

Bits 31:9 Reserved, must be kept at reset value

Bit 8 **CSRF**: Clear slave resume flag

Writing 1 to this bit clears the SRF flag in the SWPMI\_ISR register

Writing 0 to this bit does not have any effect

Bit 7 **CTCF**: Clear transfer complete flag

Writing 1 to this bit clears the TCF flag in the SWPMI\_ISR register

Writing 0 to this bit does not have any effect

Bits 6:5 Reserved, must be kept at reset value.

Bit 4 **CTXUNRF**: Clear transmit underrun error flag

Writing 1 to this bit clears the TXUNRF flag in the SWPMI\_ISR register

Writing 0 to this bit does not have any effect

Bit 3 **CRXOVRF**: Clear receive overrun error flag

Writing 1 to this bit clears the RXBOCREF flag in the SWPMI\_ISR register

Writing 0 to this bit does not have any effect

Bit 2 **CRXBERF**: Clear receive CRC error flag

Writing 1 to this bit clears the RXBERF flag in the SWPMI\_ISR register

Writing 0 to this bit does not have any effect

Bit 1 **CTXBEF**: Clear transmit buffer empty flag

Writing 1 to this bit clears the TXBEF flag in the SWPMI\_ISR register

Writing 0 to this bit does not have any effect

Bit 0 **CRXBFF**: Clear receive buffer full flag

Writing 1 to this bit clears the RXBFF flag in the SWPMI\_ISR register

Writing 0 to this bit does not have any effect

#### 44.6.5 SWPMI Interrupt Enable register (SWPMI\_IER)

Address offset: 0x14

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |      |      |              |              |            |            |        |

Bits 31:9 Reserved, must be kept at reset value

Bit 8 **SRIE**: Slave resume interrupt enable

0: Interrupt is inhibited

1: An SWPMI interrupt is generated whenever SRF flag is set in the SWPMI\_ISR register

Bit 7 **TCIE**: Transmit complete interrupt enable

0: Interrupt is inhibited

1: An SWPMI interrupt is generated whenever TCF flag is set in the SWPMI\_ISR register

- Bit 6 **TIE**: Transmit interrupt enable  
 0: Interrupt is inhibited  
 1: An SWPMI interrupt is generated whenever TXE flag is set in the SWPMI\_ISR register
- Bit 5 **RIE**: Receive interrupt enable  
 0: Interrupt is inhibited  
 1: An SWPMI interrupt is generated whenever RXNE flag is set in the SWPMI\_ISR register
- Bit 4 **TXUNREIE**: Transmit underrun error interrupt enable  
 0: Interrupt is inhibited  
 1: An SWPMI interrupt is generated whenever TXBUNRF flag is set in the SWPMI\_ISR register
- Bit 3 **RXOVREIE**: Receive overrun error interrupt enable  
 0: Interrupt is inhibited  
 1: An SWPMI interrupt is generated whenever RXBOVRF flag is set in the SWPMI\_ISR register
- Bit 2 **RXBEIE**: Receive CRC error interrupt enable  
 0: Interrupt is inhibited  
 1: An SWPMI interrupt is generated whenever RXBERF flag is set in the SWPMI\_ISR register
- Bit 1 **TXBEIE**: Transmit buffer empty interrupt enable  
 0: Interrupt is inhibited  
 1: An SWPMI interrupt is generated whenever TXBEF flag is set in the SWPMI\_ISR register
- Bit 0 **RXBFIIE**: Receive buffer full interrupt enable  
 0: Interrupt is inhibited  
 1: An SWPMI interrupt is generated whenever RXBFF flag is set in the SWPMI\_ISR register

Bits 31:5 Reserved, must be kept at reset value.

Bits 4:0 **RFL[4:0]**: Receive frame length

RFL[4:0] is the number of data bytes in the payload of the received frame. The two least significant bits RFL[1:0] give the number of relevant bytes for the last SWPMI\_RDR register read.

**44.6.7 SWPMI Transmit data register (SWPMI\_TDR)**

Address offset: 0x1C

Reset value: 0x0000 0000

|           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31        | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| TD[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| w         | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  |
| 15        | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| TD[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| w         | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  |

Bits 31:0 **TD[31:0]**: Transmit data

Contains the data to be transmitted.

Writing to this register triggers the SOF transmission or the next payload data transmission, and clears the TXE flag.

**44.6.8 SWPMI Receive data register (SWPMI\_RDR)**

Address offset: 0x20

Reset value: 0x0000 0000

|           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31        | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | SWP_CLASS | SWP_TBYP |
|      |      |      |      |      |      |      |      |      |      |      |      |      |      | rw        | rw       |

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **SWP\_CLASS**: SWP class selection

This bit is used to select the SWP class (refer to [Section 44.3.2: SWP initialization and activation](#)).

0: Class C: SWPMI\_IO uses directly VDD voltage to operate in class C.

This configuration must be selected when VDD is in the range [1.62 V to 1.98 V]

1: Class B: SWPMI\_IO uses an internal voltage regulator to operate in class B.

This configuration must be selected when VDD is in the range [2.70 V to 3.30 V]

Bit 0 **SWP\_TBYP**: SWP transceiver bypass

This bit is used to bypass the internal transceiver (SWPMI\_IO), and connect an external transceiver.

0: Internal transceiver is enabled. The external interface for SWPMI is SWPMI\_IO (SWPMI\_RX, SWPMI\_TX and SWPMI\_SUSPEND signals are not available on GPIOs)

1: Internal transceiver is disabled. SWPMI\_RX, SWPMI\_TX and SWPMI\_SUSPEND signals are available as alternate function on GPIOs. This configuration is selected to connect an external transceiver

## 44.6.10 SWPMI register map and reset value table

Table 279. SWPMI register map and reset values

| Offset | Register name | 31       | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   | 15   | 14   | 13   | 12   | 11   | 10     | 9    | 8    | 7    | 6    | 5        | 4        | 3       | 2       | 1      | 0         |          |  |

Refer to [Section 2.2 on page 75](#) for the register boundary addresses.

## 45 SD/SDIO/MMC card host interface (SDMMC)

### 45.1 SDMMC main features

The SD/SDIO MMC card host interface (SDMMC) provides an interface between the APB2 peripheral bus and MultiMediaCards (MMCs), SD memory cards and SDIO cards.

The MultiMediaCard system specifications are available through the MultiMediaCard Association website, published by the MMCA technical committee.

SD memory card and SD I/O card system specifications are available through the SD card Association website.

The SDMMC features include the following:

- Full compliance with *MultiMediaCard System Specification Version 4.2*. Card support for three different databus modes: 1-bit (default), 4-bit and 8-bit
- Full compatibility with previous versions of MultiMediaCards (forward compatibility)
- Full compliance with *SD Memory Card Specifications Version 2.0*
- Full compliance with *SD I/O Card Specification Version 2.0*: card support for two different databus modes: 1-bit (default) and 4-bit
- Data transfer up to 50 MHz for the 8 bit mode
- Data and command output enable signals to control external bidirectional drivers.

- Note:*
- 1 *The SDMMC does not have an SPI-compatible communication mode.*
  - 2 *The SD memory card protocol is a superset of the MultiMediaCard protocol as defined in the MultiMediaCard system specification V2.11. Several commands required for SD memory devices are not supported by either SD I/O-only cards or the I/O portion of combo cards. Some of these commands have no use in SD I/O devices, such as erase commands, and thus are not supported in the SDIO protocol. In addition, several commands are different between SD memory cards and SD I/O cards and thus are not supported in the SDIO protocol. For details refer to SD I/O card Specification Version 1.0.*

The MultiMediaCard/SD bus connects cards to the controller.

The current version of the SDMMC supports only one SD/SDIO/MMC4.2 card at any one time and a stack of MMC4.1 or previous.

### 45.2 SDMMC bus topology

Communication over the bus is based on command and data transfers.

The basic transaction on the MultiMediaCard/SD/SD I/O bus is the command/response transaction. These types of bus transaction transfer their information directly within the command or response structure. In addition, some operations have a data token.

Data transfers to/from SD/SDIO memory cards are done in data blocks. Data transfers to/from MMC are done data blocks or streams.

Figure 501. “No response” and “no data” operations

Figure 502. (Multiple) block read operation

Figure 503. (Multiple) block write operation

Note: The SDMMC will not send any data as long as the Busy signal is asserted (SDMMC\_D0 pulled low).

Figure 504. Sequential read operation

Figure 505. Sequential write operation

### 45.3 SDMMC functional description

The SDMMC consists of two parts:

- The SDMMC adapter block provides all functions specific to the MMC/SD/SD I/O card such as the clock generation unit, command and data transfer.
- The APB2 interface accesses the SDMMC adapter registers, and generates interrupt and DMA request signals.

Figure 506. SDMMC block diagram

By default SDMMC\_D0 is used for data transfer. After initialization, the host can change the databus width.

If a MultiMediaCard is connected to the bus, SDMMC\_D0, SDMMC\_D[3:0] or SDMMC\_D[7:0] can be used for data transfer. MMC V3.31 or previous, supports only 1 bit of data so only SDMMC\_D0 can be used.

If an SD or SD I/O card is connected to the bus, data transfer can be configured by the host to use SDMMC\_D0 or SDMMC\_D[3:0]. All data lines are operating in push-pull mode.

**SDMMC\_CMD** has two operational modes:

- Open-drain for initialization (only for MMCV3.31 or previous)
- Push-pull for command transfer (SD/SD I/O card MMC4.2 use push-pull drivers also for initialization)

**SDMMC\_CK** is the clock to the card: one bit is transferred on both command and data lines with each clock cycle.

The SDMMC uses two clock signals:

- SDMMC adapter clock SDMMCCLK = 50 MHz)
- APB2 bus clock (PCLK2)

PCLK2 and SDMMC\_CK clock frequencies must respect the following condition:

$$\text{Frequency(PCLK2)} > ((3 \times \text{Width}) / 32) \times \text{Frequency(SDMMC\_CK)}$$

The signals shown in [Table 280](#) are used on the MultiMediaCard/SD/SD I/O card bus.

**Table 280. SDMMC I/O definitions**

| Pin          | Direction     | Description                                                                                 |
|--------------|---------------|---------------------------------------------------------------------------------------------|
| SDMMC_CK     | Output        | MultiMediaCard/SD/SDIO card clock. This pin is the clock from host to card.                 |
| SDMMC_CMD    | Bidirectional | MultiMediaCard/SD/SDIO card command. This pin is the bidirectional command/response signal. |
| SDMMC_D[7:0] | Bidirectional | MultiMediaCard/SD/SDIO card data. These pins are the bidirectional databus.                 |

### 45.3.1 SDMMC adapter

Figure 507 shows a simplified block diagram of an SDMMC adapter.

Figure 507. SDMMC adapter

The SDMMC adapter is a multimedia/secure digital memory card bus master that provides an interface to a multimedia card stack or to a secure digital memory card. It consists of five subunits:

- Adapter register block
- Control unit
- Command path
- Data path
- Data FIFO

**Note:** The adapter registers and FIFO use the APB2 bus clock domain (PCLK2). The control unit, command path and data path use the SDMMC adapter clock domain (SDMMCCLK).

#### Adapter register block

The adapter register block contains all system registers. This block also generates the signals that clear the static flags in the multimedia card. The clear signals are generated when 1 is written into the corresponding bit location in the SDMMC Clear register.

#### Control unit

The control unit contains the power management functions and the clock divider for the memory card clock.

There are three power phases:

- power-off
- power-up
- power-on

Figure 508. Control unit

The control unit is illustrated in [Figure 508](#). It consists of a power management subunit and a clock management subunit.

The power management subunit disables the card bus output signals during the power-off and power-up phases.

The clock management subunit generates and controls the SDMMC\_CK signal. The SDMMC\_CK output can use either the clock divide or the clock bypass mode. The clock output is inactive:

- after reset
- during the power-off or power-up phases
- if the power saving mode is enabled and the card bus is in the Idle state (eight clock periods after both the command and data path subunits enter the Idle phase)

The clock management subunit controls SDMMC\_CK dephasing. When not in bypass mode the SDMMC command and data output are generated on the SDMMCCLK falling edge succeeding the rising edge of SDMMC\_CK. (SDMMC\_CK rising edge occurs on SDMMCCLK rising edge) when SDMMC\_CLKCR[13] bit is reset (NEGEDGE = 0). When SDMMC\_CLKCR[13] bit is set (NEGEDGE = 1) SDMMC command and data changed on the SDMMC\_CK falling edge.

When SDMMC\_CLKCR[10] is set (BYPASS = 1), SDMMC\_CK rising edge occurs on SDMMCCLK rising edge. The data and the command change on SDMMCCLK falling edge whatever NEGEDGE value.

The data and command responses are latched using SDMMC\_CK rising edge.

Figure 509. SDMMC\_CLK clock dephasing (BYPASS = 0)

### Command path

The command path unit sends commands to and receives responses from the cards.

Figure 510. SDMMC adapter command path

- Command path state machine (CPSM)
  - When the command register is written to and the enable bit is set, command transfer starts. When the command has been sent, the command path state machine (CPSM) sets the status flags and enters the Idle state if a response is not required. If a response is required, it waits for the response (see [Figure 511 on page 1554](#)). When the response is received, the received CRC code and the internally generated code are compared, and the appropriate status flags are set.

Figure 511. Command path state machine (SDMMC)

When the Wait state is entered, the command timer starts running. If the timeout is reached before the CPSM moves to the Receive state, the timeout flag is set and the Idle state is entered.

**Note:** The command timeout has a fixed value of 64 SDMMC\_CLK clock periods.

If the interrupt bit is set in the command register, the timer is disabled and the CPSM waits for an interrupt request from one of the cards. If a pending bit is set in the command register, the CPSM enters the Pend state, and waits for a CmdPend signal from the data path subunit. When CmdPend is detected, the CPSM moves to the Send state. This enables the data counter to trigger the stop command transmission.

**Note:** The CPSM remains in the Idle state for at least eight SDMMC\_CLK periods to meet the  $N_{CC}$  and  $N_{RC}$  timing constraints.  $N_{CC}$  is the minimum delay between two host commands, and  $N_{RC}$  is the minimum delay between the host command and the card response.

Figure 512. SDMMC command transfer

- Command format
  - Command: a command is a token that starts an operation. Command are sent from the host either to a single card (addressed command) or to all connected cards (broadcast command are available for MMC V3.31 or previous). Commands are transferred serially on the CMD line. All commands have a fixed length of 48 bits. The general format for a command token for MultiMediaCards, SD-Memory cards and SDIO-Cards is shown in [Table 281](#).  
The command path operates in a half-duplex mode, so that commands and responses can either be sent or received. If the CPSM is not in the Send state, the SDMMC\_CMD output is in the Hi-Z state, as shown in [Figure 512 on page 1555](#). Data on SDMMC\_CMD are synchronous with the rising edge of SDMMC\_CK. [Table 281](#) shows the command format.

Table 281. Command format

| Bit position | Width | Value | Description      |
|--------------|-------|-------|------------------|
| 47           | 1     | 0     | Start bit        |
| 46           | 1     | 1     | Transmission bit |
| [45:40]      | 6     | -     | Command index    |
| [39:8]       | 32    | -     | Argument         |
| [7:1]        | 7     | -     | CRC7             |
| 0            | 1     | 1     | End bit          |

- Response: a response is a token that is sent from an addressed card (or synchronously from all connected cards for MMC V3.31 or previous), to the host as an answer to a previously received command. Responses are transferred serially on the CMD line.

The SDMMC supports two response types. Both use CRC error checking:

- 48 bit short response
- 136 bit long response

**Note:** *If the response does not contain a CRC (CMD1 response), the device driver must ignore the CRC failed status.*

Table 282. Short response format

| Bit position | Width | Value | Description      |
|--------------|-------|-------|------------------|
| 47           | 1     | 0     | Start bit        |
| 46           | 1     | 0     | Transmission bit |
| [45:40]      | 6     | -     | Command index    |
| [39:8]       | 32    | -     | Argument         |
| [7:1]        | 7     | -     | CRC7(or 1111111) |
| 0            | 1     | 1     | End bit          |

Table 283. Long response format

| Bit position | Width | Value  | Description                          |
|--------------|-------|--------|--------------------------------------|
| 135          | 1     | 0      | Start bit                            |
| 134          | 1     | 0      | Transmission bit                     |
| [133:128]    | 6     | 111111 | Reserved                             |
| [127:1]      | 127   | -      | CID or CSD (including internal CRC7) |
| 0            | 1     | 1      | End bit                              |

The command register contains the command index (six bits sent to a card) and the command type. These determine whether the command requires a response, and whether the response is 48 or 136 bits long (see [Section 45.8.4 on page 1592](#)). The command path implements the status flags shown in [Table 284](#):

Table 284. Command path status flags

| Flag     | Description                                               |
|----------|-----------------------------------------------------------|
| CMDREND  | Set if response CRC is OK.                                |
| CCRCFAIL | Set if response CRC fails.                                |
| CMDSENT  | Set when command (that does not require response) is sent |
| CTIMEOUT | Response timeout.                                         |
| CMDACT   | Command transfer in progress.                             |

The CRC generator calculates the CRC checksum for all bits before the CRC code. This includes the start bit, transmitter bit, command index, and command argument (or card status). The CRC checksum is calculated for the first 120 bits of CID or CSD for the long response format. Note that the start bit, transmitter bit and the six reserved bits are not used in the CRC calculation.

The CRC checksum is a 7-bit value:

$$\text{CRC}[6:0] = \text{Remainder} [(M(x) * x^7) / G(x)]$$

$$G(x) = x^7 + x^3 + 1$$

$$M(x) = (\text{start bit}) * x^{39} + \dots + (\text{last bit before CRC}) * x^0, \text{ or}$$

$$M(x) = (\text{start bit}) * x^{119} + \dots + (\text{last bit before CRC}) * x^0$$

## Data path

The data path subunit transfers data to and from cards. [Figure 513](#) shows a block diagram of the data path.

**Figure 513. Data path**

The card databus width can be programmed using the clock control register. If the 4-bit wide bus mode is enabled, data is transferred at four bits per clock cycle over all four data signals (SDMMC\_D[3:0]). If the 8-bit wide bus mode is enabled, data is transferred at eight bits per clock cycle over all eight data signals (SDMMC\_D[7:0]). If the wide bus mode is not enabled, only one bit per clock cycle is transferred over SDMMC\_D0.

Depending on the transfer direction (send or receive), the data path state machine (DPSM) moves to the Wait\_S or Wait\_R state when it is enabled:

- Send: the DPSM moves to the Wait\_S state. If there is data in the transmit FIFO, the DPSM moves to the Send state, and the data path subunit starts sending data to a card.
- Receive: the DPSM moves to the Wait\_R state and waits for a start bit. When it receives a start bit, the DPSM moves to the Receive state, and the data path subunit starts receiving data from a card.

### Data path state machine (DPSM)

The DPSM operates at SDMMC\_CK frequency. Data on the card bus signals is synchronous to the rising edge of SDMMC\_CK. The DPSM has six states, as shown in [Figure 514: Data path state machine \(DPSM\)](#).

Figure 514. Data path state machine (DPSM)

- **Idle:** the data path is inactive, and the SDMMC\_D[7:0] outputs are in Hi-Z. When the data control register is written and the enable bit is set, the DPSM loads the data counter with a new value and, depending on the data direction bit, moves to either the Wait\_S or the Wait\_R state.
- **Wait\_R:** if the data counter equals zero, the DPSM moves to the Idle state when the receive FIFO is empty. If the data counter is not zero, the DPSM waits for a start bit on SDMMC\_D. The DPSM moves to the Receive state if it receives a start bit before a timeout, and loads the data block counter. If it reaches a timeout before it detects a start bit, it moves to the Idle state and sets the timeout status flag.
- **Receive:** serial data received from a card is packed in bytes and written to the data FIFO. Depending on the transfer mode bit in the data control register, the data transfer mode can be either block or stream:
  - In block mode, when the data block counter reaches zero, the DPSM waits until it receives the CRC code. If the received code matches the internally generated CRC code, the DPSM moves to the Wait\_R state. If not, the CRC fail status flag is set and the DPSM moves to the Idle state.
  - In stream mode, the DPSM receives data while the data counter is not zero. When the counter is zero, the remaining data in the shift register is written to the data FIFO, and the DPSM moves to the Wait\_R state.

If a FIFO overrun error occurs, the DPSM sets the FIFO error flag and moves to the Idle state:

- **Wait\_S:** the DPSM moves to the Idle state if the data counter is zero. If not, it waits until the data FIFO empty flag is deasserted, and moves to the Send state.

**Note:** *The DPSM remains in the Wait\_S state for at least two clock periods to meet the  $N_{WR}$  timing requirements, where  $N_{WR}$  is the number of clock cycles between the reception of the card response and the start of the data transfer from the host.*

- **Send:** the DPSM starts sending data to a card. Depending on the transfer mode bit in the data control register, the data transfer mode can be either block or stream:
  - In block mode, when the data block counter reaches zero, the DPSM sends an internally generated CRC code and end bit, and moves to the Busy state.
  - In stream mode, the DPSM sends data to a card while the enable bit is high and the data counter is not zero. It then moves to the Idle state.

If a FIFO underrun error occurs, the DPSM sets the FIFO error flag and moves to the Idle state.

- **Busy:** the DPSM waits for the CRC status flag:
  - If it does not receive a positive CRC status, it moves to the Idle state and sets the CRC fail status flag.
  - If it receives a positive CRC status, it moves to the Wait\_S state if SDMMC\_D0 is not low (the card is not busy).

If a timeout occurs while the DPSM is in the Busy state, it sets the data timeout flag and moves to the Idle state.

The data timer is enabled when the DPSM is in the Wait\_R or Busy state, and generates the data timeout error:

- When transmitting data, the timeout occurs if the DPSM stays in the Busy state for longer than the programmed timeout period
- When receiving data, the timeout occurs if the end of the data is not true, and if the DPSM stays in the Wait\_R state for longer than the programmed timeout period.
- **Data:** data can be transferred from the card to the host or vice versa. Data is transferred via the data lines. They are stored in a FIFO of 32 words, each word is 32 bits wide.

**Table 285. Data token format**

| Description | Start bit | Data | CRC16 | End bit |
|-------------|-----------|------|-------|---------|
| Block Data  | 0         | -    | yes   | 1       |
| Stream Data | 0         | -    | no    | 1       |

## DPSM Flags

The status of the data path subunit transfer is reported by several status flags

**Table 286. DPSM flags**

| Flag     | Description                                                                                                                                                                                                                                    |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DBCKEND  | Set to high when data block send/receive CRC check is passed.<br>In SDIO multibyte transfer mode this flag is set at the end of the transfer (a multibyte transfer is considered as a single block transfer by the host).                      |
| DATAEND  | Set to high when SDMMC_DCOUNT register decrements and reaches 0.<br>DATAEND indicates the end of a transfer on SDMMC data line.                                                                                                                |
| DTIMEOUT | Set to high when data timeout period is reached.<br>When data timer reaches zero while DPSM is in Wait_R or Busy state, timeout is set. DTIMEOUT can be set after DATAEND if DPSM remains in busy state for longer than the programmed period. |
| DCRCFAIL | Set to high when data block send/receive CRC check fails.                                                                                                                                                                                      |

## Data FIFO

The data FIFO (first-in-first-out) subunit is a data buffer with a transmit and receive unit.

The FIFO contains a 32-bit wide, 32-word deep data buffer, and transmit and receive logic. Because the data FIFO operates in the APB2 clock domain (PCLK2), all signals from the subunits in the SDMMC clock domain (SDMMCCLK) are resynchronized.

Depending on the TXACT and RXACT flags, the FIFO can be disabled, transmit enabled, or receive enabled. TXACT and RXACT are driven by the data path subunit and are mutually exclusive:

- The transmit FIFO refers to the transmit logic and data buffer when TXACT is asserted
- The receive FIFO refers to the receive logic and data buffer when RXACT is asserted
- Transmit FIFO:
 

Data can be written to the transmit FIFO through the APB2 interface when the SDMMC is enabled for transmission.

The transmit FIFO is accessible via 32 sequential addresses. The transmit FIFO contains a data output register that holds the data word pointed to by the read pointer. When the data path subunit has loaded its shift register, it increments the read pointer and drives new data out.

If the transmit FIFO is disabled, all status flags are deasserted. The data path subunit asserts TXACT when it transmits data.

Table 287. Transmit FIFO status flags

| Flag     | Description                                                                                                                                                                                                                                                                                                     |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TXFIFO   | Set to high when all 32 transmit FIFO words contain valid data.                                                                                                                                                                                                                                                 |
| TXFIFOE  | Set to high when the transmit FIFO does not contain valid data.                                                                                                                                                                                                                                                 |
| TXFIFOHE | Set to high when 8 or more transmit FIFO words are empty. This flag can be used as a DMA request.                                                                                                                                                                                                               |
| TXDAVL   | Set to high when the transmit FIFO contains valid data. This flag is the inverse of the TXFIFOE flag.                                                                                                                                                                                                           |
| TXUNDERR | Set to high when an underrun error occurs. This flag is cleared by writing to the SDMMC Clear register.<br><i>Note: In case of TXUNDERR, and DMA is used to fill SDMMC FIFO, user software should disable DMA stream, and then write DMAEN bit in SDMMC_DCTRL with '0' (to disable DMA request generation).</i> |

- Receive FIFO

When the data path subunit receives a word of data, it drives the data on the write databus. The write pointer is incremented after the write operation completes. On the read side, the contents of the FIFO word pointed to by the current value of the read pointer is driven onto the read databus. If the receive FIFO is disabled, all status flags are deasserted, and the read and write pointers are reset. The data path subunit asserts RXACT when it receives data. [Table 288](#) lists the receive FIFO status flags. The receive FIFO is accessible via 32 sequential addresses.

Table 288. Receive FIFO status flags

| Flag     | Description                                                                                                                                                                                                                                                                                                   |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RXFIFO   | Set to high when all 32 receive FIFO words contain valid data                                                                                                                                                                                                                                                 |
| RXFIFOE  | Set to high when the receive FIFO does not contain valid data.                                                                                                                                                                                                                                                |
| RXFIFOHF | Set to high when 8 or more receive FIFO words contain valid data. This flag can be used as a DMA request.                                                                                                                                                                                                     |
| RXDAVL   | Set to high when the receive FIFO is not empty. This flag is the inverse of the RXFIFOE flag.                                                                                                                                                                                                                 |
| RXOVERR  | Set to high when an overrun error occurs. This flag is cleared by writing to the SDMMC Clear register.<br><i>Note: In case of RXOVERR, and DMA is used to read SDMMC FIFO, user software should disable DMA stream, and then write DMAEN bit in SDMMC_DCTRL with '0' (to disable DMA request generation).</i> |

### 45.3.2 SDMMC APB2 interface

The APB2 interface generates the interrupt and DMA requests, and accesses the SDMMC adapter registers and the data FIFO. It consists of a data path, register decoder, and interrupt/DMA logic.

#### SDMMC interrupts

The interrupt logic generates an interrupt request signal that is asserted when at least one of the selected status flags is high. A mask register is provided to allow selection of the conditions that will generate an interrupt. A status flag generates the interrupt request if a corresponding mask flag is set.

#### SDMMC/DMA interface

SDMMC APB interface controls all subunit to perform transfers between the host and card

#### Example of read procedure using DMA

Send CMD17 (READ\_BLOCK) as follows:

- a) Program the SDMMC data length register (SDMMC data timer register should be already programmed before the card identification process)
- b) Program DMA channel (refer to [DMA configuration for SDMMC controller](#))
- c) Program the SDMMC data control register: DTEN with '1' (SDMMC card host enabled to send data); DTDIR with '1' (from card to controller); DTMODE with '0' (block data transfer); DMAEN with '1' (DMA enabled); DBLOCKSIZE with 0x9 (512 bytes). Other fields are don't care.
- d) Program the SDMMC argument register with the address location of the card from where data is to be transferred
- e) Program the SDMMC command register: CmdIndex with 17(READ\_BLOCK); WaitResp with '1' (SDMMC card host waits for a response); CPSMEN with '1' (SDMMC card host enabled to send a command). Other fields are at their reset value.
- f) Wait for SDMMC\_STA[6] = CMDREND interrupt, (CMDREND is set if there is no error on command path).
- g) Wait for SDMMC\_STA[10] = DBCKEND, (DBCKEND is set in case of no errors until the CRC check is passed)
- h) Wait until the FIFO is empty, when FIFO is empty the SDMMC\_STA[5] = RXOVERR value has to be checked to guarantee that read succeeded

*Note:* When FIFO overrun error occurs with last 1-4 bytes, it may happen that RXOVERR flag is set 2 APB clock cycles after DATAEND flag is set. To guarantee success of read operation RXOVERR must be checked after FIFO is empty.

### Example of write procedure using DMA

Send CMD24 (WRITE\_BLOCK) as follows:

- a) Program the SDMMC data length register (SDMMC data timer register should be already programmed before the card identification process)
- b) Program DMA channel (refer to [DMA configuration for SDMMC controller](#))
- c) Program the SDMMC argument register with the address location of the card from where data is to be transferred
- d) Program the SDMMC command register: CmdIndex with 24(WRITE\_BLOCK); WaitResp with '1' (SDMMC card host waits for a response); CPSMEN with '1' (SDMMC card host enabled to send a command). Other fields are at their reset value.
- e) Wait for SDMMC\_STA[6] = CMDREND interrupt, then Program the SDMMC data control register: DTEN with '1' (SDMMC card host enabled to send data); DTDIR with '0' (from controller to card); DTMODE with '0' (block data transfer); DMAEN with '1' (DMA enabled); DBLOCKSIZE with 0x9 (512 bytes). Other fields are don't care.
- f) Wait for SDMMC\_STA[10] = DBCKEND, (DBCKEND is set in case of no errors)

### DMA configuration for SDMMC controller

- a) Enable DMA2 controller and clear any pending interrupts
- b) Program the DMA2\_Channel4 (or DMA2\_Channel5) source address register with the memory location base address and DMA2\_Channel4 (or DMA2\_Channel5) destination address register with the SDMMC\_FIFO register address
- c) Program DMA2\_Channel4 (or DMA2\_Channel5) control register (memory increment, not peripheral increment, peripheral and source width is word size)
- d) Enable DMA2\_Channel4 (or DMA2\_Channel5)

## 45.4 Card functional description

### 45.4.1 Card identification mode

While in card identification mode the host resets all cards, validates the operation voltage range, identifies cards and sets a relative card address (RCA) for each card on the bus. All data communications in the card identification mode use the command line (CMD) only.

### 45.4.2 Card reset

The GO\_IDLE\_STATE command (CMD0) is the software reset command and it puts the MultiMediaCard and SD memory in the Idle state. The IO\_RW\_DIRECT command (CMD52) resets the SD I/O card. After power-up or CMD0, all cards output bus drivers are in the high-impedance state and the cards are initialized with a default relative card address (RCA=0x0001) and with a default driver stage register setting (lowest speed, highest driving current capability).

### 45.4.3 Operating voltage range validation

All cards can communicate with the SDMMC card host using any operating voltage within the specification range. The supported minimum and maximum  $V_{DD}$  values are defined in the operation conditions register (OCR) on the card.

Cards that store the card identification number (CID) and card specific data (CSD) in the payload memory are able to communicate this information only under data-transfer  $V_{DD}$  conditions. When the SDMMC card host module and the card have incompatible  $V_{DD}$  ranges, the card is not able to complete the identification cycle and cannot send CSD data. For this purpose, the special commands, SEND\_OP\_COND (CMD1), SD\_APP\_OP\_COND (ACMD41 for SD Memory), and IO\_SEND\_OP\_COND (CMD5 for SD I/O), are designed to provide a mechanism to identify and reject cards that do not match the  $V_{DD}$  range desired by the SDMMC card host. The SDMMC card host sends the required  $V_{DD}$  voltage window as the operand of these commands. Cards that cannot perform data transfer in the specified range disconnect from the bus and go to the inactive state.

By using these commands without including the voltage range as the operand, the SDMMC card host can query each card and determine the common voltage range before placing out-of-range cards in the inactive state. This query is used when the SDMMC card host is able to select a common voltage range or when the user requires notification that cards are not usable.

### 45.4.4 Card identification process

The card identification process differs for MultiMediaCards and SD cards. For MultiMediaCard cards, the identification process starts at clock rate  $F_{od}$ . The SDMMC\_CMD line output drivers are open-drain and allow parallel card operation during this process. The registration process is accomplished as follows:

1. The bus is activated.
2. The SDMMC card host broadcasts SEND\_OP\_COND (CMD1) to receive operation conditions.
3. The response is the wired AND operation of the operation condition registers from all cards.
4. Incompatible cards are placed in the inactive state.
5. The SDMMC card host broadcasts ALL\_SEND\_CID (CMD2) to all active cards.
6. The active cards simultaneously send their CID numbers serially. Cards with outgoing CID bits that do not match the bits on the command line stop transmitting and must wait for the next identification cycle. One card successfully transmits a full CID to the SDMMC card host and enters the Identification state.
7. The SDMMC card host issues SET\_RELATIVE\_ADDR (CMD3) to that card. This new address is called the relative card address (RCA); it is shorter than the CID and addresses the card. The assigned card changes to the Standby state, it does not react to further identification cycles, and its output switches from open-drain to push-pull.
8. The SDMMC card host repeats steps 5 through 7 until it receives a timeout condition.

For the SD card, the identification process starts at clock rate  $F_{od}$ , and the SDMMC\_CMD line output drives are push-pull drivers instead of open-drain. The registration process is accomplished as follows:

1. The bus is activated.
2. The SDMMC card host broadcasts SD\_APP\_OP\_COND (ACMD41).
3. The cards respond with the contents of their operation condition registers.
4. The incompatible cards are placed in the inactive state.
5. The SDMMC card host broadcasts ALL\_SEND\_CID (CMD2) to all active cards.
6. The cards send back their unique card identification numbers (CIDs) and enter the Identification state.
7. The SDMMC card host issues SET\_RELATIVE\_ADDR (CMD3) to an active card with an address. This new address is called the relative card address (RCA); it is shorter than the CID and addresses the card. The assigned card changes to the Standby state. The SDMMC card host can reissue this command to change the RCA. The RCA of the card is the last assigned value.
8. The SDMMC card host repeats steps 5 through 7 with all active cards.

For the SD I/O card, the registration process is accomplished as follows:

1. The bus is activated.
2. The SDMMC card host sends IO\_SEND\_OP\_COND (CMD5).
3. The cards respond with the contents of their operation condition registers.
4. The incompatible cards are set to the inactive state.
5. The SDMMC card host issues SET\_RELATIVE\_ADDR (CMD3) to an active card with an address. This new address is called the relative card address (RCA); it is shorter than the CID and addresses the card. The assigned card changes to the Standby state. The SDMMC card host can reissue this command to change the RCA. The RCA of the card is the last assigned value.

#### 45.4.5 Block write

During block write (CMD24 - 27) one or more blocks of data are transferred from the host to the card with a CRC appended to the end of each block by the host. A card supporting block write is always able to accept a block of data defined by WRITE\_BL\_LEN. If the CRC fails, the card indicates the failure on the SDMMC\_D line and the transferred data are discarded and not written, and all further transmitted blocks (in multiple block write mode) are ignored.

If the host uses partial blocks whose accumulated length is not block aligned and, block misalignment is not allowed (CSD parameter WRITE\_BLK\_MISALIGN is not set), the card will detect the block misalignment error before the beginning of the first misaligned block. (ADDRESS\_ERROR error bit is set in the status register). The write operation will also be aborted if the host tries to write over a write-protected area. In this case, however, the card will set the WP\_VIOLATION bit.

Programming of the CID and CSD registers does not require a previous block length setting. The transferred data is also CRC protected. If a part of the CSD or CID register is stored in ROM, then this unchangeable part must match the corresponding part of the receive buffer. If this match fails, then the card reports an error and does not change any register contents. Some cards may require long and unpredictable times to write a block of data. After receiving a block of data and completing the CRC check, the card begins writing and holds the SDMMC\_D line low if its write buffer is full and unable to accept new data from a new WRITE\_BLOCK command. The host may poll the status of the card with a SEND\_STATUS command (CMD13) at any time, and the card will respond with its status. The READY\_FOR\_DATA status bit indicates whether the card can accept new data or whether the write process is still in progress. The host may deselect the card by issuing CMD7 (to

select a different card), which will place the card in the Disconnect state and release the SDMMC\_D line(s) without interrupting the write operation. When reselecting the card, it will reactivate busy indication by pulling SDMMC\_D to low if programming is still in progress and the write buffer is unavailable.

#### 45.4.6 Block read

In Block read mode the basic unit of data transfer is a block whose maximum size is defined in the CSD (READ\_BL\_LEN). If READ\_BL\_PARTIAL is set, smaller blocks whose start and end addresses are entirely contained within one physical block (as defined by READ\_BL\_LEN) may also be transmitted. A CRC is appended to the end of each block, ensuring data transfer integrity. CMD17 (READ\_SINGLE\_BLOCK) initiates a block read and after completing the transfer, the card returns to the Transfer state.

CMD18 (READ\_MULTIPLE\_BLOCK) starts a transfer of several consecutive blocks.

The host can abort reading at any time, within a multiple block operation, regardless of its type. Transaction abort is done by sending the stop transmission command.

If the card detects an error (for example, out of range, address misalignment or internal error) during a multiple block read operation (both types) it stops the data transmission and remains in the data state. The host must then abort the operation by sending the stop transmission command. The read error is reported in the response to the stop transmission command.

If the host sends a stop transmission command after the card transmits the last block of a multiple block operation with a predefined number of blocks, it is responded to as an illegal command, since the card is no longer in the data state. If the host uses partial blocks whose accumulated length is not block-aligned and block misalignment is not allowed, the card detects a block misalignment error condition at the beginning of the first misaligned block (ADDRESS\_ERROR error bit is set in the status register).

#### 45.4.7 Stream access, stream write and stream read (MultiMediaCard only)

In stream mode, data is transferred in bytes and no CRC is appended at the end of each block.

##### Stream write (MultiMediaCard only)

WRITE\_DAT\_UNTIL\_STOP (CMD20) starts the data transfer from the SDMMC card host to the card, beginning at the specified address and continuing until the SDMMC card host issues a stop command. When partial blocks are allowed (CSD parameter WRITE\_BL\_PARTIAL is set), the data stream can start and stop at any address within the card address space, otherwise it can only start and stop at block boundaries. Because the amount of data to be transferred is not determined in advance, a CRC cannot be used. When the end of the memory range is reached while sending data and no stop command is sent by the SDMMC card host, any additional transferred data are discarded.

The maximum clock frequency for a stream write operation is given by the following equation fields of the card-specific data register:

$$\text{Maximumspeed} = \text{MIN}(\text{TRANSPEED}, \frac{(8 \times 2^{\text{writeblen}})(-\text{NSAC})}{\text{TAAC} \times \text{R2WFACTOR}})$$

- Maximumspeed = maximum write frequency
- TRANSPEED = maximum data transfer rate
- writeblen = maximum write data block length
- NSAC = data read access time 2 in CLK cycles
- TAAC = data read access time 1
- R2WFACTOR = write speed factor

If the host attempts to use a higher frequency, the card may not be able to process the data and stop programming, set the OVERRUN error bit in the status register, and while ignoring all further data transfer, wait (in the receive data state) for a stop command. The write operation is also aborted if the host tries to write over a write-protected area. In this case, however, the card sets the WP\_VIOLATION bit.

### Stream read (MultiMediaCard only)

READ\_DAT\_UNTIL\_STOP (CMD11) controls a stream-oriented data transfer.

This command instructs the card to send its data, starting at a specified address, until the SDMMC card host sends STOP\_TRANSMISSION (CMD12). The stop command has an execution delay due to the serial command transmission and the data transfer stops after the end bit of the stop command. When the end of the memory range is reached while sending data and no stop command is sent by the SDMMC card host, any subsequent data sent are considered undefined.

The maximum clock frequency for a stream read operation is given by the following equation and uses fields of the card specific data register.

$$\text{Maximumspeed} = \text{MIN}(\text{TRANSPEED}, \frac{(8 \times 2^{\text{readblen}})(-\text{NSAC})}{\text{TAAC} \times \text{R2WFACTOR}})$$

- Maximumspeed = maximum read frequency
- TRANSPEED = maximum data transfer rate
- readblen = maximum read data block length
- writeblen = maximum write data block length
- NSAC = data read access time 2 in CLK cycles
- TAAC = data read access time 1
- R2WFACTOR = write speed factor

If the host attempts to use a higher frequency, the card is not able to sustain data transfer. If this happens, the card sets the UNDERRUN error bit in the status register, aborts the transmission and waits in the data state for a stop command.

#### 45.4.8 Erase: group erase and sector erase

The erasable unit of the MultiMediaCard is the erase group. The erase group is measured in write blocks, which are the basic writable units of the card. The size of the erase group is a card-specific parameter and defined in the CSD.

The host can erase a contiguous range of Erase Groups. Starting the erase process is a three-step sequence.

First the host defines the start address of the range using the ERASE\_GROUP\_START (CMD35) command, next it defines the last address of the range using the ERASE\_GROUP\_END (CMD36) command and, finally, it starts the erase process by issuing the ERASE (CMD38) command. The address field in the erase commands is an Erase Group address in byte units. The card ignores all LSBs below the Erase Group size, effectively rounding the address down to the Erase Group boundary.

If an erase command is received out of sequence, the card sets the ERASE\_SEQ\_ERROR bit in the status register and resets the whole sequence.

If an out-of-sequence (neither of the erase commands, except SEND\_STATUS) command received, the card sets the ERASE\_RESET status bit in the status register, resets the erase sequence and executes the last command.

If the erase range includes write protected blocks, they are left intact and only nonprotected blocks are erased. The WP\_ERASE\_SKIP status bit in the status register is set.

The card indicates that an erase is in progress by holding SDMMC\_D low. The actual erase time may be quite long, and the host may issue CMD7 to deselect the card.

#### 45.4.9 Wide bus selection or deselection

Wide bus (4-bit bus width) operation mode is selected or deselected using SET\_BUS\_WIDTH (ACMD6). The default bus width after power-up or GO\_IDLE\_STATE (CMD0) is 1 bit. SET\_BUS\_WIDTH (ACMD6) is only valid in a transfer state, which means that the bus width can be changed only after a card is selected by SELECT/DESELECT\_CARD (CMD7).

#### 45.4.10 Protection management

Three write protection methods for the cards are supported in the SDMMC card host module:

1. internal card write protection (card responsibility)
2. mechanical write protection switch (SDMMC card host module responsibility only)
3. password-protected card lock operation

##### Internal card write protection

Card data can be protected against write and erase. By setting the permanent or temporary write-protect bits in the CSD, the entire card can be permanently write-protected by the manufacturer or content provider. For cards that support write protection of groups of sectors by setting the WP\_GRP\_ENABLE bit in the CSD, portions of the data can be protected, and the write protection can be changed by the application. The write protection is in units of WP\_GRP\_SIZE sectors as specified in the CSD. The SET\_WRITE\_PROT and CLR\_WRITE\_PROT commands control the protection of the addressed group. The SEND\_WRITE\_PROT command is similar to a single block read command. The card sends

a data block containing 32 write protection bits (representing 32 write protect groups starting at the specified address) followed by 16 CRC bits. The address field in the write protect commands is a group address in byte units.

The card ignores all LSBs below the group size.

### Mechanical write protect switch

A mechanical sliding tab on the side of the card allows the user to set or clear the write protection on a card. When the sliding tab is positioned with the window open, the card is write-protected, and when the window is closed, the card contents can be changed. A matched switch on the socket side indicates to the SDMMC card host module that the card is write-protected. The SDMMC card host module is responsible for protecting the card. The position of the write protect switch is unknown to the internal circuitry of the card.

### Password protect

The password protection feature enables the SDMMC card host module to lock and unlock a card with a password. The password is stored in the 128-bit PWD register and its size is set in the 8-bit PWD\_LEN register. These registers are nonvolatile so that a power cycle does not erase them. Locked cards respond to and execute certain commands. This means that the SDMMC card host module is allowed to reset, initialize, select, and query for status, however it is not allowed to access data on the card. When the password is set (as indicated by a nonzero value of PWD\_LEN), the card is locked automatically after power-up. As with the CSD and CID register write commands, the lock/unlock commands are available in the transfer state only. In this state, the command does not include an address argument and the card must be selected before using it. The card lock/unlock commands have the structure and bus transaction types of a regular single-block write command. The transferred data block includes all of the required information for the command (the password setting mode, the PWD itself, and card lock/unlock). The command data block size is defined by the SDMMC card host module before it sends the card lock/unlock command, and has the structure shown in [Table 302](#).

The bit settings are as follows:

- ERASE: setting it forces an erase operation. All other bits must be zero, and only the command byte is sent
- LOCK\_UNLOCK: setting it locks the card. LOCK\_UNLOCK can be set simultaneously with SET\_PWD, however not with CLR\_PWD
- CLR\_PWD: setting it clears the password data
- SET\_PWD: setting it saves the password data to memory
- PWD\_LEN: it defines the length of the password in bytes
- PWD: the password (new or currently used, depending on the command)

The following sections list the command sequences to set/reset a password, lock/unlock the card, and force an erase.

### Setting the password

1. Select a card (SELECT/DESELECT\_CARD, CMD7), if none is already selected.
2. Define the block length (SET\_BLOCKLEN, CMD16) to send, given by the 8-bit card lock/unlock mode, the 8-bit PWD\_LEN, and the number of bytes of the new password.

When a password replacement is done, the block size must take into account that both the old and the new passwords are sent with the command.

3. Send LOCK/UNLOCK (CMD42) with the appropriate data block size on the data line including the 16-bit CRC. The data block indicates the mode (SET\_PWD = 1), the length (PWD\_LEN), and the password (PWD) itself. When a password replacement is done, the length value (PWD\_LEN) includes the length of both passwords, the old and the new one, and the PWD field includes the old password (currently used) followed by the new password.
4. When the password is matched, the new password and its size are saved into the PWD and PWD\_LEN fields, respectively. When the old password sent does not correspond (in size and/or content) to the expected password, the LOCK\_UNLOCK\_FAILED error bit is set in the card status register, and the password is not changed.

The password length field (PWD\_LEN) indicates whether a password is currently set. When this field is nonzero, there is a password set and the card locks itself after power-up. It is possible to lock the card immediately in the current power session by setting the LOCK\_UNLOCK bit (while setting the password) or sending an additional command for card locking.

### Resetting the password

1. Select a card (SELECT/DESELECT\_CARD, CMD7), if none is already selected.
2. Define the block length (SET\_BLOCKLEN, CMD16) to send, given by the 8-bit card lock/unlock mode, the 8-bit PWD\_LEN, and the number of bytes in the currently used password.
3. Send LOCK/UNLOCK (CMD42) with the appropriate data block size on the data line including the 16-bit CRC. The data block indicates the mode (CLR\_PWD = 1), the length (PWD\_LEN) and the password (PWD) itself. The LOCK\_UNLOCK bit is ignored.
4. When the password is matched, the PWD field is cleared and PWD\_LEN is set to 0. When the password sent does not correspond (in size and/or content) to the expected password, the LOCK\_UNLOCK\_FAILED error bit is set in the card status register, and the password is not changed.

### Locking a card

1. Select a card (SELECT/DESELECT\_CARD, CMD7), if none is already selected.
2. Define the block length (SET\_BLOCKLEN, CMD16) to send, given by the 8-bit card lock/unlock mode (byte 0 in [Table 302](#)), the 8-bit PWD\_LEN, and the number of bytes of the current password.
3. Send LOCK/UNLOCK (CMD42) with the appropriate data block size on the data line including the 16-bit CRC. The data block indicates the mode (LOCK\_UNLOCK = 1), the length (PWD\_LEN), and the password (PWD) itself.
4. When the password is matched, the card is locked and the CARD\_IS\_LOCKED status bit is set in the card status register. When the password sent does not correspond (in size and/or content) to the expected password, the LOCK\_UNLOCK\_FAILED error bit is set in the card status register, and the lock fails.

It is possible to set the password and to lock the card in the same sequence. In this case, the SDMMC card host module performs all the required steps for setting the password (see [Setting the password on page 1569](#)), however it is necessary to set the LOCK\_UNLOCK bit in Step 3 when the new password command is sent.

When the password is previously set (PWD\_LEN is not 0), the card is locked automatically after power on reset. An attempt to lock a locked card or to lock a card that does not have a password fails and the LOCK\_UNLOCK\_FAILED error bit is set in the card status register.

### Unlocking the card

1. Select a card (SELECT/DESELECT\_CARD, CMD7), if none is already selected.
2. Define the block length (SET\_BLOCKLEN, CMD16) to send, given by the 8-bit cardlock/unlock mode (byte 0 in [Table 302](#)), the 8-bit PWD\_LEN, and the number of bytes of the current password.
3. Send LOCK/UNLOCK (CMD42) with the appropriate data block size on the data line including the 16-bit CRC. The data block indicates the mode (LOCK\_UNLOCK = 0), the length (PWD\_LEN), and the password (PWD) itself.
4. When the password is matched, the card is unlocked and the CARD\_IS\_LOCKED status bit is cleared in the card status register. When the password sent is not correct in size and/or content and does not correspond to the expected password, the LOCK\_UNLOCK\_FAILED error bit is set in the card status register, and the card remains locked.

The unlocking function is only valid for the current power session. When the PWD field is not clear, the card is locked automatically on the next power-up.

An attempt to unlock an unlocked card fails and the LOCK\_UNLOCK\_FAILED error bit is set in the card status register.

### Forcing erase

If the user has forgotten the password (PWD content), it is possible to access the card after clearing all the data on the card. This forced erase operation erases all card data and all password data.

1. Select a card (SELECT/DESELECT\_CARD, CMD7), if none is already selected.
2. Set the block length (SET\_BLOCKLEN, CMD16) to 1 byte. Only the 8-bit card lock/unlock byte (byte 0 in [Table 302](#)) is sent.
3. Send LOCK/UNLOCK (CMD42) with the appropriate data byte on the data line including the 16-bit CRC. The data block indicates the mode (ERASE = 1). All other bits must be zero.
4. When the ERASE bit is the only bit set in the data field, all card contents are erased, including the PWD and PWD\_LEN fields, and the card is no longer locked. When any other bits are set, the LOCK\_UNLOCK\_FAILED error bit is set in the card status register and the card retains all of its data, and remains locked.

An attempt to use a force erase on an unlocked card fails and the LOCK\_UNLOCK\_FAILED error bit is set in the card status register.

## 45.4.11 Card status register

The response format R1 contains a 32-bit field named card status. This field is intended to transmit the card status information (which may be stored in a local status register) to the host. If not specified otherwise, the status entries are always related to the previously issued command.

[Table 289](#) defines the different entries of the status. The type and clear condition fields in the table are abbreviated as follows:

Type:

- E: error bit
- S: status bit
- R: detected and set for the actual command response
- X: detected and set during command execution. The SDMMC card host must poll the card by issuing the status command to read these bits.

Clear condition:

- A: according to the card current state
- B: always related to the previous command. Reception of a valid command clears it (with a delay of one command)
- C: clear by read

**Table 289. Card status**

| Bits | Identifier           | Type  | Value                         | Description                                                                                                                                                                                                                                                                                                                                                               | Clear condition |
|------|----------------------|-------|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| 31   | ADDRESS_OUT_OF_RANGE | E R X | '0' = no error<br>'1' = error | The command address argument was out of the allowed range for this card.<br>A multiple block or stream read/write operation is (although started in a valid address) attempting to read or write beyond the card capacity.                                                                                                                                                | C               |
| 30   | ADDRESS_MISALIGN     | -     | '0' = no error<br>'1' = error | The commands address argument (in accordance with the currently set block length) positions the first data block misaligned to the card physical blocks.<br>A multiple block read/write operation (although started with a valid address/block-length combination) is attempting to read or write a data block which is not aligned with the physical blocks of the card. | C               |
| 29   | BLOCK_LEN_ERROR      | -     | '0' = no error<br>'1' = error | Either the argument of a SET_BLOCKLEN command exceeds the maximum value allowed for the card, or the previously defined block length is illegal for the current command (e.g. the host issues a write command, the current block length is smaller than the maximum allowed value for the card and it is not allowed to write partial blocks)                             | C               |

Table 289. Card status (continued)

| Bits | Identifier         | Type | Value                                    | Description                                                                                                                                                                                                                                                                              | Clear condition |

#### 45.4.12 SD status register

The SD status contains status bits that are related to the SD memory card proprietary features and may be used for future application-specific usage. The size of the SD Status is one data block of 512 bits. The contents of this register are transmitted to the SDMMC card host if ACMD13 is sent (CMD55 followed with CMD13). ACMD13 can be sent to a card in transfer state only (card is selected).

[Table 290](#) defines the different entries of the SD status register. The type and clear condition fields in the table are abbreviated as follows:

Type:

- E: error bit
- S: status bit
- R: detected and set for the actual command response
- X: detected and set during command execution. The SDMMC card Host must poll the card by issuing the status command to read these bits

Clear condition:

- A: according to the card current state
- B: always related to the previous command. Reception of a valid command clears it (with a delay of one command)
- C: clear by read

**Table 290. SD status**

| Bits     | Identifier             | Type | Value                                                                                                                                                                                        | Description                                                                                                                                                                                                                                       | Clear condition |

| 311:0   | Reserved for Manufacturer |      |                                                                |             |                 |

### SIZE\_OF\_PROTECTED\_AREA

Setting this field differs between standard- and high-capacity cards. In the case of a standard-capacity card, the capacity of protected area is calculated as follows:

$$\text{Protected area} = \text{SIZE\_OF\_PROTECTED\_AREA} \times \text{MULT} \times \text{BLOCK\_LEN}.$$

SIZE\_OF\_PROTECTED\_AREA is specified by the unit in MULT\*BLOCK\_LEN.

In the case of a high-capacity card, the capacity of protected area is specified in this field:

$$\text{Protected area} = \text{SIZE\_OF\_PROTECTED\_AREA}$$

SIZE\_OF\_PROTECTED\_AREA is specified by the unit in bytes.

### SPEED\_CLASS

This 8-bit field indicates the speed class and the value can be calculated by  $P_W/2$  (where  $P_W$  is the write performance).

Table 291. Speed class code field

| SPEED_CLASS | Value definition |
|-------------|------------------|
| 00h         | Class 0          |
| 01h         | Class 2          |
| 02h         | Class 4          |
| 03h         | Class 6          |
| 04h – FFh   | Reserved         |

**PERFORMANCE\_MOVE**

This 8-bit field indicates Pm (performance move) and the value can be set by 1 [MB/sec] steps. If the card does not move used RUs (recording units), Pm should be considered as infinity. Setting the field to FFh means infinity.

**Table 292. Performance move field**

| <b>PERFORMANCE_MOVE</b> | <b>Value definition</b> |
|-------------------------|-------------------------|
| 00h                     | Not defined             |
| 01h                     | 1 [MB/sec]              |
| 02h                     | 02h 2 [MB/sec]          |

**AU\_SIZE**

This 4-bit field indicates the AU size and the value can be selected in the power of 2 base from 16 KB.

**Table 293. AU\_SIZE field**

| <b>AU_SIZE</b> | <b>Value definition</b> |
|----------------|-------------------------|
| 00h            | Not defined             |
| 01h            | 16 KB                   |
| 02h            | 32 KB                   |
| 03h            | 64 KB                   |
| 04h            | 128 KB                  |
| 05h            | 256 KB                  |
| 06h            | 512 KB                  |
| 07h            | 1 MB                    |
| 08h            | 2 MB                    |
| 09h            | 4 MB                    |
| Ah – Fh        | Reserved                |

The maximum AU size, which depends on the card capacity, is defined in [Table 294](#). The card can be set to any AU size between RU size and maximum AU size.

**Table 294. Maximum AU size**

| <b>Capacity</b> | <b>16 MB-64 MB</b> | <b>128 MB-256 MB</b> | <b>512 MB</b> | <b>1 GB-32 GB</b> |
|-----------------|--------------------|----------------------|---------------|-------------------|
| Maximum AU Size | 512 KB             | 1 MB                 | 2 MB          | 4 MB              |

**ERASE\_SIZE**

This 16-bit field indicates  $N_{ERASE}$ . When  $N_{ERASE}$  numbers of AUs are erased, the timeout value is specified by ERASE\_TIMEOUT (Refer to [ERASE\\_TIMEOUT](#)). The host should determine the proper number of AUs to be erased in one operation so that the host can show the progress of the erase operation. If this field is set to 0, the erase timeout calculation is not supported.

**Table 295. Erase size field**

| ERASE_SIZE | Value definition                            |
|------------|---------------------------------------------|
| 0000h      | Erase timeout calculation is not supported. |
| 0001h      | 1 AU                                        |
| 0002h      | 2 AU                                        |
| 0003h      | 3 AU                                        |
| -----      | -----                                       |
| FFFFh      | 65535 AU                                    |

**ERASE\_TIMEOUT**

This 6-bit field indicates  $T_{ERASE}$  and the value indicates the erase timeout from offset when multiple AUs are being erased as specified by ERASE\_SIZE. The range of ERASE\_TIMEOUT can be defined as up to 63 seconds and the card manufacturer can choose any combination of ERASE\_SIZE and ERASE\_TIMEOUT depending on the implementation. Determining ERASE\_TIMEOUT determines the ERASE\_SIZE.

**Table 296. Erase timeout field**

| ERASE_TIMEOUT | Value definition                            |
|---------------|---------------------------------------------|
| 00            | Erase timeout calculation is not supported. |
| 01            | 1 [sec]                                     |
| 02            | 2 [sec]                                     |
| 03            | 3 [sec]                                     |
| -----         | -----                                       |
| 63            | 63 [sec]                                    |

**ERASE\_OFFSET**

This 2-bit field indicates  $T_{OFFSET}$  and one of four values can be selected. This field is meaningless if the ERASE\_SIZE and ERASE\_TIMEOUT fields are set to 0.

**Table 297. Erase offset field**

| ERASE_OFFSET | Value definition |
|--------------|------------------|
| 0h           | 0 [sec]          |
| 1h           | 1 [sec]          |

Table 297. Erase offset field (continued)

| ERASE_OFFSET | Value definition |
|--------------|------------------|
| 2h           | 2 [sec]          |
| 3h           | 3 [sec]          |

#### 45.4.13 SD I/O mode

##### SD I/O interrupts

To allow the SD I/O card to interrupt the MultiMediaCard/SD module, an interrupt function is available on a pin on the SD interface. Pin 8, used as SDMMC\_D1 when operating in the 4-bit SD mode, signals the cards interrupt to the MultiMediaCard/SD module. The use of the interrupt is optional for each card or function within a card. The SD I/O interrupt is level-sensitive, which means that the interrupt line must be held active (low) until it is either recognized and acted upon by the MultiMediaCard/SD module or deasserted due to the end of the interrupt period. After the MultiMediaCard/SD module has serviced the interrupt, the interrupt status bit is cleared via an I/O write to the appropriate bit in the SD I/O card's internal registers. The interrupt output of all SD I/O cards is active low and the application must provide pull-up resistors externally on all data lines (SDMMC\_D[3:0]). The MultiMediaCard/SD module samples the level of pin 8 (SDMMC\_D/IRQ) into the interrupt detector only during the interrupt period. At all other times, the MultiMediaCard/SD module ignores this value.

The interrupt period is applicable for both memory and I/O operations. The definition of the interrupt period for operations with single blocks is different from the definition for multiple-block data transfers.

##### SD I/O suspend and resume

Within a multifunction SD I/O or a card with both I/O and memory functions, there are multiple devices (I/O and memory) that share access to the MMC/SD bus. To share access to the MMC/SD module among multiple devices, SD I/O and combo cards optionally implement the concept of suspend/resume. When a card supports suspend/resume, the MMC/SD module can temporarily halt a data transfer operation to one function or memory (suspend) to free the bus for a higher-priority transfer to a different function or memory. After this higher-priority transfer is complete, the original transfer is resumed (restarted) where it left off. Support of suspend/resume is optional on a per-card basis. To perform the suspend/resume operation on the MMC/SD bus, the MMC/SD module performs the following steps:

1. Determines the function currently using the SDMMC\_D [3:0] line(s)
2. Requests the lower-priority or slower transaction to suspend
3. Waits for the transaction suspension to complete
4. Begins the higher-priority transaction
5. Waits for the completion of the higher priority transaction
6. Restores the suspended transaction

##### SD I/O ReadWait

The optional ReadWait (RW) operation is defined only for the SD 1-bit and 4-bit modes. The ReadWait operation allows the MMC/SD module to signal a card that it is reading multiple

registers (IO\_RW\_EXTENDED, CMD53) to temporarily stall the data transfer while allowing the MMC/SD module to send commands to any function within the SD I/O device. To determine when a card supports the ReadWait protocol, the MMC/SD module must test capability bits in the internal card registers. The timing for ReadWait is based on the interrupt period.

## 45.4.14 Commands and responses

### Application-specific and general commands

The SDMMC card host module system is designed to provide a standard interface for a variety of applications types. In this environment, there is a need for specific customer/application features. To implement these features, two types of generic commands are defined in the standard: application-specific commands (ACMD) and general commands (GEN\_CMD).

When the card receives the APP\_CMD (CMD55) command, the card expects the next command to be an application-specific command. ACMDs have the same structure as regular MultiMediaCard commands and can have the same CMD number. The card recognizes it as ACMD because it appears after APP\_CMD (CMD55). When the command immediately following the APP\_CMD (CMD55) is not a defined application-specific command, the standard command is used. For example, when the card has a definition for SD\_STATUS (ACMD13), and receives CMD13 immediately following APP\_CMD (CMD55), this is interpreted as SD\_STATUS (ACMD13). However, when the card receives CMD7 immediately following APP\_CMD (CMD55) and the card does not have a definition for ACMD7, this is interpreted as the standard (SELECT/DESELECT\_CARD) CMD7.

To use one of the manufacturer-specific ACMDs the SD card Host must perform the following steps:

1. Send APP\_CMD (CMD55)  
The card responds to the MultiMediaCard/SD module, indicating that the APP\_CMD bit is set and an ACMD is now expected.
2. Send the required ACMD  
The card responds to the MultiMediaCard/SD module, indicating that the APP\_CMD bit is set and that the accepted command is interpreted as an ACMD. When a nonACMD is sent, it is handled by the card as a normal MultiMediaCard command and the APP\_CMD bit in the card status register stays clear.

When an invalid command is sent (neither ACMD nor CMD) it is handled as a standard MultiMediaCard illegal command error.

The bus transaction for a GEN\_CMD is the same as the single-block read or write commands (WRITE\_BLOCK, CMD24 or READ\_SINGLE\_BLOCK, CMD17). In this case, the argument denotes the direction of the data transfer rather than the address, and the data block has vendor-specific format and meaning.

The card must be selected (in transfer state) before sending GEN\_CMD (CMD56). The data block size is defined by SET\_BLOCKLEN (CMD16). The response to GEN\_CMD (CMD56) is in R1b format.

## Command types

Both application-specific and general commands are divided into the four following types:

- **broadcast command (BC):** sent to all cards; no responses returned.
- **broadcast command with response (BCR):** sent to all cards; responses received from all cards simultaneously.
- **addressed (point-to-point) command (AC):** sent to the card that is selected; does not include a data transfer on the SDMMC\_D line(s).
- **addressed (point-to-point) data transfer command (ADTC):** sent to the card that is selected; includes a data transfer on the SDMMC\_D line(s).

## Command formats

See [Table 281 on page 1555](#) for command formats.

## Commands for the MultiMediaCard/SD module

**Table 298. Block-oriented write commands**

| CMD index | Type | Argument                                    | Response format | Abbreviation                | Description                                                                                                                                                                                                                            |
|-----------|------|---------------------------------------------|-----------------|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CMD23     | ac   | [31:16] set to 0<br>[15:0] number of blocks | R1              | <b>SET_BLOCK_COUNT</b>      | Defines the number of blocks which are going to be transferred in the multiple-block read or write command that follows.                                                                                                               |
| CMD24     | adtc | [31:0] data address                         | R1              | <b>WRITE_BLOCK</b>          | Writes a block of the size selected by the SET_BLOCKLEN command.                                                                                                                                                                       |
| CMD25     | adtc | [31:0] data address                         | R1              | <b>WRITE_MULTIPLE_BLOCK</b> | Continuously writes blocks of data until a STOP_TRANSMISSION follows or the requested number of blocks has been received.                                                                                                              |
| CMD26     | adtc | [31:0] stuff bits                           | R1              | <b>PROGRAM_CID</b>          | Programming of the card identification register. This command must be issued only once per card. The card contains hardware to prevent this operation after the first programming. Normally this command is reserved for manufacturer. |
| CMD27     | adtc | [31:0] stuff bits                           | R1              | <b>PROGRAM_CSD</b>          | Programming of the programmable bits of the CSD.                                                                                                                                                                                       |

Table 299. Block-oriented write protection commands

| CMD index | Type     | Argument                          | Response format | Abbreviation           | Description                                                                                                                                                                                         |
|-----------|----------|-----------------------------------|-----------------|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CMD28     | ac       | [31:0] data address               | R1b             | <b>SET_WRITE_PROT</b>  | If the card has write protection features, this command sets the write protection bit of the addressed group. The properties of write protection are coded in the card-specific data (WP_GRP_SIZE). |
| CMD29     | ac       | [31:0] data address               | R1b             | <b>CLR_WRITE_PROT</b>  | If the card provides write protection features, this command clears the write protection bit of the addressed group.                                                                                |
| CMD30     | adtc     | [31:0] write protect data address | R1              | <b>SEND_WRITE_PROT</b> | If the card provides write protection features, this command asks the card to send the status of the write protection bits.                                                                         |
| CMD31     | Reserved |                                   |                 |                        |                                                                                                                                                                                                     |

Table 300. Erase commands

| CMD index             | Type                                                                                                                                  | Argument            | Response format | Abbreviation             | Description                                                                                  |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------|---------------------|-----------------|--------------------------|----------------------------------------------------------------------------------------------|
| CMD32<br>...<br>CMD34 | Reserved. These command indexes cannot be used in order to maintain backward compatibility with older versions of the MultiMediaCard. |                     |                 |                          |                                                                                              |
| CMD35                 | ac                                                                                                                                    | [31:0] data address | R1              | <b>ERASE_GROUP_START</b> | Sets the address of the first erase group within a range to be selected for erase.           |
| CMD36                 | ac                                                                                                                                    | [31:0] data address | R1              | <b>ERASE_GROUP_END</b>   | Sets the address of the last erase group within a continuous range to be selected for erase. |
| CMD37                 | Reserved. This command index cannot be used in order to maintain backward compatibility with older versions of the MultiMediaCards    |                     |                 |                          |                                                                                              |
| CMD38                 | ac                                                                                                                                    | [31:0] stuff bits   | R1              | <b>ERASE</b>             | Erases all previously selected write blocks.                                                 |

Table 301. I/O mode commands

| CMD index | Type | Argument                                                                                     | Response format | Abbreviation   | Description                                                                                                                                                                                                                                                                                                                             |
|-----------|------|----------------------------------------------------------------------------------------------|-----------------|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CMD39     | ac   | [31:16] RCA<br>[15:15] register write flag<br>[14:8] register address<br>[7:0] register data | R4              | <b>FAST_IO</b> | Used to write and read 8-bit (register) data fields. The command addresses a card and a register and provides the data for writing if the write flag is set. The R4 response contains data read from the addressed register. This command accesses application-dependent registers that are not defined in the MultiMediaCard standard. |

Table 301. I/O mode commands (continued)

| CMD index | Type     | Argument          | Response format | Abbreviation        | Description                              |
|-----------|----------|-------------------|-----------------|---------------------|------------------------------------------|
| CMD40     | bcr      | [31:0] stuff bits | R5              | <b>GO_IRQ_STATE</b> | Places the system in the interrupt mode. |
| CMD41     | Reserved |                   |                 |                     |                                          |

Table 302. Lock card

| CMD index             | Type     | Argument          | Response format | Abbreviation       | Description                                                                                                         |
|-----------------------|----------|-------------------|-----------------|--------------------|---------------------------------------------------------------------------------------------------------------------|
| CMD42                 | adtc     | [31:0] stuff bits | R1b             | <b>LOCK_UNLOCK</b> | Sets/resets the password or locks/unlocks the card. The size of the data block is set by the SET_BLOCK_LEN command. |
| CMD43<br>...<br>CMD54 | Reserved |                   |                 |                    |                                                                                                                     |

Table 303. Application-specific commands

| CMD index             | Type                       | Argument                         | Response format | Abbreviation   | Description                                                                                                                                                                                                    |
|-----------------------|----------------------------|----------------------------------|-----------------|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CMD55                 | ac                         | [31:16] RCA<br>[15:0] stuff bits | R1              | <b>APP_CMD</b> | Indicates to the card that the next command bits is an application specific command rather than a standard command                                                                                             |
| CMD56                 | adtc                       | [31:1] stuff bits<br>[0]: RD/WR  | -               | -              | Used either to transfer a data block to the card or to get a data block from the card for general purpose/application-specific commands. The size of the data block shall be set by the SET_BLOCK_LEN command. |
| CMD57<br>...<br>CMD59 | Reserved.                  |                                  |                 |                |                                                                                                                                                                                                                |
| CMD60<br>...<br>CMD63 | Reserved for manufacturer. |                                  |                 |                |                                                                                                                                                                                                                |

## 45.5 Response formats

All responses are sent via the SDMMC command line SDMMC\_CMD. The response transmission always starts with the left bit of the bit string corresponding to the response code word. The code length depends on the response type.

A response always starts with a start bit (always 0), followed by the bit indicating the direction of transmission (card = 0). A value denoted by x in the tables below indicates a variable entry. All responses, except for the R3 response type, are protected by a CRC. Every command code word is terminated by the end bit (always 1).

There are five types of responses. Their formats are defined as follows:

### 45.5.1 R1 (normal response command)

Code length = 48 bits. The 45:40 bits indicate the index of the command to be responded to, this value being interpreted as a binary-coded number (between 0 and 63). The status of the card is coded in 32 bits.

**Table 304. R1 response**

| Bit position | Width (bits) | Value | Description      |
|--------------|--------------|-------|------------------|
| 47           | 1            | 0     | Start bit        |
| 46           | 1            | 0     | Transmission bit |
| [45:40]      | 6            | X     | Command index    |
| [39:8]       | 32           | X     | Card status      |
| [7:1]        | 7            | X     | CRC7             |
| 0            | 1            | 1     | End bit          |

### 45.5.2 R1b

It is identical to R1 with an optional busy signal transmitted on the data line. The card may become busy after receiving these commands based on its state prior to the command reception.

### 45.5.3 R2 (CID, CSD register)

Code length = 136 bits. The contents of the CID register are sent as a response to the CMD2 and CMD10 commands. The contents of the CSD register are sent as a response to CMD9. Only the bits [127...1] of the CID and CSD are transferred, the reserved bit [0] of these registers is replaced by the end bit of the response. The card indicates that an erase is in progress by holding SDMMC\_D0 low. The actual erase time may be quite long, and the host may issue CMD7 to deselect the card.

**Table 305. R2 response**

| Bit position | Width (bits) | Value    | Description      |
|--------------|--------------|----------|------------------|
| 135          | 1            | 0        | Start bit        |
| 134          | 1            | 0        | Transmission bit |
| [133:128]    | 6            | '111111' | Command index    |
| [127:1]      | 127          | X        | Card status      |
| 0            | 1            | 1        | End bit          |

### 45.5.4 R3 (OCR register)

Code length: 48 bits. The contents of the OCR register are sent as a response to CMD1. The level coding is as follows: restricted voltage windows = low, card busy = low.

**Table 306. R3 response**

| Bit position | Width (bits) | Value     | Description      |
|--------------|--------------|-----------|------------------|
| 47           | 1            | 0         | Start bit        |
| 46           | 1            | 0         | Transmission bit |
| [45:40]      | 6            | '111111'  | Reserved         |
| [39:8]       | 32           | X         | OCR register     |
| [7:1]        | 7            | '1111111' | Reserved         |
| 0            | 1            | 1         | End bit          |

### 45.5.5 R4 (Fast I/O)

Code length: 48 bits. The argument field contains the RCA of the addressed card, the register address to be read out or written to, and its content.

**Table 307. R4 response**

| Bit position          |         | Width (bits) | Value    | Description            |
|-----------------------|---------|--------------|----------|------------------------|
| 47                    |         | 1            | 0        | Start bit              |
| 46                    |         | 1            | 0        | Transmission bit       |
| [45:40]               |         | 6            | ‘100111’ | CMD39                  |
| [39:8] Argument field | [31:16] | 16           | X        | RCA                    |
|                       | [15:8]  | 8            | X        | register address       |
|                       | [7:0]   | 8            | X        | read register contents |
| [7:1]                 |         | 7            | X        | CRC7                   |
| 0                     |         | 1            | 1        | End bit                |

### 45.5.6 R4b

For SD I/O only: an SDIO card receiving the CMD5 will respond with a unique SDIO response R4. The format is:

**Table 308. R4b response**

| Bit position | Width (bits) | Value | Description      |
|--------------|--------------|-------|------------------|
| 47           | 1            | 0     | Start bit        |
| 46           | 1            | 0     | Transmission bit |
| [45:40]      | 6            | X     | Reserved         |

Table 308. R4b response (continued)

| Bit position          |         | Width (bits) | Value | Description             |
|-----------------------|---------|--------------|-------|-------------------------|
| [39:8] Argument field | 39      | 16           | X     | Card is ready           |
|                       | [38:36] | 3            | X     | Number of I/O functions |
|                       | 35      | 1            | X     | Present memory          |
|                       | [34:32] | 3            | X     | Stuff bits              |
|                       | [31:8]  | 24           | X     | I/O ORC                 |
| [7:1]                 |         | 7            | X     | Reserved                |
| 0                     |         | 1            | 1     | End bit                 |

Once an SD I/O card has received a CMD5, the I/O portion of that card is enabled to respond normally to all further commands. This I/O enable of the function within the I/O card will remain set until a reset, power cycle or CMD52 with write to I/O reset is received by the card. Note that an SD memory-only card may respond to a CMD5. The proper response for a memory-only card would be *Present memory* = 1 and *Number of I/O functions* = 0. A memory-only card built to meet the SD Memory Card specification version 1.0 would detect the CMD5 as an illegal command and not respond. The I/O aware host will send CMD5. If the card responds with response R4, the host determines the card's configuration based on the data contained within the R4 response.

#### 45.5.7 R5 (interrupt request)

Only for MultiMediaCard. Code length: 48 bits. If the response is generated by the host, the RCA field in the argument will be 0x0.

Table 309. R5 response

| Bit position          |         | Width (bits) | Value    | Description                                |
|-----------------------|---------|--------------|----------|--------------------------------------------|
| 47                    |         | 1            | 0        | Start bit                                  |
| 46                    |         | 1            | 0        | Transmission bit                           |
| [45:40]               |         | 6            | '101000' | CMD40                                      |
| [39:8] Argument field | [31:16] | 16           | X        | RCA [31:16] of winning card or of the host |
|                       | [15:0]  | 16           | X        | Not defined. May be used for IRQ data      |
| [7:1]                 |         | 7            | X        | CRC7                                       |
| 0                     |         | 1            | 1        | End bit                                    |

#### 45.5.8 R6

Only for SD I/O. The normal response to CMD3 by a memory device. It is shown in [Table 310](#).

Table 310. R6 response

| Bit position          |         | Width (bits) | Value    | Description                                |
|-----------------------|---------|--------------|----------|--------------------------------------------|
| 47                    |         | 1            | 0        | Start bit                                  |
| 46                    |         | 1            | 0        | Transmission bit                           |
| [45:40]               |         | 6            | '101000' | CMD40                                      |
| [39:8] Argument field | [31:16] | 16           | X        | RCA [31:16] of winning card or of the host |
|                       | [15:0]  | 16           | X        | Not defined. May be used for IRQ data      |
| [7:1]                 |         | 7            | X        | CRC7                                       |
| 0                     |         | 1            | 1        | End bit                                    |

The card [23:8] status bits are changed when CMD3 is sent to an I/O-only card. In this case, the 16 bits of response are the SD I/O-only values:

- Bit [15] COM\_CRC\_ERROR
- Bit [14] ILLEGAL\_COMMAND
- Bit [13] ERROR
- Bits [12:0] Reserved

## 45.6 SDIO I/O card-specific operations

The following features are SD I/O-specific operations:

- SDIO read wait operation by SDMMC\_D2 signalling
- SDIO read wait operation by stopping the clock
- SDIO suspend/resume operation (write and read suspend)
- SDIO interrupts

The SDMMC supports these operations only if the SDMMC\_DCTRL[11] bit is set, except for read suspend that does not need specific hardware implementation.

### 45.6.1 SDIO I/O read wait operation by SDMMC\_D2 signalling

It is possible to start the readwait interval before the first block is received: when the data path is enabled (SDMMC\_DCTRL[0] bit set), the SDIO-specific operation is enabled (SDMMC\_DCTRL[11] bit set), read wait starts (SDMMC\_DCTRL[10] = 0 and SDMMC\_DCTRL[8] = 1) and data direction is from card to SDMMC (SDMMC\_DCTRL[1] = 1), the DPSM directly moves from Idle to Readwait. In Readwait the DPSM drives SDMMC\_D2 to 0 after 2 SDMMC\_CK clock cycles. In this state, when you set the RWSTOP bit (SDMMC\_DCTRL[9]), the DPSM remains in Wait for two more SDMMC\_CK clock cycles to drive SDMMC\_D2 to 1 for one clock cycle (in accordance with SDIO specification). The DPSM then starts waiting again until it receives data from the card. The DPSM will not start a readwait interval while receiving a block even if read wait start is set: the readwait interval will start after the CRC is received. The RWSTOP bit has to be cleared to start a new read wait operation. During the readwait interval, the SDMMC can detect SDIO interrupts on SDMMC\_D1.

### 45.6.2 SDIO read wait operation by stopping SDMMC\_CLK

If the SDIO card does not support the previous read wait method, the SDMMC can perform a read wait by stopping SDMMC\_CLK (SDMMC\_DCTRL is set just like in the method presented in [Section 45.6.1](#), but SDMMC\_DCTRL[10] = 1): DSPM stops the clock two SDMMC\_CLK cycles after the end bit of the current received block and starts the clock again after the read wait start bit is set.

As SDMMC\_CLK is stopped, any command can be issued to the card. During a read/wait interval, the SDMMC can detect SDIO interrupts on SDMMC\_D1.

### 45.6.3 SDIO suspend/resume operation

While sending data to the card, the SDMMC can suspend the write operation. the SDMMC\_CMD[11] bit is set and indicates to the CPSM that the current command is a suspend command. The CPSM analyzes the response and when the ACK is received from the card (suspend accepted), it acknowledges the DPSM that goes Idle after receiving the CRC token of the current block.

The hardware does not save the number of the remaining block to be sent to complete the suspended operation (resume).

The write operation can be suspended by software, just by disabling the DPSM (SDMMC\_DCTRL[0] = 0) when the ACK of the suspend command is received from the card. The DPSM enters then the Idle state.

To suspend a read: the DPSM waits in the Wait\_r state as the function to be suspended sends a complete packet just before stopping the data transaction. The application continues reading RxFIFO until the FIFO is empty, and the DPSM goes Idle automatically.

### 45.6.4 SDIO interrupts

SDIO interrupts are detected on the SDMMC\_D1 line once the SDMMC\_DCTRL[11] bit is set.

When SDIO interrupt is detected, SDMMC\_STA[22] (SDIOIT) bit is set. This static bit can be cleared with clear bit SDMMC\_ICR[22] (SDIOITC). An interrupt can be generated when SDIOIT status bit is set. Separated interrupt enable SDMMC\_MASK[22] bit (SDIOITE) is available to enable and disable interrupt request.

When SD card interrupt occurs (SDMMC\_STA[22] bit set), host software follows below steps to handle it.

1. Disable SDIOIT interrupt signaling by clearing SDIOITE bit (SDMMC\_MASK[22] = '0'),
2. Serve card interrupt request, and clear the source of interrupt on the SD card,
3. Clear SDIOIT bit by writing '1' to SDIOITC bit (SDMMC\_ICR[22] = '1'),
4. Enable SDIOIT interrupt signaling by writing '1' to SDIOITE bit (SDMMC\_MASK[22] = '1').

*Steps 2 to 4 can be executed out of the SDIO interrupt service routine.*

## 45.7 HW flow control

The HW flow control functionality is used to avoid FIFO underrun (TX mode) and overrun (RX mode) errors.

The behavior is to stop SDMMC\_CLK and freeze SDMMC state machines. The data transfer is stalled while the FIFO is unable to transmit or receive data. Only state machines clocked by SDMMCCLK are frozen, the APB2 interface is still alive. The FIFO can thus be filled or emptied even if flow control is activated.

To enable HW flow control, the SDMMC\_CLKCR[14] register bit must be set to 1. After reset Flow Control is disabled.

## 45.8 SDMMC registers

The device communicates to the system via 32-bit-wide control registers accessible via APB2.

### 45.8.1 SDMMC power control register (SDMMC\_POWER)

Address offset: 0x00

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |      |      |      |      |      |         |      |

Bits 31:2 Reserved, must be kept at reset value.

[1:0] **PWRCTRL**: Power supply control bits.

These bits are used to define the current functional state of the card clock:

00: Power-off: the clock to card is stopped.

01: Reserved

10: Reserved power-up

11: Power-on: the card is clocked.

**Note:** At least seven PCLK2 clock periods are needed between two write accesses to this register.

**Note:** After a data write, data cannot be written to this register for three SDMMCCLK clock periods plus two PCLK2 clock periods.

### 45.8.2 SDMMC clock control register (SDMMC\_CLKCR)

Address offset: 0x04

Reset value: 0x0000 0000

The SDMMC\_CLKCR register controls the SDMMC\_CLK output clock.

|      |             |             |            |      |            |            |       |        |      |      |      |      |      |      |      |

| Res. | HWFC<br>_EN | NEGE<br>DGE | WID<br>BUS |      | BYPAS<br>S | PWRS<br>AV | CLKEN | CLKDIV |      |      |      |      |      |      |      |
|      | rw          | rw          | rw         | rw   | rw         | rw         | rw    | rw     | rw   | rw   | rw   | rw   | rw   | rw   | rw   |

Bits 31:15 Reserved, must be kept at reset value.

Bit 14 **HWFC\_EN**: HW Flow Control enable

0b: HW Flow Control is disabled

1b: HW Flow Control is enabled

When HW Flow Control is enabled, the meaning of the TXFIFOE and RXFIFOE interrupt signals, see SDMMC Status register definition in [Section 45.8.11](#).

Bit 13 **NEGEDGE**: SDMMC\_CK dephasing selection bit

0b: Command and Data changed on the SDMMCCLK falling edge succeeding the rising edge of SDMMC\_CK. (SDMMC\_CK rising edge occurs on SDMMCCLK rising edge).

1b: Command and Data changed on the SDMMC\_CK falling edge.

When BYPASS is active, the data and the command change on SDMMCCLK falling edge whatever NEGEDGE value.

Bits 12:11 **WIDBUS**: Wide bus mode enable bit

00: Default bus mode: SDMMC\_D0 used

01: 4-wide bus mode: SDMMC\_D[3:0] used

10: 8-wide bus mode: SDMMC\_D[7:0] used

Bit 10 **BYPASS**: Clock divider bypass enable bit

0: Disable bypass: SDMMCCLK is divided according to the CLKDIV value before driving the SDMMC\_CK output signal.

1: Enable bypass: SDMMCCLK directly drives the SDMMC\_CK output signal.

Bit 9 **PWRSAPV**: Power saving configuration bit

For power saving, the SDMMC\_CK clock output can be disabled when the bus is idle by setting PWRSAPV:

0: SDMMC\_CK clock is always enabled

1: SDMMC\_CK is only enabled when the bus is active

Bit 8 **CLKEN**: Clock enable bit

0: SDMMC\_CK is disabled

1: SDMMC\_CK is enabled

Bits 7:0 **CLKDIV**: Clock divide factor

This field defines the divide factor between the input clock (SDMMCCLK) and the output clock (SDMMC\_CK):  $\text{SDMMC\_CK frequency} = \text{SDMMCCLK} / [\text{CLKDIV} + 2]$ .

*Note:* Only even values of CLKDIV are supported (in order to have a duty cycle of 50%).

- Note:**
- 1 While the SD/SDIO card or MultiMediaCard is in identification mode, the SDMMC\_CK frequency must be less than 400 kHz.
  - 2 The clock frequency can be changed to the maximum card bus frequency when relative card addresses are assigned to all cards.
  - 3 After a data write, data cannot be written to this register for three SDMMCCLK clock periods plus two PCLK2 clock periods. SDMMC\_CK can also be stopped during the read wait

*interval for SD I/O cards: in this case the SDMMC\_CLKCR register does not control SDMMC\_CLK.*

### 45.8.3 SDMMC argument register (SDMMC\_ARG)

Address offset: 0x08

Reset value: 0x0000 0000

The SDMMC\_ARG register contains a 32-bit command argument, which is sent to a card as part of a command message.

|               |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|---------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31            | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| CMDARG[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw            | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

| CMDARG[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw            | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:0 **CMDARG**: Command argument

Command argument sent to a card as part of a command message. If a command contains an argument, it must be loaded into this register before writing a command to the command register.

### 45.8.4 SDMMC command register (SDMMC\_CMD)

Address offset: 0x0C

Reset value: 0x0000 0000

The SDMMC\_CMD register contains the command index and command type bits. The command index is sent to a card as part of a command message. The command type bits control the command path state machine (CPSM).

|      |      |      |      |              |         |           |          |          |      |          |      |      |      |      |      |
|------|------|------|------|--------------|---------|-----------|----------|----------|------|----------|------|------|------|------|------|

| Res. | Res. | Res. | Res. | Res.         | Res.    | Res.      | Res.     | Res.     | Res. | Res.     | Res. | Res. | Res. | Res. | Res. |
|      |      |      |      |              |         |           |          |          |      |          |      |      |      |      |      |
| 15   | 14   | 13   | 12   | 11           | 10      | 9         | 8        | 7        | 6    | 5        | 4    | 3    | 2    | 1    | 0    |
| Res. | Res. | Res. | Res. | SDIO Suspend | CPSM EN | WAIT PEND | WAIT INT | WAITRESP |      | CMDINDEX |      |      |      |      |      |
|      |      |      |      | rw           | rw      | rw        | rw       | rw       | rw   | rw       | rw   | rw   | rw   | rw   | rw   |

Bits 31:12 Reserved, must be kept at reset value.

Bit 11 **SDIOSuspend**: SD I/O suspend command

If this bit is set, the command to be sent is a suspend command (to be used only with SDIO card).

Bit 10 **CPSMEN**: Command path state machine (CPSM) Enable bit

If this bit is set, the CPSM is enabled.

Bit 9 **WAITPEND**: CPSM Waits for ends of data transfer (CmdPend internal signal).

If this bit is set, the CPSM waits for the end of data transfer before it starts sending a command. This feature is available only with Stream data transfer mode  
SDMMC\_DCTRL[2] = 1.

Bit 8 **WAITINT**: CPSM waits for interrupt request

If this bit is set, the CPSM disables command timeout and waits for an interrupt request.

Bits 7:6 **WAITRESP**: Wait for response bits

They are used to configure whether the CPSM is to wait for a response, and if yes, which kind of response.

00: No response, expect CMDSENT flag

01: Short response, expect CMDREND or CCRCFAIL flag

10: No response, expect CMDSENT flag

11: Long response, expect CMDREND or CCRCFAIL flag

Bits 5:0 **CMDINDEX**: Command index

The command index is sent to the card as part of a command message.

- Note:**
- 1 After a data write, data cannot be written to this register for three SDMMCCLK clock periods plus two PCLK2 clock periods.
  - 2 MultiMediaCards can send two kinds of response: short responses, 48 bits long, or long responses, 136 bits long. SD card and SD I/O card can send only short responses, the argument can vary according to the type of response: the software will distinguish the type of response according to the sent command.

#### 45.8.5 SDMMC command response register (SDMMC\_RESPCMD)

Address offset: 0x10

Reset value: 0x0000 0000

The SDMMC\_RESPCMD register contains the command index field of the last command response received. If the command response transmission does not contain the command index field (long or OCR response), the RESPCMD field is unknown, although it must contain 111111b (the value of the reserved field from the response).

|      |      |      |      |      |      |      |      |      |      |         |      |      |      |      |      |
|------|------|------|------|------|------|------|------|------|------|---------|------|------|------|------|------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21      | 20   | 19   | 18   | 17   | 16   |

| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5       | 4    | 3    | 2    | 1    | 0    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | RESPCMD |      |      |      |      |      |
|      |      |      |      |      |      |      |      |      |      | r       | r    | r    | r    | r    | r    |

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:0 **RESPCMD**: Response command index

Read-only bit field. Contains the command index of the last command response received.

#### 45.8.6 SDMMC response 1..4 register (SDMMC\_RESPx)

Address offset: (0x10 + (4 × x)); x = 1..4

Reset value: 0x0000 0000

The SDMMC\_RESP1/2/3/4 registers contain the status of a card, which is part of the received response.

|                    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|--------------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31                 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| CARDSTATUSx[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| r                  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  |
| 15                 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| CARDSTATUSx[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| r                  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  |

Bits 31:0 **CARDSTATUSx**: see [Table 311](#).

The Card Status size is 32 or 127 bits, depending on the response type.

**Table 311. Response type and SDMMC\_RESPx registers**

| Register    | Short response    | Long response        |
|-------------|-------------------|----------------------|
| SDMMC_RESP1 | Card Status[31:0] | Card Status [127:96] |
| SDMMC_RESP2 | Unused            | Card Status [95:64]  |
| SDMMC_RESP3 | Unused            | Card Status [63:32]  |
| SDMMC_RESP4 | Unused            | Card Status [31:1]0b |

The most significant bit of the card status is received first. The SDMMC\_RESP4 register LSB is always 0b.

#### 45.8.7 SDMMC data timer register (SDMMC\_DTIMER)

Address offset: 0x24

Reset value: 0x0000 0000

The SDMMC\_DTIMER register contains the data timeout period, in card bus clock periods.

A counter loads the value from the SDMMC\_DTIMER register, and starts decrementing when the data path state machine (DPSM) enters the Wait\_R or Busy state. If the timer reaches 0 while the DPSM is in either of these states, the timeout status flag is set.

|                 |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31              | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| DATATIME[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw              | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
| 15              | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| DATATIME[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw              | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:0 **DATATIME**: Data timeout period

Data timeout period expressed in card bus clock periods.

**Note:** *A data transfer must be written to the data timer register and the data length register before being written to the data control register.*

## 45.8.8 SDMMC data length register (SDMMC\_DLEN)

Address offset: 0x28

Reset value: 0x0000 0000

The SDMMC\_DLEN register contains the number of data bytes to be transferred. The value is loaded into the data counter when data transfer starts.

|                  |      |      |      |      |      |      |                   |    |    |    |    |    |    |    |    |
|------------------|------|------|------|------|------|------|-------------------|----|----|----|----|----|----|----|----|
| 31               | 30   | 29   | 28   | 27   | 26   | 25   | 24                | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Res.             | Res. | Res. | Res. | Res. | Res. | Res. | DATALENGTH[24:16] |    |    |    |    |    |    |    |    |
|                  |      |      |      |      |      |      | rW                | rW | rW | rW | rW | rW | rW | rW | rW |
| 15               | 14   | 13   | 12   | 11   | 10   | 9    | 8                 | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| DATALENGTH[15:0] |      |      |      |      |      |      |                   |    |    |    |    |    |    |    |    |
| rW               | rW   | rW   | rW   | rW   | rW   | rW   | rW                | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 31:25 Reserved, must be kept at reset value.

Bits 24:0 **DATALENGTH**: Data length value

Number of data bytes to be transferred.

**Note:** For a block data transfer, the value in the data length register must be a multiple of the block size (see SDMMC\_DCTRL). Before being written to the data control register a timeout must be written to the data timer register and the data length register.

In case of IO\_RW\_EXTENDED (CMD53):

- If the Stream or SDIO multibyte data transfer is selected the value in the data length register must be between 1 and 512.

- If the Block data transfer is selected the value in the data length register must be between 1\*Data block size and 512\*Data block size.

## 45.8.9 SDMMC data control register (SDMMC\_DCTRL)

Address offset: 0x2C

Reset value: 0x0000 0000

The SDMMC\_DCTRL register control the data path state machine (DPSM).

|      |      |      |      |            |           |            |             |            |      |      |      |           |            |            |      |
|------|------|------|------|------------|-----------|------------|-------------|------------|------|------|------|-----------|------------|------------|------|

Bits 31:12 Reserved, must be kept at reset value.

Bit 11 **SDIOEN**: SD I/O enable functions

If this bit is set, the DPSM performs an SD I/O-card-specific operation.

Bit 10 **RWMOD**: Read wait mode

0: Read Wait control stopping SDMMC\_D2

1: Read Wait control using SDMMC\_CK

Bit 9 **RWSTOP**: Read wait stop

0: Read wait in progress if RWSTART bit is set

1: Enable for read wait stop if RWSTART bit is set

Bit 8 **RWSTART**: Read wait start

If this bit is set, read wait operation starts.

Bits 7:4 **DBLOCKSIZE**: Data block size

Define the data block length when the block data transfer mode is selected:

0000: (0 decimal) lock length =  $2^0$  = 1 byte

0001: (1 decimal) lock length =  $2^1$  = 2 bytes

0010: (2 decimal) lock length =  $2^2$  = 4 bytes

0011: (3 decimal) lock length =  $2^3$  = 8 bytes

0100: (4 decimal) lock length =  $2^4$  = 16 bytes

0101: (5 decimal) lock length =  $2^5$  = 32 bytes

0110: (6 decimal) lock length =  $2^6$  = 64 bytes

0111: (7 decimal) lock length =  $2^7$  = 128 bytes

1000: (8 decimal) lock length =  $2^8$  = 256 bytes

1001: (9 decimal) lock length =  $2^9$  = 512 bytes

1010: (10 decimal) lock length =  $2^{10}$  = 1024 bytes

1011: (11 decimal) lock length =  $2^{11}$  = 2048 bytes

1100: (12 decimal) lock length =  $2^{12}$  = 4096 bytes

1101: (13 decimal) lock length =  $2^{13}$  = 8192 bytes

1110: (14 decimal) lock length =  $2^{14}$  = 16384 bytes

1111: (15 decimal) reserved

Bit 3 **DMAEN**: DMA enable bit

0: DMA disabled.

1: DMA enabled.

Bit 2 **DTMODE**: Data transfer mode selection 1: Stream or SDIO multibyte data transfer.

0: Block data transfer

1: Stream or SDIO multibyte data transfer

Bit 1 **DTDIR**: Data transfer direction selection

0: From controller to card.

1: From card to controller.

[0] **DTEN**: Data transfer enabled bit

Data transfer starts if 1b is written to the DTEN bit. Depending on the direction bit, DTDIR, the DPSM moves to the Wait\_S, Wait\_R state or Readwait if RW Start is set immediately at the beginning of the transfer. It is not necessary to clear the enable bit after the end of a data transfer but the SDMMC\_DCTRL must be updated to enable a new data transfer

*Note: After a data write, data cannot be written to this register for three SDMMCCLK clock periods plus two PCLK2 clock periods.*

*The meaning of the DTMODE bit changes according to the value of the SDIOEN bit. When SDIOEN=0 and DTMODE=1, the MultiMediaCard stream mode is enabled, and when SDIOEN=1 and DTMODE=1, the peripheral enables an SDIO multibyte transfer.*

### 45.8.10 SDMMC data counter register (SDMMC\_DCOUNT)

Address offset: 0x30

Reset value: 0x0000 0000

The SDMMC\_DCOUNT register loads the value from the data length register (see SDMMC\_DLEN) when the DPSM moves from the Idle state to the Wait\_R or Wait\_S state. As data is transferred, the counter decrements the value until it reaches 0. The DPSM then moves to the Idle state and the data status end flag, DATAEND, is set.

Bits 31:25 Reserved, must be kept at reset value.

Bits 24:0 **DATACOUNT**: Data count value

When this bit is read, the number of remaining data bytes to be transferred is returned. Write has no effect.

*Note:* This register should be read only when the data transfer is complete.

### 45.8.11 SDMMC status register (SDMMC\_STA)

Address offset: 0x34

Reset value: 0x0000 0000

The SDMMC\_STA register is a read-only register. It contains two types of flag:

- Static flags (bits [23:22,10:0]): these bits remain asserted until they are cleared by writing to the SDMMC Interrupt Clear register (see SDMMC\_ICR)
- Dynamic flags (bits [21:11]): these bits change state depending on the state of the underlying logic (for example, FIFO full and empty flags are asserted and deasserted as data while written to the FIFO)

|          |          |       |       |         |          |      |          |          |          |          |           |           |           |           |           |

Bits 31:23 Reserved, must be kept at reset value.

Bit 22 **SDIOIT**: SDIO interrupt received

Bit 21 **RXDAVL**: Data available in receive FIFO

- Bit 20 **TXDAVL**: Data available in transmit FIFO
- Bit 19 **RXFIFOE**: Receive FIFO empty
- Bit 18 **TXFIFOE**: Transmit FIFO empty  
When HW Flow Control is enabled, TXFIFOE signals becomes activated when the FIFO contains 2 words.
- Bit 17 **RXFIFO**: Receive FIFO full  
When HW Flow Control is enabled, RXFIFO signals becomes activated 2 words before the FIFO is full.
- Bit 16 **TXFIFO**: Transmit FIFO full
- Bit 15 **RXFIFOH**: Receive FIFO half full: there are at least 8 words in the FIFO
- Bit 14 **TXFIFOH**: Transmit FIFO half empty: at least 8 words can be written into the FIFO
- Bit 13 **RXACT**: Data receive in progress
- Bit 12 **TXACT**: Data transmit in progress
- Bit 11 **CMDACT**: Command transfer in progress
- Bit 10 **DBCKEND**: Data block sent/received (CRC check passed)
- Bit 9 Reserved, must be kept at reset value.
- Bit 8 **DATAEND**: Data end (data counter, SDIDCOUNT, is zero)
- Bit 7 **CMDSENT**: Command sent (no response required)
- Bit 6 **CMDREND**: Command response received (CRC check passed)
- Bit 5 **RXOVERR**: Received FIFO overrun error  
*Note: If DMA is used to read SDMMC FIFO (DMAEN bit is set in SDMMC\_DCTRL register), user software should disable DMA stream, and then write with '0' (to disable DMA request generation).*
- Bit 4 **TXUNDERR**: Transmit FIFO underrun error  
*Note: If DMA is used to fill SDMMC FIFO (DMAEN bit is set in SDMMC\_DCTRL register), user software should disable DMA stream, and then write DMAEN with '0' (to disable DMA request generation).*
- Bit 3 **DTIMEOUT**: Data timeout
- Bit 2 **CTIMEOUT**: Command response timeout  
The Command TimeOut period has a fixed value of 64 SDMMC\_CLK clock periods.
- Bit 1 **DCRCFAIL**: Data block sent/received (CRC check failed)
- Bit 0 **CCRCFAIL**: Command response received (CRC check failed)

#### 45.8.12 SDMMC interrupt clear register (SDMMC\_ICR)

Address offset: 0x38

Reset value: 0x0000 0000

The SDMMC\_ICR register is a write-only register. Writing a bit with 1b clears the corresponding bit in the SDMMC\_STA Status register.

|      |      |      |      |      |           |      |           |           |            |            |             |            |            |            |            |

Bits 31:23 Reserved, must be kept at reset value.

Bit 22 **SDIOITC**: SDIOIT flag clear bit

Set by software to clear the SDIOIT flag.

0: SDIOIT not cleared

1: SDIOIT cleared

Bits 21:11 Reserved, must be kept at reset value.

Bit 10 **DBCKENDC**: DBCKEND flag clear bit

Set by software to clear the DBCKEND flag.

0: DBCKEND not cleared

1: DBCKEND cleared

Bit 9 Reserved, must be kept at reset value.

Bit 8 **DATAENDC**: DATAEND flag clear bit

Set by software to clear the DATAEND flag.

0: DATAEND not cleared

1: DATAEND cleared

Bit 7 **CMDSENTC**: CMDSENT flag clear bit

Set by software to clear the CMDSENT flag.

0: CMDSENT not cleared

1: CMDSENT cleared

Bit 6 **CMDREND C**: CMDREND flag clear bit

Set by software to clear the CMDREND flag.

0: CMDREND not cleared

1: CMDREND cleared

Bit 5 **RXOVERRC**: RXOVERR flag clear bit

Set by software to clear the RXOVERR flag.

0: RXOVERR not cleared

1: RXOVERR cleared

Bit 4 **TXUNDERRC**: TXUNDERR flag clear bit

Set by software to clear TXUNDERR flag.

0: TXUNDERR not cleared

1: TXUNDERR cleared

Bit 3 **DTIMEOUTC**: DTIMEOUT flag clear bit

Set by software to clear the DTIMEOUT flag.

0: DTIMEOUT not cleared

1: DTIMEOUT cleared

- Bit 2 **CTIMEOUTC**: CTIMEOUT flag clear bit  
Set by software to clear the CTIMEOUT flag.  
0: CTIMEOUT not cleared  
1: CTIMEOUT cleared
- Bit 1 **DCRCFAILC**: DCRCFAIL flag clear bit  
Set by software to clear the DCRCFAIL flag.  
0: DCRCFAIL not cleared  
1: DCRCFAIL cleared
- Bit 0 **CCRCFAILC**: CCRCFAIL flag clear bit  
Set by software to clear the CCRCFAIL flag.  
0: CCRCFAIL not cleared  
1: CCRCFAIL cleared

### 45.8.13 SDMMC mask register (SDMMC\_MASK)

Address offset: 0x3C

Reset value: 0x0000 0000

The interrupt mask register determines which status flags generate an interrupt request by setting the corresponding bit to 1b.

|                    |                    |             |             |              |               |      |               |                   |                   |                   |                    |                   |                   |                   |                   |

Bits 31:23 Reserved, must be kept at reset value.

- Bit 22 **SDIOITIE**: SDIO mode interrupt received interrupt enable  
Set and cleared by software to enable/disable the interrupt generated when receiving the SDIO mode interrupt.  
0: SDIO Mode Interrupt Received interrupt disabled  
1: SDIO Mode Interrupt Received interrupt enabled
- Bit 21 **RXDAVLIE**: Data available in Rx FIFO interrupt enable  
Set and cleared by software to enable/disable the interrupt generated by the presence of data available in Rx FIFO.  
0: Data available in Rx FIFO interrupt disabled  
1: Data available in Rx FIFO interrupt enabled
- Bit 20 **TXDAVLIE**: Data available in Tx FIFO interrupt enable  
Set and cleared by software to enable/disable the interrupt generated by the presence of data available in Tx FIFO.  
0: Data available in Tx FIFO interrupt disabled  
1: Data available in Tx FIFO interrupt enabled

- Bit 19 **RXFIFOEIE**: Rx FIFO empty interrupt enable  
Set and cleared by software to enable/disable interrupt caused by Rx FIFO empty.  
0: Rx FIFO empty interrupt disabled  
1: Rx FIFO empty interrupt enabled
- Bit 18 **TXFIFOEIE**: Tx FIFO empty interrupt enable  
Set and cleared by software to enable/disable interrupt caused by Tx FIFO empty.  
0: Tx FIFO empty interrupt disabled  
1: Tx FIFO empty interrupt enabled
- Bit 17 **RXFIFOIE**: Rx FIFO full interrupt enable  
Set and cleared by software to enable/disable interrupt caused by Rx FIFO full.  
0: Rx FIFO full interrupt disabled  
1: Rx FIFO full interrupt enabled
- Bit 16 **TXFIFOIE**: Tx FIFO full interrupt enable  
Set and cleared by software to enable/disable interrupt caused by Tx FIFO full.  
0: Tx FIFO full interrupt disabled  
1: Tx FIFO full interrupt enabled
- Bit 15 **RXFIFOHFIE**: Rx FIFO half full interrupt enable  
Set and cleared by software to enable/disable interrupt caused by Rx FIFO half full.  
0: Rx FIFO half full interrupt disabled  
1: Rx FIFO half full interrupt enabled
- Bit 14 **TXFIFOHEIE**: Tx FIFO half empty interrupt enable  
Set and cleared by software to enable/disable interrupt caused by Tx FIFO half empty.  
0: Tx FIFO half empty interrupt disabled  
1: Tx FIFO half empty interrupt enabled
- Bit 13 **RXACTIE**: Data receive acting interrupt enable  
Set and cleared by software to enable/disable interrupt caused by data being received (data receive acting).  
0: Data receive acting interrupt disabled  
1: Data receive acting interrupt enabled
- Bit 12 **TXACTIE**: Data transmit acting interrupt enable  
Set and cleared by software to enable/disable interrupt caused by data being transferred (data transmit acting).  
0: Data transmit acting interrupt disabled  
1: Data transmit acting interrupt enabled
- Bit 11 **CMDACTIE**: Command acting interrupt enable  
Set and cleared by software to enable/disable interrupt caused by a command being transferred (command acting).  
0: Command acting interrupt disabled  
1: Command acting interrupt enabled
- Bit 10 **DBCKENDIE**: Data block end interrupt enable  
Set and cleared by software to enable/disable interrupt caused by data block end.  
0: Data block end interrupt disabled  
1: Data block end interrupt enabled
- Bit 9 Reserved, must be kept at reset value.

- Bit 8 **DATAENDIE**: Data end interrupt enable  
 Set and cleared by software to enable/disable interrupt caused by data end.  
 0: Data end interrupt disabled  
 1: Data end interrupt enabled
- Bit 7 **CMDSENTIE**: Command sent interrupt enable  
 Set and cleared by software to enable/disable interrupt caused by sending command.  
 0: Command sent interrupt disabled  
 1: Command sent interrupt enabled
- Bit 6 **CMDRENDIE**: Command response received interrupt enable  
 Set and cleared by software to enable/disable interrupt caused by receiving command response.  
 0: Command response received interrupt disabled  
 1: command Response Received interrupt enabled
- Bit 5 **RXOVERRIE**: Rx FIFO overrun error interrupt enable  
 Set and cleared by software to enable/disable interrupt caused by Rx FIFO overrun error.  
 0: Rx FIFO overrun error interrupt disabled  
 1: Rx FIFO overrun error interrupt enabled
- Bit 4 **TXUNDERRIE**: Tx FIFO underrun error interrupt enable  
 Set and cleared by software to enable/disable interrupt caused by Tx FIFO underrun error.  
 0: Tx FIFO underrun error interrupt disabled  
 1: Tx FIFO underrun error interrupt enabled
- Bit 3 **DTIMEOUTIE**: Data timeout interrupt enable  
 Set and cleared by software to enable/disable interrupt caused by data timeout.  
 0: Data timeout interrupt disabled  
 1: Data timeout interrupt enabled
- Bit 2 **CTIMEOUTIE**: Command timeout interrupt enable  
 Set and cleared by software to enable/disable interrupt caused by command timeout.  
 0: Command timeout interrupt disabled  
 1: Command timeout interrupt enabled
- Bit 1 **DCRCFAILIE**: Data CRC fail interrupt enable  
 Set and cleared by software to enable/disable interrupt caused by data CRC failure.  
 0: Data CRC fail interrupt disabled  
 1: Data CRC fail interrupt enabled
- Bit 0 **CCRCFAILIE**: Command CRC fail interrupt enable  
 Set and cleared by software to enable/disable interrupt caused by command CRC failure.  
 0: Command CRC fail interrupt disabled  
 1: Command CRC fail interrupt enabled

#### 45.8.14 SDMMC FIFO counter register (SDMMC\_FIFOCNT)

Address offset: 0x48

Reset value: 0x0000 0000

The SDMMC\_FIFOCNT register contains the remaining number of words to be written to or read from the FIFO. The FIFO counter loads the value from the data length register (see SDMMC\_DLEN) when the data transfer enable bit, DTEN, is set in the data control register (SDMMC\_DCTRL register) and the DPSM is at the Idle state. If the data length is not word-aligned (multiple of 4), the remaining 1 to 3 bytes are regarded as a word.

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:0 **FIFOCOUNT**: Remaining number of words to be written to or read from the FIFO.

### 45.8.15 SDMMC data FIFO register (SDMMC\_FIFO)

Address offset: 0x80

Reset value: 0x0000 0000

The receive and transmit FIFOs can be read or written as 32-bit wide registers. The FIFOs contain 32 entries on 32 sequential addresses. This allows the CPU to use its load and store multiple operands to read from/write to the FIFO.

|                 |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

Refer to [Section 2.2 on page 75](#) for the register boundary addresses.

## 46 Controller area network (bxCAN)

### 46.1 Introduction

The **Basic Extended CAN** peripheral, named **bxCAN**, interfaces the CAN network. It supports the CAN protocols version 2.0A and B. It has been designed to manage a high number of incoming messages efficiently with a minimum CPU load. It also meets the priority requirements for transmit messages.

For safety-critical applications, the CAN controller provides all hardware functions for supporting the CAN Time Triggered Communication option.

### 46.2 bxCAN main features

- Supports CAN protocol version 2.0 A, B Active
- Bit rates up to 1 Mbit/s
- Supports the Time Triggered Communication option

#### Transmission

- Three transmit mailboxes
- Configurable transmit priority
- Time stamp on SOF transmission

#### Reception

- Two receive FIFOs with three stages
- Scalable filter banks:
  - 28 filter banks shared between CAN1 and CAN2 for dual CAN
  - 14 filter banks for single CAN
- Identifier list feature
- Configurable FIFO overrun
- Time stamp on SOF reception

#### Time-triggered communication option

- Disable automatic retransmission mode
- 16-bit free running timer
- Time stamp sent in last two data bytes

#### Management

- Maskable interrupts
- Software-efficient mailbox mapping at a unique address space

#### Dual CAN peripheral configuration

- CAN1: Master bxCAN for managing the communication between a Slave bxCAN and the 512-byte SRAM
- CAN2: Slave bxCAN, with no direct access to the SRAM.
- The two bxCAN cells share the 512-byte SRAM (see [Figure 516](#))  
See [Table 313](#).

Table 313. CAN implementation

| CAN feature   | STM32L47x/L48x | STM32L49x/L4Ax |
|---------------|----------------|----------------|
| Configuration | Single CAN     | Dual CAN       |

### 46.3 bxCAN general description

In today CAN applications, the number of nodes in a network is increasing and several networks are linked together via gateways. Typically, the number of messages in the system (to be handled by each node) has significantly increased. In addition to the application messages, network management and diagnostic messages have been introduced.

An enhanced filtering mechanism is required to handle each type of message.

Furthermore, application tasks require more CPU time, therefore real-time constraints caused by message reception must be reduced.

A receive FIFO scheme allows the CPU to be dedicated to application tasks for a long time period without losing messages.

The standard HLP (Higher Layer Protocol) based on standard CAN drivers requires an efficient interface to the CAN controller.

Figure 515. CAN network topology

#### 46.3.1 CAN 2.0B active core

The bxCAN module handles the transmission and the reception of CAN messages autonomously. Standard identifiers (11-bit) and extended identifiers (29-bit) are fully supported by hardware.

### 46.3.2 Control, status, and configuration registers

The application uses these registers to:

- Configure CAN parameters, for example baud rate
- Request transmissions
- Handle receptions
- Manage interrupts
- Get diagnostic information

### 46.3.3 Tx mailboxes

Three transmit mailboxes are provided to the software for setting up messages. The transmission scheduler decides which mailbox has to be transmitted first.

### 46.3.4 Acceptance filters

The bxCAN provides up to 28 scalable/configurable identifier filter banks in dual CAN configuration, or up to 14 scalable/configurable identifier filter banks in single CAN configuration, for selecting the incoming messages that the software needs, and discarding the others.

#### Receive FIFO

Two receive FIFOs are used by hardware to store the incoming messages. Three complete messages can be stored in each FIFO. The FIFOs are managed completely by hardware.

Figure 516. Dual-CAN block diagram

Figure 517. Single-CAN block diagram

## 46.4 bxCAN operating modes

bxCAN has three main operating modes: **initialization**, **normal**, and **Sleep**. After a hardware reset, bxCAN is in Sleep mode to reduce power consumption, and an internal pull-up is active on CANTX. The software requests bxCAN to enter **initialization** or **Sleep** mode by setting the INRQ or SLEEP bits in the CAN\_MCR register. Once the mode has been entered, bxCAN confirms it by setting the INAK or SLAK bits in the CAN\_MSR register, and the internal pull-up is disabled. When neither INAK nor SLAK is set, bxCAN is in **normal** mode. Before entering **normal** mode, bxCAN always must **synchronize** on the CAN bus. To synchronize, bxCAN waits until the CAN bus is idle, this means that 11 consecutive recessive bits have been monitored on CANRX.

### 46.4.1 Initialization mode

The software initialization can be done while the hardware is in Initialization mode. To enter this mode, the software sets the INRQ bit in the CAN\_MCR register and waits until the hardware has confirmed the request by setting the INAK bit in the CAN\_MSR register.

To leave Initialization mode, the software clears the INQR bit. bxCAN has left Initialization mode once the INAK bit has been cleared by hardware.

While in Initialization mode, all message transfers to and from the CAN bus are stopped and the status of the CAN bus output CANTX is recessive (high).

Entering Initialization mode does not change any of the configuration registers.

To initialize the CAN Controller, software has to set up the Bit timing (CAN\_BTR) and CAN options (CAN\_MCR) registers.

To initialize the registers associated with the CAN filter banks (mode, scale, FIFO assignment, activation, and filter values), software has to set the FINIT bit (CAN\_FMR). Filter initialization also can be done outside the initialization mode.

**Note:** When *FINIT=1*, CAN reception is deactivated.  
The filter values also can be modified by deactivating the associated filter activation bits (in the *CAN\_FA1R* register).  
If a filter bank is not used, it is recommended to leave it non active (leave the corresponding *FACT* bit cleared).

#### 46.4.2 Normal mode

Once the initialization is complete, the software must request the hardware to enter Normal mode to be able to synchronize on the CAN bus and start reception and transmission.

The request to enter Normal mode is issued by clearing the *INRQ* bit in the *CAN\_MCR* register. The bxCAN enters Normal mode and is ready to take part in bus activities when it has synchronized with the data transfer on the CAN bus. This is done by waiting for the occurrence of a sequence of 11 consecutive recessive bits (Bus Idle state). The switch to Normal mode is confirmed by the hardware by clearing the *INAK* bit in the *CAN\_MSR* register.

The initialization of the filter values is independent from Initialization mode but must be done while the filter is not active (corresponding *FACTx* bit cleared). The filter scale and mode configuration must be configured before entering Normal mode.

#### 46.4.3 Sleep mode (low-power)

To reduce power consumption, bxCAN has a low-power mode called Sleep mode. This mode is entered on software request by setting the *SLEEP* bit in the *CAN\_MCR* register. In this mode, the bxCAN clock is stopped, however software can still access the bxCAN mailboxes.

If software requests entry to **initialization** mode by setting the *INRQ* bit while bxCAN is in **Sleep** mode, it must also clear the *SLEEP* bit.

bxCAN can be woken up (exit Sleep mode) either by software clearing the *SLEEP* bit or on detection of CAN bus activity.

On CAN bus activity detection, hardware automatically performs the wake-up sequence by clearing the *SLEEP* bit if the *AWUM* bit in the *CAN\_MCR* register is set. If the *AWUM* bit is cleared, software has to clear the *SLEEP* bit when a wake-up interrupt occurs, in order to exit from Sleep mode.

**Note:** If the wake-up interrupt is enabled (*WKUIE* bit set in *CAN\_IER* register) a wake-up interrupt is generated on detection of CAN bus activity, even if the bxCAN automatically performs the wake-up sequence.

After the *SLEEP* bit has been cleared, Sleep mode is exited once bxCAN has synchronized with the CAN bus, refer to [Figure 518](#). The Sleep mode is exited once the *SLAK* bit has been cleared by hardware.

Figure 518. bxCAN operating modes

1. ACK = The wait state during which hardware confirms a request by setting the INAK or SLAK bits in the CAN\_MSR register.
2. SYNC = The state during which bxCAN waits until the CAN bus is idle, meaning 11 consecutive recessive bits have been monitored on CANRX.

## 46.5 Test mode

Test mode can be selected by the SILM and LBKM bits in the CAN\_BTR register. These bits must be configured while bxCAN is in Initialization mode. Once test mode has been selected, the INRQ bit in the CAN\_MCR register must be reset to enter Normal mode.

### 46.5.1 Silent mode

The bxCAN can be put in Silent mode by setting the SILM bit in the CAN\_BTR register.

In Silent mode, the bxCAN is able to receive valid data frames and valid remote frames, but sends only recessive bits on the CAN bus and cannot start a transmission. If the bxCAN has to send a dominant bit (ACK bit, overload flag, active error flag), the bit is rerouted internally so that the CAN Core monitors this dominant bit, although the CAN bus may remain in recessive state. Silent mode can be used to analyze the traffic on a CAN bus without affecting it by the transmission of dominant bits (Acknowledge bits, Error frames).

Figure 519. bxCAN in silent mode

### 46.5.2 Loop back mode

The bxCAN can be set in Loop back mode by setting the LBKM bit in the CAN\_BTR register. In Loop Back mode, the bxCAN treats its own transmitted messages as received messages and stores them (if they pass acceptance filtering) in a Receive mailbox.

Figure 520. bxCAN in Loop back mode

This mode is provided for self-test functions. To be independent of external events, the CAN Core ignores acknowledge errors (no dominant bit sampled in the acknowledge slot of a data / remote frame) in Loop back mode. In this mode, the bxCAN performs an internal feedback from its Tx output to its Rx input. The actual value of the CANRX input pin is disregarded by the bxCAN. The transmitted messages can be monitored on the CANTX pin.

### 46.5.3 Loop back combined with silent mode

It is also possible to combine Loop back mode and Silent mode by setting the LBKM and SILM bits in the CAN\_BTR register. This mode can be used for a “Hot Selftest”, meaning the bxCAN can be tested like in Loop back mode but without affecting a running CAN system connected to the CANTX and CANRX pins. In this mode, the CANRX pin is disconnected from the bxCAN and the CANTX pin is held recessive.

Figure 521. bxCAN in combined mode

MS30395V2

## 46.6 Behavior in debug mode

When the microcontroller enters the debug mode (Cortex®-M4 core halted), the bxCAN continues to work normally or stops, depending on:

- the DBG\_CAN1\_STOP bit for CAN1 or the DBG\_CAN2\_STOP bit for CAN2 in the DBG module for the dual mode.
- the DBG\_CAN1\_STOP bit in the DBG module for the single mode.
- the DBF bit in CAN\_MCR. For more details, refer to [Section 46.9.2: CAN control and status registers](#).

## 46.7 bxCAN functional description

### 46.7.1 Transmission handling

To transmit a message, the application must select one **empty** transmit mailbox, set up the identifier, the data length code (DLC), and the data before requesting the transmission by setting the corresponding TXRQ bit in the CAN\_TiRx register. Once the mailbox has left **empty** state, the software no longer has write access to the mailbox registers. Immediately after the TXRQ bit has been set, the mailbox enters **pending** state and waits to become the highest priority mailbox, see *Transmit Priority*. As soon as the mailbox has the highest priority it is **scheduled** for transmission. The transmission of the message of the scheduled mailbox starts (enter **transmit** state) when the CAN bus becomes idle. Once the mailbox has been successfully transmitted, it becomes **empty** again. The hardware indicates a successful transmission by setting the RQCP and TXOK bits in the CAN\_TSR register.

If the transmission fails, the cause is indicated by the ALST bit in the CAN\_TSR register in case of an Arbitration Lost, and/or the TERR bit, in case of transmission error detection.

#### Transmit priority

- By identifier  
When more than one transmit mailbox is pending, the transmission order is given by the identifier of the message stored in the mailbox. The message with the lowest identifier value has the highest priority according to the arbitration of the

CAN protocol. If the identifier values are equal, the lower mailbox number is scheduled first.

- By transmit request order

The transmit mailboxes can be configured as a transmit FIFO by setting the TXFP bit in the CAN\_MCR register. In this mode, the priority order is given by the transmit request order. This mode is very useful for segmented transmission.

### Abort

A transmission request can be aborted by the user setting the ABRQ bit in the CAN\_TSR register. In **pending** or **scheduled** state, the mailbox is aborted immediately. An abort request while the mailbox is in **transmit** state can have two results. If the mailbox is transmitted successfully the mailbox becomes **empty** with the TXOK bit set in the CAN\_TSR register. If the transmission fails, the mailbox becomes **scheduled**, the transmission is aborted and becomes **empty** with TXOK cleared. In all cases, the mailbox becomes **empty** again at least at the end of the current transmission.

### Non automatic retransmission mode

This mode has been implemented in order to fulfill the requirement of the Time Triggered Communication option of the CAN standard. To configure the hardware in this mode the NART bit in the CAN\_MCR register must be set.

In this mode, each transmission is started only once. If the first attempt fails, due to an arbitration loss or an error, the hardware does not automatically restart the message transmission.

At the end of the first transmission attempt, the hardware considers the request as completed and sets the RQCP bit in the CAN\_TSR register. The result of the transmission is indicated in the CAN\_TSR register by the TXOK, ALST, and TERR bits.

**Figure 522. Transmit mailbox states**

### 46.7.2 Time triggered communication mode

In this mode, the internal counter of the CAN hardware is activated and used to generate the time stamp value stored in the CAN\_RDTxR/CAN\_TDTxR registers, respectively (for Rx and Tx mailboxes). The internal counter is incremented each CAN bit time (refer to [Section 46.7.7](#)). The internal counter is captured on the sample point of the Start Of Frame bit in both reception and transmission.

### 46.7.3 Reception handling

For the reception of CAN messages, three mailboxes organized as a FIFO are provided. In order to save CPU load, simplify the software and guarantee data consistency, the FIFO is managed completely by hardware. The application accesses the messages stored in the FIFO through the FIFO output mailbox.

#### Valid message

A received message is considered as valid **when** it has been received correctly according to the CAN protocol (no error until the last but one bit of the EOF field) **and** It passed through the identifier filtering successfully, see [Section 46.7.4](#).

Figure 523. Receive FIFO states

## FIFO management

Starting from the **empty** state, the first valid message received is stored in the FIFO, which becomes **pending\_1**. The hardware signals the event setting the FMP[1:0] bits in the CAN\_RFR register to the value 01b. The message is available in the FIFO output mailbox. The software reads out the mailbox content and releases it by setting the RFOM bit in the CAN\_RFR register. The FIFO becomes **empty** again. If a new valid message has been received in the meantime, the FIFO stays in **pending\_1** state, and the new message is available in the output mailbox.

If the application does not release the mailbox, the next valid message is stored in the FIFO, which enters **pending\_2** state (FMP[1:0] = 10b). The storage process is repeated for the next valid message putting the FIFO into **pending\_3** state (FMP[1:0] = 11b). At this point, the software must release the output mailbox by setting the RFOM bit, so that a mailbox is free to store the next valid message. Otherwise, the next valid message received causes a loss of message. Refer also to [Section 46.7.5](#).

## Overrun

Once the FIFO is in **pending\_3** state (the three mailboxes are full) the next valid message reception leads to an **overrun**, and a message is lost. The hardware signals the overrun condition by setting the FOVR bit in the CAN\_RFR register. Which message is lost depends on the configuration of the FIFO:

- If the FIFO lock function is disabled (RFLM bit in the CAN\_MCR register cleared) the last message stored in the FIFO is overwritten by the new incoming message. In this case, the latest messages are always available to the application.
- If the FIFO lock function is enabled (RFLM bit in the CAN\_MCR register set) the most recent message is discarded, and the software has the three oldest messages in the FIFO available.

## Reception related interrupts

Once a message has been stored in the FIFO, the FMP[1:0] bits are updated, and an interrupt request is generated if the FMPIE bit in the CAN\_IER register is set.

When the FIFO becomes full (a third message is stored) the FULL bit in the CAN\_RFR register is set, and an interrupt is generated if the FFIE bit in the CAN\_IER register is set.

On overrun condition, the FOVR bit is set and an interrupt is generated if the FOVIE bit in the CAN\_IER register is set.

### 46.7.4 Identifier filtering

In the CAN protocol the identifier of a message is not associated with the address of a node but related to the content of the message. Consequently, a transmitter broadcasts its message to all receivers. On message reception a receiver node decides - depending on the identifier value - whether the software needs the message or not. If the message is needed, it is copied into the SRAM. If not, the message must be discarded without intervention by the software.

To fulfill this requirement in dual CAN configuration, bxCAN Controller provides 28 configurable and scalable filter banks (27-0) to the application. In single CAN configuration bxCAN Controller provides 14 configurable and scalable filter banks (13-0) to the application in order to receive only the messages the software needs.

This hardware filtering saves CPU resources which would be otherwise needed to perform filtering by software. Each filter bank *x* consists of two 32-bit registers, CAN\_FxR0 and CAN\_FxR1.

### Scalable width

To optimize and adapt the filters to the application needs, each filter bank can be scaled independently. Depending on the filter scale, a filter bank provides:

- One 32-bit filter for the STDID[10:0], EXTID[17:0], IDE, and RTR bits.
- Two 16-bit filters for the STDID[10:0], RTR, IDE, and EXTID[17:15] bits.

Refer to [Figure 524](#).

Furthermore, the filters can be configured in mask mode or in identifier list mode.

### Mask mode

In **mask** mode the identifier registers are associated with mask registers specifying which bits of the identifier are handled as “must match” or as “don’t care”.

### Identifier list mode

In **identifier list** mode, the mask registers are used as identifier registers. Thus, instead of defining an identifier and a mask, two identifiers are specified, doubling the number of single identifiers. All bits of the incoming identifier must match the bits specified in the filter registers.

### Filter bank scale and mode configuration

The filter banks are configured by means of the corresponding CAN\_FMR register. To configure a filter bank, it must be deactivated by clearing the FACT bit in the CAN\_FAR register. The filter scale is configured by means of the corresponding FSCx bit in the CAN\_FS1R register, refer to [Figure 524](#). The **identifier list** or **identifier mask** mode for the corresponding Mask/Identifier registers is configured by means of the FBMx bits in the CAN\_FMR register.

To filter a group of identifiers, configure the Mask/Identifier registers in mask mode.

To select single identifiers, configure the Mask/Identifier registers in identifier list mode.

Filters not used by the application should be left deactivated.

Each filter within a filter bank is numbered (called the *Filter number*) from 0 to a maximum dependent on the mode and the scale of each of the filter banks.

Concerning the filter configuration, refer to [Figure 524](#).

Figure 524. Filter bank scale configuration - Register organization

## Filter match index

Once a message has been received in the FIFO it is available to the application. Typically, application data is copied into SRAM locations. To copy the data to the right location the application has to identify the data by means of the identifier. To avoid this, and to ease the access to the SRAM locations, the CAN controller provides a filter match index.

This index is stored in the mailbox together with the message according to the filter priority rules. Thus each received message has its associated filter match index.

The filter match index can be used in two ways:

- Compare the filter match index with a list of expected values.
- Use the filter match index as an index on an array to access the data destination location.

For non masked filters, the software no longer has to compare the identifier.

If the filter is masked the software reduces the comparison to the masked bits only.

The index value of the filter number does not take into account the activation state of the filter banks. In addition, two independent numbering schemes are used, one for each FIFO. Refer to [Figure 525](#) for an example.

Figure 525. Example of filter numbering

### Filter priority rules

Depending on the filter combination it may occur that an identifier passes successfully through several filters. In this case the filter match value stored in the receive mailbox is chosen according to the following priority rules:

- A 32-bit filter takes priority over a 16-bit filter.
- For filters of equal scale, priority is given to the Identifier List mode over the Identifier Mask mode
- For filters of equal scale and mode, priority is given by the filter number (the lower the number, the higher the priority).

Figure 526. Filtering mechanism example

The example above shows the filtering principle of the bxCAN. On reception of a message, the identifier is compared first with the filters configured in identifier list mode. If there is a match, the message is stored in the associated FIFO and the index of the matching filter is stored in the filter match index. As shown in the example, the identifier matches with Identifier #2 thus the message content and FMI 2 is stored in the FIFO.

If there is no match, the incoming identifier is then compared with the filters configured in mask mode.

If the identifier does not match any of the identifiers configured in the filters, the message is discarded by hardware without disturbing the software.

### 46.7.5 Message storage

The interface between the software and the hardware for the CAN messages is implemented by means of mailboxes. A mailbox contains all information related to a message; identifier, data, control, status and time stamp information.

#### Transmit mailbox

The software sets up the message to be transmitted in an empty transmit mailbox. The status of the transmission is indicated by hardware in the CAN\_TSR register.

Table 314. Transmit mailbox mapping

| Offset to transmit mailbox base address | Register name |
|-----------------------------------------|---------------|
| 0                                       | CAN_TlRxR     |
| 4                                       | CAN_TDTxR     |
| 8                                       | CAN_TDLxR     |
| 12                                      | CAN_TDHxR     |

### Receive mailbox

When a message has been received, it is available to the software in the FIFO output mailbox. Once the software has handled the message (e.g. read it) the software must release the FIFO output mailbox by means of the RFOM bit in the CAN\_RFR register to make the next incoming message available. The filter match index is stored in the MFMI field of the CAN\_RDTxR register. The 16-bit time stamp value is stored in the TIME[15:0] field of CAN\_RDTxR.

Table 315. Receive mailbox mapping

| Offset to receive mailbox base address (bytes) | Register name |
|------------------------------------------------|---------------|
| 0                                              | CAN_RlRxR     |
| 4                                              | CAN_RDTxR     |
| 8                                              | CAN_RDLxR     |
| 12                                             | CAN_RDHxR     |

Figure 527. CAN error state diagram

## 46.7.6 Error management

The error management as described in the CAN protocol is handled entirely by hardware using a Transmit Error Counter (TEC value, in CAN\_ESR register) and a Receive Error Counter (REC value, in the CAN\_ESR register), which get incremented or decremented according to the error condition. For detailed information about TEC and REC management, refer to the CAN standard.

Both of them may be read by software to determine the stability of the network. Furthermore, the CAN hardware provides detailed information on the current error status in CAN\_ESR register. By means of the CAN\_IER register (ERRIE bit, etc.), the software can configure the interrupt generation on error detection in a very flexible way.

### Bus-Off recovery

The Bus-Off state is reached when TEC is greater than 255, this state is indicated by BOFF bit in CAN\_ESR register. In Bus-Off state, the bxCAN is no longer able to transmit and receive messages.

Depending on the ABOM bit in the CAN\_MCR register, bxCAN recovers from Bus-Off (become error active again) either automatically or on software request. But in both cases the bxCAN has to wait at least for the recovery sequence specified in the CAN standard (128 occurrences of 11 consecutive recessive bits monitored on CANRX).

If ABOM is set, the bxCAN starts the recovering sequence automatically after it has entered Bus-Off state.

If ABOM is cleared, the software must initiate the recovering sequence, by requesting bxCAN to enter and to leave initialization mode.

*Note:* In initialization mode, bxCAN does not monitor the CANRX signal, therefore it cannot complete the recovery sequence. **To recover, bxCAN must be in normal mode.**

### 46.7.7 Bit timing

The bit timing logic monitors the serial bus-line and performs sampling and adjustment of the sample point by synchronizing on the start-bit edge and resynchronizing on the following edges.

Its operation may be explained simply by splitting nominal bit time into three segments as follows:

- **Synchronization segment (SYNC\_SEG):** a bit change is expected to occur within this time segment. It has a fixed length of one time quantum ( $1 \times t_q$ ).
- **Bit segment 1 (BS1):** defines the location of the sample point. It includes the PROP\_SEG and PHASE\_SEG1 of the CAN standard. Its duration is programmable between 1 and 16 time quanta but may be automatically lengthened to compensate for positive phase drifts due to differences in the frequency of the various nodes of the network.
- **Bit segment 2 (BS2):** defines the location of the transmit point. It represents the PHASE\_SEG2 of the CAN standard. Its duration is programmable between 1 and 8 time quanta but may also be automatically shortened to compensate for negative phase drifts.

The resynchronization jump width (SJW) defines an upper bound to the amount of lengthening or shortening of the bit segments. It is programmable between 1 and 4 time quanta.

A valid edge is defined as the first transition in a bit time from dominant to recessive bus level provided the controller itself does not send a recessive bit.

If a valid edge is detected in BS1 instead of SYNC\_SEG, BS1 is extended by up to SJW so that the sample point is delayed.

Conversely, if a valid edge is detected in BS2 instead of SYNC\_SEG, BS2 is shortened by up to SJW so that the transmit point is moved earlier.

As a safeguard against programming errors, the configuration of the Bit timing register (CAN\_BTR) is only possible while the device is in Standby mode.

*Note:* For a detailed description of the CAN bit timing and resynchronization mechanism, refer to the ISO 11898 standard.

**Figure 528. Bit timing**

Figure 529. CAN frames

## 46.8 bxCAN interrupts

Four interrupt vectors are dedicated to bxCAN. Each interrupt source can be independently enabled or disabled by means of the CAN interrupt enable register (CAN\_IER).

**Figure 530. Event flags and interrupt generation**

- The **transmit interrupt** can be generated by the following events:
  - Transmit mailbox 0 becomes empty, RQCP0 bit in the CAN\_TSR register set.
  - Transmit mailbox 1 becomes empty, RQCP1 bit in the CAN\_TSR register set.
  - Transmit mailbox 2 becomes empty, RQCP2 bit in the CAN\_TSR register set.
- The **FIFO 0 interrupt** can be generated by the following events:
  - Reception of a new message, FMP0 bits in the CAN\_RF0R register are not '00'.
  - FIFO0 full condition, FULL0 bit in the CAN\_RF0R register set.
  - FIFO0 overrun condition, FOVR0 bit in the CAN\_RF0R register set.
- The **FIFO 1 interrupt** can be generated by the following events:
  - Reception of a new message, FMP1 bits in the CAN\_RF1R register are not '00'.
  - FIFO1 full condition, FULL1 bit in the CAN\_RF1R register set.
  - FIFO1 overrun condition, FOVR1 bit in the CAN\_RF1R register set.
- The **error and status change interrupt** can be generated by the following events:
  - Error condition, for more details on error conditions refer to the CAN Error Status register (CAN\_ESR).
  - Wake-up condition, SOF monitored on the CAN Rx signal.
  - Entry into Sleep mode.

## 46.9 CAN registers

The peripheral registers must be accessed by words (32 bits).

### 46.9.1 Register access protection

Erroneous access to certain configuration registers can cause the hardware to temporarily disturb the whole CAN network. Therefore, the CAN\_BTR register can be modified by software only while the CAN hardware is in initialization mode.

Although the transmission of incorrect data does not cause problems at the CAN network level, it can severely disturb the application. A transmit mailbox can be only modified by software while it is in empty state, refer to [Figure 522: Transmit mailbox states](#).

The filter values can be modified either deactivating the associated filter banks or by setting the FINIT bit. Moreover, the modification of the filter configuration (scale, mode, and FIFO assignment) in CAN\_FMR, CAN\_FSxR and CAN\_FFAR registers can only be done when the filter initialization mode is set (FINIT=1) in the CAN\_FMR register.

### 46.9.2 CAN control and status registers

Refer to [Section 1.2](#) for a list of abbreviations used in register descriptions.

#### CAN master control register (CAN\_MCR)

Address offset: 0x00

| rs    |      |      |      |      |      |      |      | rw   | rw   | rw   | rw   | rw   | rw   | rw    | rw   |

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **DBF**: Debug freeze

0: CAN working during debug

1: CAN reception/transmission frozen during debug. Reception FIFOs can still be accessed/controlled normally.

Bit 15 **RESET**: bxCAN software master reset

0: Normal operation.

1: Force a master reset of the bxCAN -> Sleep mode activated after reset (FMP bits and CAN\_MCR register are initialized to the reset values). This bit is automatically reset to 0.

Bits 14:8 Reserved, must be kept at reset value.

Bit 7 **TTCM**: Time triggered communication mode

0: Time Triggered Communication mode disabled.

1: Time Triggered Communication mode enabled

*Note: For more information on Time Triggered Communication mode, refer to [Section 46.7.2: Time triggered communication mode](#).*

Bit 6 **ABOM**: Automatic bus-off management

This bit controls the behavior of the CAN hardware on leaving the Bus-Off state.

0: The Bus-Off state is left on software request, once 128 occurrences of 11 recessive bits have been monitored and the software has first set and cleared the INRQ bit of the CAN\_MCR register.

1: The Bus-Off state is left automatically by hardware once 128 occurrences of 11 recessive bits have been monitored.

For detailed information on the Bus-Off state refer to [Section 46.7.6: Error management](#).

Bit 5 **AWUM**: Automatic wake-up mode

This bit controls the behavior of the CAN hardware on message reception during Sleep mode.

0: The Sleep mode is left on software request by clearing the SLEEP bit of the CAN\_MCR register.

1: The Sleep mode is left automatically by hardware on CAN message detection.

The SLEEP bit of the CAN\_MCR register and the SLAK bit of the CAN\_MSR register are cleared by hardware.

Bit 4 **NART**: No automatic retransmission

0: The CAN hardware automatically retransmits the message until it has been successfully transmitted according to the CAN standard.

1: A message is transmitted only once, independently of the transmission result (successful, error or arbitration lost).

Bit 3 **RFLM**: Receive FIFO locked mode

0: Receive FIFO not locked on overrun. Once a receive FIFO is full the next incoming message overwrites the previous one.

1: Receive FIFO locked against overrun. Once a receive FIFO is full the next incoming message is discarded.

Bit 2 **TXFP**: Transmit FIFO priority

This bit controls the transmission order when several mailboxes are pending at the same time.

0: Priority driven by the identifier of the message

1: Priority driven by the request order (chronologically)

Bit 1 **SLEEP**: Sleep mode request

This bit is set by software to request the CAN hardware to enter the Sleep mode. Sleep mode is entered as soon as the current CAN activity (transmission or reception of a CAN frame) has been completed.

This bit is cleared by software to exit Sleep mode.

This bit is cleared by hardware when the AWUM bit is set and a SOF bit is detected on the CAN Rx signal.

This bit is set after reset - CAN starts in Sleep mode.

Bit 0 **INRQ**: Initialization request

The software clears this bit to switch the hardware into normal mode. Once 11 consecutive recessive bits have been monitored on the Rx signal the CAN hardware is synchronized and ready for transmission and reception. Hardware signals this event by clearing the INAK bit in the CAN\_MSR register.

Software sets this bit to request the CAN hardware to enter initialization mode. Once software has set the INRQ bit, the CAN hardware waits until the current CAN activity (transmission or reception) is completed before entering the initialization mode. Hardware signals this event by setting the INAK bit in the CAN\_MSR register.

|      |      |      |      | r    | r    | r    | r    |      |      |      | rc_w1 | rc_w1 | rc_w1 | r    | r    |

Bits 31:12 Reserved, must be kept at reset value.

Bit 11 **RX**: CAN Rx signal

Monitors the actual value of the **CAN\_RX** Pin.

Bit 10 **SAMP**: Last sample point

The value of RX on the last sample point (current received bit value).

Bit 9 **RXM**: Receive mode

The CAN hardware is currently receiver.

Bit 8 **TXM**: Transmit mode

The CAN hardware is currently transmitter.

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **SLAKI**: Sleep acknowledge interrupt

When SLKIE=1, this bit is set by hardware to signal that the bxCAN has entered Sleep mode. When set, this bit generates a status change interrupt if the SLKIE bit in the CAN\_IER register is set.

This bit is cleared by software or by hardware, when SLAK is cleared.

*Note: When SLKIE=0, no polling on SLAKI is possible. In this case the SLAK bit can be polled.*

Bit 3 **WKUI**: Wake-up interrupt

This bit is set by hardware to signal that a SOF bit has been detected while the CAN hardware was in Sleep mode. Setting this bit generates a status change interrupt if the WKUIE bit in the CAN\_IER register is set.

This bit is cleared by software.

Bit 2 **ERRI**: Error interrupt

This bit is set by hardware when a bit of the CAN\_ESR has been set on error detection and the corresponding interrupt in the CAN\_IER is enabled. Setting this bit generates a status change interrupt if the ERRIE bit in the CAN\_IER register is set.

This bit is cleared by software.

Bit 1 **SLAK**: Sleep acknowledge

This bit is set by hardware and indicates to the software that the CAN hardware is now in Sleep mode. This bit acknowledges the Sleep mode request from the software (set SLEEP bit in CAN\_MCR register).

This bit is cleared by hardware when the CAN hardware has left Sleep mode (to be synchronized on the CAN bus). To be synchronized the hardware has to monitor a sequence of 11 consecutive recessive bits on the CAN RX signal.

*Note: The process of leaving Sleep mode is triggered when the SLEEP bit in the CAN\_MCR register is cleared. Refer to the AWUM bit of the CAN\_MCR register description for detailed information for clearing SLEEP bit*

Bit 0 **INAK**: Initialization acknowledge

This bit is set by hardware and indicates to the software that the CAN hardware is now in initialization mode. This bit acknowledges the initialization request from the software (set INRQ bit in CAN\_MCR register).

This bit is cleared by hardware when the CAN hardware has left the initialization mode (to be synchronized on the CAN bus). To be synchronized the hardware has to monitor a sequence of 11 consecutive recessive bits on the CAN RX signal.

### CAN transmit status register (CAN\_TSR)

Address offset: 0x08

Reset value: 0x1C00 0000

|       |      |      |      |       |       |           |       |       |      |      |      |       |       |       |       |

Bit 31 **LOW2**: Lowest priority flag for mailbox 2

This bit is set by hardware when more than one mailbox are pending for transmission and mailbox 2 has the lowest priority.

Bit 30 **LOW1**: Lowest priority flag for mailbox 1

This bit is set by hardware when more than one mailbox are pending for transmission and mailbox 1 has the lowest priority.

Bit 29 **LOW0**: Lowest priority flag for mailbox 0

This bit is set by hardware when more than one mailbox are pending for transmission and mailbox 0 has the lowest priority.

*Note: The LOW[2:0] bits are set to 0 when only one mailbox is pending.*

Bit 28 **TME2**: Transmit mailbox 2 empty

This bit is set by hardware when no transmit request is pending for mailbox 2.

Bit 27 **TME1**: Transmit mailbox 1 empty

This bit is set by hardware when no transmit request is pending for mailbox 1.

Bit 26 **TME0**: Transmit mailbox 0 empty

This bit is set by hardware when no transmit request is pending for mailbox 0.

Bits 25:24 **CODE[1:0]**: Mailbox code

In case at least one transmit mailbox is free, the code value is equal to the number of the next transmit mailbox free.

In case all transmit mailboxes are pending, the code value is equal to the number of the transmit mailbox with the lowest priority.

Bit 23 **ABRQ2**: Abort request for mailbox 2

Set by software to abort the transmission request for the corresponding mailbox.

Cleared by hardware when the mailbox becomes empty.

Setting this bit has no effect when the mailbox is not pending for transmission.

Bits 22:20 Reserved, must be kept at reset value.

Bit 19 **TERR2**: Transmission error of mailbox 2

This bit is set when the previous TX failed due to an error.

Bit 18 **ALST2**: Arbitration lost for mailbox 2

This bit is set when the previous TX failed due to an arbitration lost.

Bit 17 **TXOK2**: Transmission OK of mailbox 2

The hardware updates this bit after each transmission attempt.

0: The previous transmission failed

1: The previous transmission was successful

This bit is set by hardware when the transmission request on mailbox 2 has been completed successfully. Refer to [Figure 522](#).

- Bit 16 **RQCP2**: Request completed mailbox2  
Set by hardware when the last request (transmit or abort) has been performed.  
Cleared by software writing a “1” or by hardware on transmission request (TXRQ2 set in CAN\_TMD2R register).  
Clearing this bit clears all the status bits (TXOK2, ALST2 and TERR2) for Mailbox 2.
- Bit 15 **ABRQ1**: Abort request for mailbox 1  
Set by software to abort the transmission request for the corresponding mailbox.  
Cleared by hardware when the mailbox becomes empty.  
Setting this bit has no effect when the mailbox is not pending for transmission.
- Bits 14:12 Reserved, must be kept at reset value.
- Bit 11 **TERR1**: Transmission error of mailbox1  
This bit is set when the previous TX failed due to an error.
- Bit 10 **ALST1**: Arbitration lost for mailbox1  
This bit is set when the previous TX failed due to an arbitration lost.
- Bit 9 **TXOK1**: Transmission OK of mailbox1  
The hardware updates this bit after each transmission attempt.  
0: The previous transmission failed  
1: The previous transmission was successful  
This bit is set by hardware when the transmission request on mailbox 1 has been completed successfully. Refer to [Figure 522](#).
- Bit 8 **RQCP1**: Request completed mailbox1  
Set by hardware when the last request (transmit or abort) has been performed.  
Cleared by software writing a “1” or by hardware on transmission request (TXRQ1 set in CAN\_TI1R register).  
Clearing this bit clears all the status bits (TXOK1, ALST1 and TERR1) for Mailbox 1.
- Bit 7 **ABRQ0**: Abort request for mailbox0  
Set by software to abort the transmission request for the corresponding mailbox.  
Cleared by hardware when the mailbox becomes empty.  
Setting this bit has no effect when the mailbox is not pending for transmission.
- Bits 6:4 Reserved, must be kept at reset value.
- Bit 3 **TERR0**: Transmission error of mailbox0  
This bit is set when the previous TX failed due to an error.
- Bit 2 **ALST0**: Arbitration lost for mailbox0  
This bit is set when the previous TX failed due to an arbitration lost.
- Bit 1 **TXOK0**: Transmission OK of mailbox0  
The hardware updates this bit after each transmission attempt.  
0: The previous transmission failed  
1: The previous transmission was successful  
This bit is set by hardware when the transmission request on mailbox 1 has been completed successfully. Refer to [Figure 522](#).
- Bit 0 **RQCP0**: Request completed mailbox0  
Set by hardware when the last request (transmit or abort) has been performed.  
Cleared by software writing a “1” or by hardware on transmission request (TXRQ0 set in CAN\_TI0R register).  
Clearing this bit clears all the status bits (TXOK0, ALST0 and TERR0) for Mailbox 0.

**CAN receive FIFO 0 register (CAN\_RF0R)**

Address offset: 0x0C

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |      |       |       |       |      |           |      |

| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | RFOM0 | FOVR0 | FULL0 | Res. | FMP0[1:0] |      |
|      |      |      |      |      |      |      |      |      |      | rs    | rc_w1 | rc_w1 |      | r         | r    |

Bits 31:6 Reserved, must be kept at reset value.

Bit 5 **RFOM0**: Release FIFO 0 output mailbox

Set by software to release the output mailbox of the FIFO. The output mailbox can only be released when at least one message is pending in the FIFO. Setting this bit when the FIFO is empty has no effect. If at least two messages are pending in the FIFO, the software has to release the output mailbox to access the next message.

Cleared by hardware when the output mailbox has been released.

Bit 4 **FOVR0**: FIFO 0 overrun

This bit is set by hardware when a new message has been received and passed the filter while the FIFO was full.

This bit is cleared by software.

Bit 3 **FULL0**: FIFO 0 full

Set by hardware when three messages are stored in the FIFO.

This bit is cleared by software.

Bit 2 Reserved, must be kept at reset value.

Bits 1:0 **FMP0[1:0]**: FIFO 0 message pending

These bits indicate how many messages are pending in the receive FIFO.

FMP is increased each time the hardware stores a new message in to the FIFO. FMP is decreased each time the software releases the output mailbox by setting the RFOM0 bit.

**CAN receive FIFO 1 register (CAN\_RF1R)**

Address offset: 0x10

|      |      |      |      |      |      |      |      |      |      | rs    | rc_w1 | rc_w1 |      | r         | r    |

Bits 31:6 Reserved, must be kept at reset value.

Bit 5 **RFOM1**: Release FIFO 1 output mailbox

Set by software to release the output mailbox of the FIFO. The output mailbox can only be released when at least one message is pending in the FIFO. Setting this bit when the FIFO is empty has no effect. If at least two messages are pending in the FIFO, the software has to release the output mailbox to access the next message.

Cleared by hardware when the output mailbox has been released.

Bit 4 **FOVR1**: FIFO 1 overrun

This bit is set by hardware when a new message has been received and passed the filter while the FIFO was full.

This bit is cleared by software.

Bit 3 **FULL1**: FIFO 1 full

Set by hardware when three messages are stored in the FIFO.

This bit is cleared by software.

Bit 2 Reserved, must be kept at reset value.

Bits 1:0 **FMP1[1:0]**: FIFO 1 message pending

These bits indicate how many messages are pending in the receive FIFO1.

FMP1 is increased each time the hardware stores a new message in to the FIFO1. FMP is decreased each time the software releases the output mailbox by setting the RFOM1 bit.

### CAN interrupt enable register (CAN\_IER)

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **SLKIE**: Sleep interrupt enable

0: No interrupt when SLAKI bit is set.

1: Interrupt generated when SLAKI bit is set.

Bit 16 **WKUIE**: Wake-up interrupt enable

0: No interrupt when WKUI is set.

1: Interrupt generated when WKUI bit is set.

Bit 15 **ERRIE**: Error interrupt enable

0: No interrupt is generated when an error condition is pending in the CAN\_ESR.

1: An interrupt is generation when an error condition is pending in the CAN\_ESR.

Bits 14:12 Reserved, must be kept at reset value.

- Bit 11 **LECIE**: Last error code interrupt enable  
0: ERRI bit is not set when the error code in LEC[2:0] is set by hardware on error detection.  
1: ERRI bit is set when the error code in LEC[2:0] is set by hardware on error detection.
- Bit 10 **BOFIE**: Bus-off interrupt enable  
0: ERRI bit is not set when BOFF is set.  
1: ERRI bit is set when BOFF is set.
- Bit 9 **EPVIE**: Error passive interrupt enable  
0: ERRI bit is not set when EPVF is set.  
1: ERRI bit is set when EPVF is set.
- Bit 8 **EWGIE**: Error warning interrupt enable  
0: ERRI bit is not set when EWGF is set.  
1: ERRI bit is set when EWGF is set.
- Bit 7 Reserved, must be kept at reset value.
- Bit 6 **FOVIE1**: FIFO overrun interrupt enable  
0: No interrupt when FOVR is set.  
1: Interrupt generation when FOVR is set.
- Bit 5 **FFIE1**: FIFO full interrupt enable  
0: No interrupt when FULL bit is set.  
1: Interrupt generated when FULL bit is set.
- Bit 4 **FMPIE1**: FIFO message pending interrupt enable  
0: No interrupt generated when state of FMP[1:0] bits are not 00b.  
1: Interrupt generated when state of FMP[1:0] bits are not 00b.
- Bit 3 **FOVIE0**: FIFO overrun interrupt enable  
0: No interrupt when FOVR bit is set.  
1: Interrupt generated when FOVR bit is set.
- Bit 2 **FFIE0**: FIFO full interrupt enable  
0: No interrupt when FULL bit is set.  
1: Interrupt generated when FULL bit is set.
- Bit 1 **FMPIE0**: FIFO message pending interrupt enable  
0: No interrupt generated when state of FMP[1:0] bits are not 00b.  
1: Interrupt generated when state of FMP[1:0] bits are not 00b.
- Bit 0 **TMEIE**: Transmit mailbox empty interrupt enable  
0: No interrupt when RQCPx bit is set.  
1: Interrupt generated when RQCPx bit is set.
- Note: Refer to [Section 46.8: bxCAN interrupts](#).*

**CAN error status register (CAN\_ESR)**

Address offset: 0x18

Reset value: 0x0000 0000

|          |      |      |      |      |      |      |      |          |          |    |    |      |      |      |      |

| r        | r    | r    | r    | r    | r    | r    | r    | r        | r        | r  | r  | r    | r    | r    | r    |
| 15       | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7        | 6        | 5  | 4  | 3    | 2    | 1    | 0    |
| Res.     | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.     | LEC[2:0] |    |    | Res. | BOFF | EPVF | EWGF |
|          |      |      |      |      |      |      |      |          | rw       | rw | rw |      | r    | r    | r    |

Bits 31:24 **REC[7:0]**: Receive error counter

The implementing part of the fault confinement mechanism of the CAN protocol. In case of an error during reception, this counter is incremented by 1 or by 8 depending on the error condition as defined by the CAN standard. After every successful reception the counter is decremented by 1 or reset to 120 if its value was higher than 128. When the counter value exceeds 127, the CAN controller enters the error passive state.

Bits 23:16 **TEC[7:0]**: Least significant byte of the 9-bit transmit error counter

The implementing part of the fault confinement mechanism of the CAN protocol.

Bits 15:7 Reserved, must be kept at reset value.

Bits 6:4 **LEC[2:0]**: Last error code

This field is set by hardware and holds a code which indicates the error condition of the last error detected on the CAN bus. If a message has been transferred (reception or transmission) without error, this field is cleared to 0.

The LEC[2:0] bits can be set to value 0b111 by software. They are updated by hardware to indicate the current communication status.

000: No error

001: Stuff error

010: Form error

011: Acknowledgment error

100: Bit recessive error

101: Bit dominant error

110: CRC error

111: Set by software

Bit 3 Reserved, must be kept at reset value.

Bit 2 **BOFF**: Bus-off flag

This bit is set by hardware when it enters the bus-off state. The bus-off state is entered on TEC overflow, greater than 255, refer to [Section 46.7.6: Error management](#).

Bit 1 **EPVF**: Error passive flag

This bit is set by hardware when the Error passive limit has been reached (Receive Error Counter or Transmit Error Counter > 127).

Bit 0 **EWGF**: Error warning flag

This bit is set by hardware when the warning limit has been reached (Receive Error Counter or Transmit Error Counter ≥ 96).

**CAN bit timing register (CAN\_BTR)**

Address offset: 0x1C

Reset value: 0x0123 0000

This register can only be accessed by the software when the CAN hardware is in initialization mode.

|      |      |      |      |      |      |          |    |      |          |    |    |          |    |    |    |

Bit 31 **SILM**: Silent mode (debug)

0: Normal operation

1: Silent mode

Bit 30 **LBKM**: Loop back mode (debug)

0: Loop back mode disabled

1: Loop back mode enabled

Bits 29:26 Reserved, must be kept at reset value.

Bits 25:24 **SJW[1:0]**: Resynchronization jump width

These bits define the maximum number of time quanta the CAN hardware is allowed to lengthen or shorten a bit to perform the resynchronization.

$$t_{RJW} = t_q \times (SJW[1:0] + 1)$$

Bit 23 Reserved, must be kept at reset value.

Bits 22:20 **TS2[2:0]**: Time segment 2

These bits define the number of time quanta in Time Segment 2.

$$t_{BS2} = t_q \times (TS2[2:0] + 1)$$

Bits 19:16 **TS1[3:0]**: Time segment 1

These bits define the number of time quanta in Time Segment 1

$$t_{BS1} = t_q \times (TS1[3:0] + 1)$$

For more information on bit timing, refer to [Section 46.7.7: Bit timing](#).

Bits 15:10 Reserved, must be kept at reset value.

Bits 9:0 **BRP[9:0]**: Baud rate prescaler

These bits define the length of a time quanta.

$$t_q = (BRP[9:0] + 1) \times t_{PCLK}$$

### 46.9.3 CAN mailbox registers

This chapter describes the registers of the transmit and receives mailboxes. Refer to [Section 46.7.5: Message storage](#) for detailed register mapping.

Transmit and receive mailboxes have the same registers except:

- The FMI field in the CAN\_RDTxR register.
- A receive mailbox is always write protected.
- A transmit mailbox is write-enabled only while empty, corresponding TME bit in the CAN\_TSR register set.

There are three TX mailboxes and two RX mailboxes. Each RX Mailbox allows access to a 3-level depth FIFO, the access being offered only to the oldest received message in the FIFO.

Each mailbox consist of four registers.

**Figure 531. CAN mailbox registers**

#### CAN TX mailbox identifier register (CAN\_TlRxR) (x = 0..2)

Address offsets: 0x180, 0x190, 0x1A0

Reset value: 0xFFFF XXXX (except bit 0, TXRQ = 0)

All TX registers are write protected when the mailbox is pending transmission (TMEx reset).

This register also implements the TX request control (bit 0) - reset value 0.

|                        |    |    |    |    |    |    |    |    |    |    |             |    |     |     |      |
|------------------------|----|----|----|----|----|----|----|----|----|----|-------------|----|-----|-----|------|
| 31                     | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20          | 19 | 18  | 17  | 16   |
| STID[10:0]/EXID[28:18] |    |    |    |    |    |    |    |    |    |    | EXID[17:13] |    |     |     |      |
| rw                     | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw          | rw | rw  | rw  | rw   |
| 15                     | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4           | 3  | 2   | 1   | 0    |
| EXID[12:0]             |    |    |    |    |    |    |    |    |    |    |             |    | IDE | RTR | TXRQ |
| rw                     | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw          | rw | rw  | rw  | rw   |

Bits 31:21 **STID[10:0]/EXID[28:18]**: Standard identifier or extended identifier

The standard identifier or the MSBs of the extended identifier (depending on the IDE bit value).

Bit 20:3 **EXID[17:0]**: Extended identifier

The LSBs of the extended identifier.

Bit 2 **IDE**: Identifier extension

This bit defines the identifier type of message in the mailbox.

0: Standard identifier.

1: Extended identifier.

Bit 1 **RTR**: Remote transmission request

0: Data frame

1: Remote frame

Bit 0 **TXRQ**: Transmit mailbox request

Set by software to request the transmission for the corresponding mailbox.

Cleared by hardware when the mailbox becomes empty.

### CAN mailbox data length control and time stamp register (CAN\_TDTxR) (x = 0..2)

All bits of this register are write protected when the mailbox is not in empty state.

Address offsets: 0x184, 0x194, 0x1A4

Reset value: 0xFFFF XXXX

|            |      |      |      |      |      |      |      |      |      |      |      |          |    |    |    |
|------------|------|------|------|------|------|------|------|------|------|------|------|----------|----|----|----|
| 31         | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19       | 18 | 17 | 16 |
| TIME[15:0] |      |      |      |      |      |      |      |      |      |      |      |          |    |    |    |
| rw         | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw       | rw | rw | rw |
| 15         | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3        | 2  | 1  | 0  |
| Res.       | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | DLC[3:0] |    |    |    |
|            |      |      |      |      |      |      |      |      |      |      |      | rw       | rw | rw | rw |

Bits 31:16 **TIME[15:0]**: Message time stamp

This field contains the 16-bit timer value captured at the SOF transmission.

Bits 15:9 Reserved, must be kept at reset value.

Bit 8 **TGT**: Transmit global time

This bit is active only when the hardware is in the Time Trigger Communication mode, TTCM bit of the CAN\_MCR register is set.

0: Time stamp TIME[15:0] is not sent.

1: Time stamp TIME[15:0] value is sent in the last two data bytes of the 8-byte message: TIME[7:0] in data byte 7 and TIME[15:8] in data byte 6, replacing the data written in CAN\_TDHxR[31:16] register (DATA6[7:0] and DATA7[7:0]). DLC must be programmed as 8 in order these two bytes to be sent over the CAN bus.

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 **DLC[3:0]**: Data length code

This field defines the number of data bytes a data frame contains or a remote frame request.

A message can contain from 0 to 8 data bytes, depending on the value in the DLC field.

### CAN mailbox data low register (CAN\_TDLxR) (x = 0..2)

All bits of this register are write protected when the mailbox is not in empty state.

Address offsets: 0x188, 0x198, 0x1A8

Reset value: 0xFFFF XXXX

|            |    |    |    |    |    |    |    |            |    |    |    |    |    |    |    |
|------------|----|----|----|----|----|----|----|------------|----|----|----|----|----|----|----|
| 31         | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23         | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| DATA3[7:0] |    |    |    |    |    |    |    | DATA2[7:0] |    |    |    |    |    |    |    |
| rw         | rw | rw | rw | rw | rw | rw | rw | rw         | rw | rw | rw | rw | rw | rw | rw |
| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7          | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| DATA1[7:0] |    |    |    |    |    |    |    | DATA0[7:0] |    |    |    |    |    |    |    |
| rw         | rw | rw | rw | rw | rw | rw | rw | rw         | rw | rw | rw | rw | rw | rw | rw |

Bits 31:24 **DATA3[7:0]**: Data byte 3

Data byte 3 of the message.

Bits 23:16 **DATA2[7:0]**: Data byte 2

Data byte 2 of the message.

Bits 15:8 **DATA1[7:0]**: Data byte 1

Data byte 1 of the message.

Bits 7:0 **DATA0[7:0]**: Data byte 0

Data byte 0 of the message.

A message can contain from 0 to 8 data bytes and starts with byte 0.

### CAN mailbox data high register (CAN\_TDHxR) (x = 0..2)

All bits of this register are write protected when the mailbox is not in empty state.

Address offsets: 0x18C, 0x19C, 0x1AC

Reset value: 0xFFFF XXXX

|            |    |    |    |    |    |    |    |            |    |    |    |    |    |    |    |
|------------|----|----|----|----|----|----|----|------------|----|----|----|----|----|----|----|
| 31         | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23         | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| DATA7[7:0] |    |    |    |    |    |    |    | DATA6[7:0] |    |    |    |    |    |    |    |
| rw         | rw | rw | rw | rw | rw | rw | rw | rw         | rw | rw | rw | rw | rw | rw | rw |
| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7          | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| DATA5[7:0] |    |    |    |    |    |    |    | DATA4[7:0] |    |    |    |    |    |    |    |
| rw         | rw | rw | rw | rw | rw | rw | rw | rw         | rw | rw | rw | rw | rw | rw | rw |

Bits 31:24 **DATA7[7:0]**: Data byte 7

Data byte 7 of the message.

*Note: If TGT of this message and TTCM are active, DATA7 and DATA6 are replaced by the TIME stamp value.*

Bits 23:16 **DATA6[7:0]**: Data byte 6

Data byte 6 of the message.

Bits 15:8 **DATA5[7:0]**: Data byte 5

Data byte 5 of the message.

Bits 7:0 **DATA4[7:0]**: Data byte 4

Data byte 4 of the message.

**CAN receive FIFO mailbox identifier register (CAN\_RlRxR) (x = 0..1)**

Address offsets: 0x1B0, 0x1C0

Reset value: 0xFFFF XXXX

All RX registers are write protected.

|                        |    |    |    |    |    |    |    |    |    |    |             |     |     |     |    |
|------------------------|----|----|----|----|----|----|----|----|----|----|-------------|-----|-----|-----|----|
| 31                     | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20          | 19  | 18  | 17  | 16 |
| STID[10:0]/EXID[28:18] |    |    |    |    |    |    |    |    |    |    | EXID[17:13] |     |     |     |    |
| r                      | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r           | r   | r   | r   | r  |
| 15                     | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4           | 3   | 2   | 1   | 0  |
| EXID[12:0]             |    |    |    |    |    |    |    |    |    |    |             | IDE | RTR | Res |    |
| r                      | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r           | r   | r   |     |    |

Bits 31:21 **STID[10:0]/EXID[28:18]**: Standard identifier or extended identifier

The standard identifier or the MSBs of the extended identifier (depending on the IDE bit value).

Bits 20:3 **EXID[17:0]**: Extended identifier

The LSBs of the extended identifier.

Bit 2 **IDE**: Identifier extension

This bit defines the identifier type of message in the mailbox.

0: Standard identifier.

1: Extended identifier.

Bit 1 **RTR**: Remote transmission request

0: Data frame

1: Remote frame

Bit 0 Reserved, must be kept at reset value.

**CAN receive FIFO mailbox data length control and time stamp register (CAN\_RDTxR) (x = 0..1)**

Address offsets: 0x1B4, 0x1C4

Reset value: 0xFFFF XXXX

All RX registers are write protected.

|            |    |    |    |    |    |    |    |      |      |      |      |          |    |    |    |
|------------|----|----|----|----|----|----|----|------|------|------|------|----------|----|----|----|

| FMI[7:0]   |    |    |    |    |    |    |    | Res. | Res. | Res. | Res. | DLC[3:0] |    |    |    |
| r          | r  | r  | r  | r  | r  | r  | r  |      |      |      |      | r        | r  | r  | r  |

Bits 31:16 **TIME[15:0]**: Message time stamp

This field contains the 16-bit timer value captured at the SOF detection.

Bits 15:8 **FMI[7:0]**: Filter match index

This register contains the index of the filter the message stored in the mailbox passed through. For more details on identifier filtering, refer to [Section 46.7.4: Identifier filtering](#).

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 **DLC[3:0]**: Data length code

This field defines the number of data bytes a data frame contains (0 to 8). It is 0 in the case of a remote frame request.

### CAN receive FIFO mailbox data low register (CAN\_RDLxR) (x = 0..1)

All bits of this register are write protected when the mailbox is not in empty state.

Address offsets: 0x1B8, 0x1C8

Reset value: 0xFFFF XXXX

All RX registers are write protected.

|            |    |    |    |    |    |    |    |            |    |    |    |    |    |    |    |
|------------|----|----|----|----|----|----|----|------------|----|----|----|----|----|----|----|
| 31         | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23         | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| DATA3[7:0] |    |    |    |    |    |    |    | DATA2[7:0] |    |    |    |    |    |    |    |
| r          | r  | r  | r  | r  | r  | r  | r  | r          | r  | r  | r  | r  | r  | r  | r  |
| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7          | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| DATA1[7:0] |    |    |    |    |    |    |    | DATA0[7:0] |    |    |    |    |    |    |    |
| r          | r  | r  | r  | r  | r  | r  | r  | r          | r  | r  | r  | r  | r  | r  | r  |

Bits 31:24 **DATA3[7:0]**: Data byte 3

Data byte 3 of the message.

Bits 23:16 **DATA2[7:0]**: Data byte 2

Data byte 2 of the message.

Bits 15:8 **DATA1[7:0]**: Data byte 1

Data byte 2 of the message.

Bits 7:0 **DATA0[7:0]**: Data byte 0

Data byte 0 of the message.

A message can contain from 0 to 8 data bytes and starts with byte 0.

### CAN receive FIFO mailbox data high register (CAN\_RDHxR) (x = 0..1)

Address offsets: 0x1BC, 0x1CC

Reset value: 0xFFFF XXXX

All RX registers are write protected.

|            |    |    |    |    |    |    |    |            |    |    |    |    |    |    |    |
|------------|----|----|----|----|----|----|----|------------|----|----|----|----|----|----|----|
| 31         | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23         | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| DATA7[7:0] |    |    |    |    |    |    |    | DATA6[7:0] |    |    |    |    |    |    |    |
| r          | r  | r  | r  | r  | r  | r  | r  | r          | r  | r  | r  | r  | r  | r  | r  |
| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7          | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| DATA5[7:0] |    |    |    |    |    |    |    | DATA4[7:0] |    |    |    |    |    |    |    |
| r          | r  | r  | r  | r  | r  | r  | r  | r          | r  | r  | r  | r  | r  | r  | r  |

Bits 31:24 **DATA7[7:0]**: Data byte 7  
Data byte 3 of the message.

Bits 23:16 **DATA6[7:0]**: Data byte 6  
Data byte 2 of the message.

Bits 15:8 **DATA5[7:0]**: Data byte 5  
Data byte 1 of the message.

Bits 7:0 **DATA4[7:0]**: Data byte 4  
Data byte 0 of the message.

## 46.9.4 CAN filter registers

### CAN filter master register (CAN\_FMR)

Address offset: 0x200

Reset value: 0x2A1C 0E01

All bits of this register are set and cleared by software.

|      |      |            |      |      |      |      |      |      |      |      |      |      |      |      |       |

Bits 31:14 Reserved, must be kept at reset value.

Bits 13:8 **CANSB[5:0]**: CAN start bank

These bits are set and cleared by software. When both CAN are used, they define the start bank of each CAN interface:

000001 = 1 filter assigned to CAN1 and 27 assigned to CAN2

011011 = 27 filters assigned to CAN1 and 1 filter assigned to CAN2

- to assign all filters to one CAN set CANSB value to zero and deactivate the non used CAN
- to use CAN1 only: stop the clock on CAN2 and/or set the CAN\_MCR.INRQ on CAN2
- to use CAN2 only: set the CAN\_MCR.INRQ on CAN1 or deactivate the interrupt register CAN\_IER on CAN1

*Note: Bits [13:8] are available only for dual CAN peripheral configuration and are reserved for single CAN peripheral configuration.*

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 **FINIT**: Filter initialization mode

Initialization mode for filter banks

0: Active filters mode.

1: Initialization mode for the filters.

### CAN filter mode register (CAN\_FM1R)

Address offset: 0x204

Reset value: 0x0000 0000

This register can be written only when the filter initialization mode is set (FINIT=1) in the CAN\_FMR register.

**Note:** Refer to [Figure 524: Filter bank scale configuration - Register organization](#).

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:0 **FBMx**: Filter mode

Mode of the registers of Filter x.

0: Two 32-bit registers of filter bank x are in Identifier Mask mode.

1: Two 32-bit registers of filter bank x are in Identifier List mode.

**Note:** Bits 27:14 are available for dual CAN configuration and are reserved for single CAN configuration.

### CAN filter scale register (CAN\_FS1R)

Address offset: 0x20C

Reset value: 0x0000 0000

This register can be written only when the filter initialization mode is set (FINIT=1) in the CAN\_FMR register.

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:0 **FSCx**: Filter scale configuration

These bits define the scale configuration of Filters 27-0.

0: Dual 16-bit scale configuration

1: Single 32-bit scale configuration

*Note: Bits 27:14 are available for dual CAN configuration and are reserved for single CAN configuration.*

*Note: Refer to [Figure 524: Filter bank scale configuration - Register organization](#).*

### CAN filter FIFO assignment register (CAN\_FFA1R)

Address offset: 0x214

Reset value: 0x0000 0000

This register can be written only when the filter initialization mode is set (FINIT=1) in the CAN\_FMR register.

|       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:0 **FFAx**: Filter FIFO assignment for filter x

The message passing through this filter is stored in the specified FIFO.

0: Filter assigned to FIFO 0

1: Filter assigned to FIFO 1

*Note: Bits 27:14 are available for dual CAN configuration and are reserved for single CAN configuration.*

### CAN filter activation register (CAN\_FA1R)

Address offset: 0x21C

Reset value: 0x0000 0000

|         |         |         |         |         |         |         |         |         |         |         |         |         |         |         |         |

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:0 **FACTx**: Filter active

The software sets this bit to activate Filter x. To modify the Filter x registers (CAN\_FxR[0:7]), the FACTx bit must be cleared or the FINIT bit of the CAN\_FMR register must be set.

0: Filter x is not active

1: Filter x is active

*Note: Bits 27:14 are available for dual CAN configuration and are reserved for single CAN configuration.*

**Filter bank i register x (CAN\_FiRx) (i = 0..27, x = 1, 2)**

Address offsets: 0x240 to 0x31C

Reset value: 0xFFFF XXXX

Depending on CAN peripheral configuration there *are* 28 *filter banks*, in dual CAN or 14 filter banks in single CAN configuration. Each filter bank i (i= 0 to 27 in dual CAN configuration and i= 0 to 13 in single CAN configuration) is composed of two 32-bit registers, CAN\_FiR[2:1].

This register can only be modified when the FACTx bit of the CAN\_FAxR register is cleared or when the FINIT bit of the CAN\_FMR register is set.

|      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|

In all configurations:

Bits 31:0 **FB[31:0]**: Filter bits

**Identifier**

Each bit of the register specifies the level of the corresponding bit of the expected identifier.

0: Dominant bit is expected

1: Recessive bit is expected

**Mask**

Each bit of the register specifies whether the bit of the associated identifier register must match with the corresponding bit of the expected identifier or not.

0: Do not care, the bit is not used for the comparison

1: Must match, the bit of the incoming identifier must have the same level has specified in the corresponding identifier register of the filter.

**Note:** *Depending on the scale and mode configuration of the filter, the function of each register can differ. For the filter mapping, functions description and mask registers association, refer to [Section 46.7.4: Identifier filtering](#).*

A Mask/Identifier register in **mask mode** has the same bit mapping as in **identifier list** mode.

*For the register mapping/addresses of the filter banks refer to [Table 316](#).*

## 46.9.5 bxCAN register map

Refer to [Section 2.2 on page 75](#) for the register boundary addresses. The registers from offset 0x200 to 0x31C are present only in CAN1.

**Table 316. bxCAN register map and reset values**

| Offset      | Register    | 31                     | 30   | 29  | 28  | 27       | 26  | 25       | 24        | 23       | 22       | 21  | 20  | 19         | 18    | 17    | 16    | 15    | 14    | 13  | 12  | 11  | 10    | 9        | 8     | 7     | 6     | 5   | 4        | 3     | 2      | 1      | 0         |        |       |      |  |  |

Refer to [Section 2.2 on page 75](#) for the register boundary addresses.

## 47 USB on-the-go full-speed (OTG\_FS)

This section applies to STM32L4x5/L4x6 devices only.

### 47.1 Introduction

Portions Copyright (c) Synopsys, Inc. All rights reserved. Used with permission.

This section presents the architecture and the programming model of the OTG\_FS controller.

The following acronyms are used throughout the section:

|      |                                                |
|------|------------------------------------------------|
| FS   | Full-speed                                     |
| LS   | Low-speed                                      |
| MAC  | Media access controller                        |
| OTG  | On-the-go                                      |
| PFC  | Packet FIFO controller                         |
| PHY  | Physical layer                                 |
| USB  | Universal serial bus                           |
| UTMI | USB 2.0 Transceiver Macrocell interface (UTMI) |
| ADP  | Attach detection protocol                      |
| LPM  | Link power management                          |
| BCD  | Battery charging detector                      |
| HNP  | Host negotiation protocol                      |
| SRP  | Session request protocol                       |

References are made to the following documents:

- USB On-The-Go Supplement, Revision 2.0
- Universal Serial Bus Revision 2.0 Specification
- USB 2.0 Link Power Management Addendum Engineering Change Notice to the USB 2.0 specification, July 16, 2007
- Errata for USB 2.0 ECN: Link Power Management (LPM) - 7/2007
- Battery Charging Specification, Revision 1.2

The USB OTG is a dual-role device (DRD) controller that supports both device and host functions and is fully compliant with the *On-The-Go Supplement to the USB 2.0 Specification*. It can also be configured as a host-only or device-only controller, fully compliant with the *USB 2.0 Specification*. OTG\_FS supports the speeds defined in the [Table 317: OTG\\_FS speeds supported](#) below. The USB OTG supports both HNP and SRP. The only external device required is a charge pump for  $V_{BUS}$  in OTG mode.

Table 317. OTG\_FS speeds supported

| -           | HS (480 Mb/s) | FS (12 Mb/s) | LS (1.5 Mb/s) |
|-------------|---------------|--------------|---------------|
| Host mode   | -             | X            | X             |
| Device mode | -             | X            | -             |

## 47.2 OTG\_FS main features

The main features can be divided into three categories: general, host-mode and device-mode features.

### 47.2.1 General features

The OTG\_FS interface general features are the following:

- It is USB-IF certified to the Universal Serial Bus Specification Rev 2.0
- OTG\_FS supports the following PHY interface:
  - An on-chip full-speed PHY
- It includes full support (PHY) for the optional On-The-Go (OTG) protocol detailed in the On-The-Go Supplement Rev 2.0 specification
  - Integrated support for A-B device identification (ID line)
  - Integrated support for host Negotiation protocol (HNP) and session request protocol (SRP)
  - It allows host to turn  $V_{BUS}$  off to conserve battery power in OTG applications
  - It supports OTG monitoring of  $V_{BUS}$  levels with internal comparators
  - It supports dynamic host-peripheral switch of role
- It is software-configurable to operate as:
  - SRP capable USB FS Peripheral (B-device)
  - SRP capable USB FS/LS host (A-device)
  - USB On-The-Go Full-Speed Dual Role device
- It supports FS SOF and LS Keep-alives with
  - SOF pulse PAD connectivity
  - SOF pulse internal connection to timer (TIMx)
  - Configurable framing period
  - Configurable end of frame interrupt
- It includes power saving features such as system stop during USB suspend, switch-off of clock domains internal to the digital core, PHY and DFIFO power management.
- It features a dedicated RAM of 1.25 Kbytes with advanced FIFO control:
  - Configurable partitioning of RAM space into different FIFOs for flexible and efficient use of RAM
  - Each FIFO can hold multiple packets
  - Dynamic memory allocation
  - Configurable FIFO sizes that are not powers of 2 to allow the use of contiguous memory locations
- It guarantees max USB bandwidth for up to one frame (1 ms) without system intervention.
- It supports charging port detection as described in Battery Charging Specification Revision 1.2 on the FS PHY transceiver only.
- It supports attach detection protocol (ADP).

### 47.2.2 Host-mode features

The OTG\_FS interface main features and requirements in host-mode are the following:

- External charge pump for  $V_{BUS}$  voltage generation.
- Up to 12 host channels (pipes): each channel is dynamically reconfigurable to allocate any type of USB transfer.
- Built-in hardware scheduler holding:
  - Up to 12 interrupt plus isochronous transfer requests in the periodic hardware queue
  - Up to 12 control plus bulk transfer requests in the non-periodic hardware queue
- Management of a shared Rx FIFO, a periodic Tx FIFO and a nonperiodic Tx FIFO for efficient usage of the USB data RAM.

### 47.2.3 Peripheral-mode features

The OTG\_FS interface main features in peripheral-mode are the following:

- 1 bidirectional control endpoint0
- 5 IN endpoints (EPs) configurable to support bulk, interrupt or isochronous transfers
- 5 OUT endpoints configurable to support bulk, interrupt or isochronous transfers
- Management of a shared Rx FIFO and a Tx-OUT FIFO for efficient usage of the USB data RAM
- Management of up to 6 dedicated Tx-IN FIFOs (one for each active IN EP) to put less load on the application
- Support for the soft disconnect feature.

## 47.3 OTG\_FS implementation

Table 318. OTG\_FS implementation<sup>(1)</sup>

| USB features                                   | OTG_FS for<br>STM32L47x/L48x | OTG_FS for<br>STM32L49x/L4Ax |
|------------------------------------------------|------------------------------|------------------------------|
| Device bidirectional endpoints (including EP0) | 6                            | 6                            |
| Host mode channels                             | 12                           | 12                           |
| Size of dedicated SRAM                         | 1.2 KB                       | 1.2 KB                       |
| USB 2.0 link power management (LPM) support    | X                            | X                            |
| OTG revision supported                         | 2.0                          | 2.0                          |
| Attach detection protocol (ADP) support        | X                            | X                            |
| Battery charging detection (BCD) support       | X                            | X                            |
| PSRST / ERRATIM / STSPHST / CURMOD bits        | -                            | X                            |

1. "X" = supported, "-" not supported

| usb_wkup    | Digital output | USB OTG wake-up event output                         |
| usb_gbl_it  | Digital output | USB OTG global interrupt                             |

### 47.4.3 OTG\_FS core

The USB OTG\_FS receives the 48 MHz clock from the reset and clock controller (RCC). This clock is used for driving the 48 MHz domain at full-speed (12 Mbit/s) and must be enabled prior to configuring the OTG core.

The CPU reads and writes from/to the OTG core registers through the AHB peripheral bus. It is informed of USB events through the single USB OTG interrupt line described in [Section 47.13: OTG\\_FS interrupts](#).

The CPU submits data over the USB by writing 32-bit words to dedicated OTG locations (push registers). The data are then automatically stored into Tx-data FIFOs configured within the USB data RAM. There is one Tx FIFO push register for each in-endpoint (peripheral mode) or out-channel (host mode).

The CPU receives the data from the USB by reading 32-bit words from dedicated OTG addresses (pop registers). The data are then automatically retrieved from a shared Rx FIFO configured within the 1.25-Kbyte USB data RAM. There is one Rx FIFO pop register for each out-endpoint or in-channel.

The USB protocol layer is driven by the serial interface engine (SIE) and serialized over the USB by the transceiver module within the on-chip physical layer (PHY).

**Caution:** To guarantee a correct operation for the USB OTG FS peripheral, the AHB frequency must be higher than 14.2 MHz.

### 47.4.4 Embedded full-speed OTG PHY connected to OTG\_FS

The embedded full-speed OTG PHY is controlled by the OTG FS core and conveys USB control & data signals through the full-speed subset of the UTMI+ Bus (UTMIFS). It provides the physical support to USB connectivity.

The full-speed OTG PHY includes the following components:

- FS/LS transceiver module used by both host and device. It directly drives transmission and reception on the single-ended USB lines.
- DP/DM integrated pull-up and pull-down resistors controlled by the OTG\_FS core depending on the current role of the device. As a peripheral, it enables the DP pull-up resistor to signal full-speed peripheral connections as soon as  $V_{BUS}$  is sensed to be at a valid level (B-session valid). In host mode, pull-down resistors are enabled on both DP/DM. Pull-up and pull-down resistors are dynamically switched when the role of the device is changed via the host negotiation protocol (HNP).
- Pull-up/pull-down resistor ECN circuit. The DP pull-up consists of two resistors controlled separately from the OTG\_FS as per the resistor Engineering Change Notice applied to USB Rev2.0. The dynamic trimming of the DP pull-up strength allows for better noise rejection and Tx/Rx signal quality.

### 47.4.5 OTG detections

Additionally the OTG\_FS uses the following functions:

- integrated ID pull-up resistor used to sample the ID line for A/B device identification.
- $V_{BUS}$  sensing comparators with hysteresis used to detect  $V_{BUS}$  valid, A-B session valid and session-end voltage thresholds. They are used to drive the session request protocol (SRP), detect valid startup and end-of-session conditions, and constantly monitor the  $V_{BUS}$  supply during USB operations.

## 47.5 OTG\_FS dual role device (DRD)

Figure 533. OTG\_FS A-B device connection

1. External voltage regulator only needed when building a VBUS powered device.
2. STMP2141STR needed only if the application has to support a VBUS powered device. A basic power switch can be used if 5 V are available on the application board.

### 47.5.1 ID line detection

The host or peripheral (the default) role is assumed depending on the ID input pin. The ID line status is determined on plugging in the USB cable, depending on whether a MicroA or MicroB plug is connected to the micro-AB receptacle.

- If the B-side of the USB cable is connected with a floating ID wire, the integrated pull-up resistor detects a high ID level and the default peripheral role is confirmed. In this configuration the OTG\_FS complies with the standard FSM described in section 4.2.4: ID pin of the On-the-Go specification Rev2.0, supplement to the USB2.0.
- If the A-side of the USB cable is connected with a grounded ID, the OTG\_FS issues an ID line status change interrupt (CIDSCHG bit in OTG\_GINTSTS) for host software initialization, and automatically switches to the host role. In this configuration the OTG\_FS complies with the standard FSM described by section 4.2.4: ID pin of the On-the-Go specification Rev2.0, supplement to the USB2.0.

### 47.5.2 HNP dual role device

The HNP capable bit in the Global USB configuration register (HNPCAP bit in OTG\_GUSBCFG) enables the OTG\_FS core to dynamically change its role from A-host to A-peripheral and vice-versa, or from B-Peripheral to B-host and vice-versa according to the host negotiation protocol (HNP). The current device status can be read by the combined values of the connector ID status bit in the Global OTG control and status register (CIDSTS bit in OTG\_GOTGCTL) and the current mode of operation bit in the global interrupt and status register (CMOD bit in OTG\_GINTSTS).

The HNP program model is described in detail in [Section 47.16: OTG\\_FS programming model](#).

### 47.5.3 SRP dual role device

The SRP capable bit in the global USB configuration register (SRPCAP bit in OTG\_GUSBCFG) enables the OTG\_FS core to switch off the generation of  $V_{BUS}$  for the A-device to save power. Note that the A-device is always in charge of driving  $V_{BUS}$  regardless of the host or peripheral role of the OTG\_FS.

The SRP A/B-device program model is described in detail in [Section 47.16: OTG\\_FS programming model](#).

## 47.6 OTG\_FS as a USB peripheral

This section gives the functional description of the OTG\_FS in the USB peripheral mode. The OTG\_FS works as an USB peripheral in the following circumstances:

- OTG B-Peripheral
  - OTG B-device default state if B-side of USB cable is plugged in
- OTG A-Peripheral
  - OTG A-device state after the HNP switches the OTG\_FS to its peripheral role
- B-device
  - If the ID line is present, functional and connected to the B-side of the USB cable, and the HNP-capable bit in the Global USB Configuration register (HNPCAP bit in OTG\_GUSBCFG) is cleared.
- Peripheral only (see [Figure 534: OTG\\_FS peripheral-only connection](#))
  - The force device mode bit (FDMOD) in the [Section 47.15.4: OTG USB configuration register \(OTG\\_GUSBCFG\)](#) is set to 1, forcing the OTG\_FS core to work as an USB peripheral-only. In this case, the ID line is ignored even if it is present on the USB connector.

**Note:** *To build a bus-powered device implementation in case of the B-device or peripheral-only configuration, an external regulator has to be added, that generates the necessary power-supply from  $V_{BUS}$ .*

Figure 534. OTG\_FS peripheral-only connection

1. Use a regulator to build a bus-powered device.

### 47.6.1 SRP-capable peripheral

The SRP capable bit in the Global USB configuration register (SRPCAP bit in OTG\_GUSBCFG) enables the OTG\_FS to support the session request protocol (SRP). In this way, it allows the remote A-device to save power by switching off  $V_{BUS}$  while the USB session is suspended.

The SRP peripheral mode program model is described in detail in the [B-device session request protocol](#) section.

### 47.6.2 Peripheral states

#### Powered state

The  $V_{BUS}$  input detects the B-session valid voltage by which the USB peripheral is allowed to enter the powered state (see USB2.0 section 9.1). The OTG\_FS then automatically connects the DP pull-up resistor to signal full-speed device connection to the host and generates the session request interrupt (SRQINT bit in OTG\_GINTSTS) to notify the powered state.

The  $V_{BUS}$  input also ensures that valid  $V_{BUS}$  levels are supplied by the host during USB operations. If a drop in  $V_{BUS}$  below B-session valid happens to be detected (for instance because of a power disturbance or if the host port has been switched off), the OTG\_FS automatically disconnects and the session end detected (SEDET bit in OTG\_GOTGINT) interrupt is generated to notify that the OTG\_FS has exited the powered state.

In the powered state, the OTG\_FS expects to receive some reset signaling from the host. No other USB operation is possible. When a reset signaling is received the reset detected interrupt (USBRST in OTG\_GINTSTS) is generated. When the reset signaling is complete, the enumeration done interrupt (ENUMDNE bit in OTG\_GINTSTS) is generated and the OTG\_FS enters the Default state.

### Soft disconnect

The powered state can be exited by software with the soft disconnect feature. The DP pull-up resistor is removed by setting the soft disconnect bit in the device control register (SDIS bit in OTG\_DCTL), causing a device disconnect detection interrupt on the host side even though the USB cable was not really removed from the host port.

### Default state

In the Default state the OTG\_FS expects to receive a SET\_ADDRESS command from the host. No other USB operation is possible. When a valid SET\_ADDRESS command is decoded on the USB, the application writes the corresponding number into the device address field in the device configuration register (DAD bit in OTG\_DCFG). The OTG\_FS then enters the address state and is ready to answer host transactions at the configured USB address.

### Suspended state

The OTG\_FS peripheral constantly monitors the USB activity. After counting 3 ms of USB idleness, the early suspend interrupt (ESUSP bit in OTG\_GINTSTS) is issued, and confirmed 3 ms later, if appropriate, by the suspend interrupt (USBSUSP bit in OTG\_GINTSTS). The device suspend bit is then automatically set in the device status register (SUSPSTS bit in OTG\_DSTS) and the OTG\_FS enters the suspended state.

The suspended state may optionally be exited by the device itself. In this case the application sets the remote wake-up signaling bit in the device control register (RWUSIG bit in OTG\_DCTL) and clears it after 1 to 15 ms.

When a resume signaling is detected from the host, the resume interrupt (WKUPINT bit in OTG\_GINTSTS) is generated and the device suspend bit is automatically cleared.

## 47.6.3 Peripheral endpoints

The OTG\_FS core instantiates the following USB endpoints:

- Control endpoint 0:
  - Bidirectional and handles control messages only
  - Separate set of registers to handle in and out transactions
  - Proper control (OTG\_DIEPCTL0/OTG\_DOEPCTL0), transfer configuration (OTG\_DIEPTSIZ0/OTG\_DOEPSIZ0), and status-interrupt (OTG\_DIEPINT0/OTG\_DOEPINT0) registers. The available set of bits inside the control and transfer size registers slightly differs from that of other endpoints
- 5 IN endpoints
  - Each of them can be configured to support the isochronous, bulk or interrupt transfer type
  - Each of them has proper control (OTG\_DIEPCTLx), transfer configuration (OTG\_DIEPTSIZx), and status-interrupt (OTG\_DIEPINTx) registers
  - The device IN endpoints common interrupt mask register (OTG\_DIEPMSK) is available to enable/disable a single kind of endpoint interrupt source on all of the IN endpoints (EP0 included)
  - Support for incomplete isochronous IN transfer interrupt (IISOIXFR bit in OTG\_GINTSTS), asserted when there is at least one isochronous IN endpoint on

which the transfer is not completed in the current frame. This interrupt is asserted along with the end of periodic frame interrupt (OTG\_GINTSTS/EOPF).

- 5 OUT endpoints
  - Each of them can be configured to support the isochronous, bulk or interrupt transfer type
  - Each of them has a proper control (OTG\_DOEPCTLx), transfer configuration (OTG\_DOEPTSIZx) and status-interrupt (OTG\_DOEPINTx) register
  - Device OUT endpoints common interrupt mask register (OTG\_DOEPMSK) is available to enable/disable a single kind of endpoint interrupt source on all of the OUT endpoints (EP0 included)
  - Support for incomplete isochronous OUT transfer interrupt (INCOMPISOOUT bit in OTG\_GINTSTS), asserted when there is at least one isochronous OUT endpoint on which the transfer is not completed in the current frame. This interrupt is asserted along with the end of periodic frame interrupt (OTG\_GINTSTS/EOPF).

### Endpoint control

- The following endpoint controls are available to the application through the device endpoint-x IN/OUT control register (OTG\_DIEPCTLx/OTG\_DOEPCTLx):
  - Endpoint enable/disable
  - Endpoint activate in current configuration
  - Program USB transfer type (isochronous, bulk, interrupt)
  - Program supported packet size
  - Program Tx FIFO number associated with the IN endpoint
  - Program the expected or transmitted data0/data1 PID (bulk/interrupt only)
  - Program the even/odd frame during which the transaction is received or transmitted (isochronous only)
  - Optionally program the NAK bit to always negative-acknowledge the host regardless of the FIFO status
  - Optionally program the STALL bit to always stall host tokens to that endpoint
  - Optionally program the SNOOP mode for OUT endpoint not to check the CRC field of received data

### Endpoint transfer

The device endpoint-x transfer size registers (OTG\_DIEPTSIZx/OTG\_DOEPTSIZx) allow the application to program the transfer size parameters and read the transfer status. Programming must be done before setting the endpoint enable bit in the endpoint control register. Once the endpoint is enabled, these fields are read-only as the OTG\_FS core updates them with the current transfer status.

The following transfer parameters can be programmed:

- Transfer size in bytes
- Number of packets that constitute the overall transfer size

### Endpoint status/interrupt

The device endpoint-x interrupt registers (OTG\_DIEPINTx/OTG\_DOEPINTx) indicate the status of an endpoint with respect to USB- and AHB-related events. The application must read these registers when the OUT endpoint interrupt bit or the IN endpoint interrupt bit in

the core interrupt register (OEPINT bit in OTG\_GINTSTS or IEPINT bit in OTG\_GINTSTS, respectively) is set. Before the application can read these registers, it must first read the device all endpoints interrupt (OTG\_DAINTE) register to get the exact endpoint number for the device endpoint-x interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the OTG\_DAINTE and OTG\_GINTSTS registers

The peripheral core provides the following status checks and interrupt generation:

- Transfer completed interrupt, indicating that data transfer was completed on both the application (AHB) and USB sides
- Setup stage has been done (control-out only)
- Associated transmit FIFO is half or completely empty (in endpoints)
- NAK acknowledge has been transmitted to the host (isochronous-in only)
- IN token received when Tx FIFO was empty (bulk-in/interrupt-in only)
- Out token received when endpoint was not yet enabled
- Babble error condition has been detected
- Endpoint disable by application is effective
- Endpoint NAK by application is effective (isochronous-in only)
- More than 3 back-to-back setup packets were received (control-out only)
- Timeout condition detected (control-in only)
- Isochronous out packet has been dropped, without generating an interrupt

## 47.7 OTG\_FS as a USB host

This section gives the functional description of the OTG\_FS in the USB host mode. The OTG\_FS works as a USB host in the following circumstances:

- OTG A-host
  - OTG A-device default state when the A-side of the USB cable is plugged in
- OTG B-host
  - OTG B-device after HNP switching to the host role
- A-device
  - If the ID line is present, functional and connected to the A-side of the USB cable, and the HNP-capable bit is cleared in the Global USB Configuration register (HNPCAP bit in OTG\_GUSBCFG). Integrated pull-down resistors are automatically set on the DP/DM lines.
- Host only
  - The force host mode bit (FHMOD) in the [OTG USB configuration register \(OTG\\_GUSBCFG\)](#) forces the OTG\_FS core to work as a USB host-only. In this case, the ID line is ignored even if present on the USB connector. Integrated pull-down resistors are automatically set on the DP/DM lines.

*Note:* On-chip 5 V  $V_{BUS}$  generation is not supported. For this reason, a charge pump or, if 5 V are available on the application board, a basic power switch must be added externally to drive the 5 V  $V_{BUS}$  line. The external charge pump can be driven by any GPIO output. This is required for the OTG A-host, A-device and host-only configurations.

Figure 535. OTG\_FS host-only connection

MSv36915V2

1.  $V_{DD}$  range is between 2 V and 3.6 V.

### 47.7.1 SRP-capable host

SRP support is available through the SRP capable bit in the global USB configuration register (SRPCAP bit in OTG\_GUSBCFG). With the SRP feature enabled, the host can save power by switching off the  $V_{BUS}$  power while the USB session is suspended.

The SRP host mode program model is described in detail in the [A-device session request protocol](#) section.

### 47.7.2 USB host states

#### Host port power

On-chip 5 V  $V_{BUS}$  generation is not supported. For this reason, a charge pump or, if 5 V are available on the application board, a basic power pump, must be added externally to drive the 5 V  $V_{BUS}$  line. The external charge pump can be driven by any GPIO output or via an I<sup>2</sup>C interface connected to an external PMIC (power management IC). When the application decides to power on  $V_{BUS}$ , it must also set the port power bit in the host port control and status register (PPWR bit in OTG\_HPRT).

#### $V_{BUS}$ valid

When HNP or SRP is enabled the VBUS sensing pin must be connected to  $V_{BUS}$ . The  $V_{BUS}$  input ensures that valid  $V_{BUS}$  levels are supplied by the charge pump during USB operations. Any unforeseen  $V_{BUS}$  voltage drop below the  $V_{BUS}$  valid threshold (4.4 V) leads to an OTG interrupt triggered by the session end detected bit (SEDET bit in OTG\_GOTGINT). The application is then required to remove the  $V_{BUS}$  power and clear the port power bit.

When HNP and SRP are both disabled, the VBUS sensing pin does not need to be connected to  $V_{BUS}$ .

The charge pump overcurrent flag can also be used to prevent electrical damage. Connect the overcurrent flag output from the charge pump to any GPIO input and configure it to generate a port interrupt on the active level. The overcurrent ISR must promptly disable the  $V_{BUS}$  generation and clear the port power bit.

### Host detection of a peripheral connection

If SRP or HNP are enabled, even if USB peripherals or B-devices can be attached at any time, the OTG\_FS does not detect any bus connection until  $V_{BUS}$  is no longer sensed at a valid level (5 V). When  $V_{BUS}$  is at a valid level and a remote B-device is attached, the OTG\_FS core issues a host port interrupt triggered by the device connected bit in the host port control and status register (PCDET bit in OTG\_HPRT).

When HNP and SRP are both disabled, USB peripherals or B-device are detected as soon as they are connected. The OTG\_FS core issues a host port interrupt triggered by the device connected bit in the host port control and status (PCDET bit in OTG\_HPRT).

### Host detection of peripheral a disconnection

The peripheral disconnection event triggers the disconnect detected interrupt (DISCINT bit in OTG\_GINTSTS).

### Host enumeration

After detecting a peripheral connection the host must start the enumeration process by sending USB reset and configuration commands to the new peripheral.

Before starting to drive a USB reset, the application waits for the OTG interrupt triggered by the debounce done bit (DBCDNE bit in OTG\_GOTGINT), which indicates that the bus is stable again after the electrical debounce caused by the attachment of a pull-up resistor on DP (FS) or DM (LS).

The application drives a USB reset signaling (single-ended zero) over the USB by keeping the port reset bit set in the host port control and status register (PRST bit in OTG\_HPRT) for a minimum of 10 ms and a maximum of 20 ms. The application takes care of the timing count and then of clearing the port reset bit.

Once the USB reset sequence has completed, the host port interrupt is triggered by the port enable/disable change bit (PENCHNG bit in OTG\_HPRT). This informs the application that the speed of the enumerated peripheral can be read from the port speed field in the host port control and status register (PSPD bit in OTG\_HPRT) and that the host is starting to drive SOFs (FS) or Keep alives (LS). The host is now ready to complete the peripheral enumeration by sending peripheral configuration commands.

### Host suspend

The application decides to suspend the USB activity by setting the port suspend bit in the host port control and status register (PSUSP bit in OTG\_HPRT). The OTG\_FS core stops sending SOFs and enters the suspended state.

The suspended state can be optionally exited on the remote device's initiative (remote wake-up). In this case the remote wake-up interrupt (WKUPINT bit in OTG\_GINTSTS) is generated upon detection of a remote wake-up signaling, the port resume bit in the host port control and status register (PRES bit in OTG\_HPRT) self-sets, and resume signaling is automatically driven over the USB. The application must time the resume window and then clear the port resume bit to exit the suspended state and restart the SOF.

If the suspended state is exited on the host initiative, the application must set the port resume bit to start resume signaling on the host port, time the resume window and finally clear the port resume bit.

### 47.7.3 Host channels

The OTG\_FS core instantiates 12 host channels. Each host channel supports an USB host transfer (USB pipe). The host is not able to support more than 12 transfer requests at the same time. If more than 12 transfer requests are pending from the application, the host controller driver (HCD) must re-allocate channels when they become available from previous duty, that is, after receiving the transfer completed and channel halted interrupts.

Each host channel can be configured to support in/out and any type of periodic/nonperiodic transaction. Each host channel makes use of proper control (OTG\_HCCHARx), transfer configuration (OTG\_HCTSIZx) and status/interrupt (OTG\_HCINTx) registers with associated mask (OTG\_HCINTMSKx) registers.

#### Host channel control

- The following host channel controls are available to the application through the host channel-x characteristics register (OTG\_HCCHARx):
  - Channel enable/disable
  - Program the FS/LS speed of target USB peripheral
  - Program the address of target USB peripheral
  - Program the endpoint number of target USB peripheral
  - Program the transfer IN/OUT direction
  - Program the USB transfer type (control, bulk, interrupt, isochronous)
  - Program the maximum packet size (MPS)
  - Program the periodic transfer to be executed during odd/even frames

#### Host channel transfer

The host channel transfer size registers (OTG\_HCTSIZx) allow the application to program the transfer size parameters, and read the transfer status. Programming must be done before setting the channel enable bit in the host channel characteristics register. Once the endpoint is enabled the packet count field is read-only as the OTG\_FS core updates it according to the current transfer status.

- The following transfer parameters can be programmed:
  - transfer size in bytes
  - number of packets making up the overall transfer size
  - initial data PID

#### Host channel status/interrupt

The host channel-x interrupt register (OTG\_HCINTx) indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read these register when the host channels interrupt bit in the core interrupt register (HCINT bit in OTG\_GINTSTS) is set. Before the application can read these registers, it must first read the host all channels interrupt (OTG\_HAINT) register to get the exact channel number for the host channel-x interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the OTG\_HAINT and OTG\_GINTSTS registers.

The mask bits for each interrupt source of each channel are also available in the OTG\_HCINTMSKx register.

- The host core provides the following status checks and interrupt generation:
  - Transfer completed interrupt, indicating that the data transfer is complete on both the application (AHB) and USB sides
  - Channel has stopped due to transfer completed, USB transaction error or disable command from the application
  - Associated transmit FIFO is half or completely empty (IN endpoints)
  - ACK response received
  - NAK response received
  - STALL response received
  - USB transaction error due to CRC failure, timeout, bit stuff error, false EOP
  - Babble error
  - frame overrun
  - data toggle error

#### 47.7.4 Host scheduler

The host core features a built-in hardware scheduler which is able to autonomously re-order and manage the USB transaction requests posted by the application. At the beginning of each frame the host executes the periodic (isochronous and interrupt) transactions first, followed by the nonperiodic (control and bulk) transactions to achieve the higher level of priority granted to the isochronous and interrupt transfer types by the USB specification.

The host processes the USB transactions through request queues (one for periodic and one for nonperiodic). Each request queue can hold up to 8 entries. Each entry represents a pending transaction request from the application, and holds the IN or OUT channel number along with other information to perform a transaction on the USB. The order in which the requests are written to the queue determines the sequence of the transactions on the USB interface.

At the beginning of each frame, the host processes the periodic request queue first, followed by the nonperiodic request queue. The host issues an incomplete periodic transfer interrupt (IPXFR bit in OTG\_GINTSTS) if an isochronous or interrupt transaction scheduled for the current frame is still pending at the end of the current frame. The OTG\_FS core is fully responsible for the management of the periodic and nonperiodic request queues. The periodic transmit FIFO and queue status register (OTG\_HPTXSTS) and nonperiodic transmit FIFO and queue status register (OTG\_HNPTXSTS) are read-only registers which can be used by the application to read the status of each request queue. They contain:

- The number of free entries currently available in the periodic (nonperiodic) request queue (8 max)
- Free space currently available in the periodic (nonperiodic) Tx FIFO (out-transactions)
- IN/OUT token, host channel number and other status information.

As request queues can hold a maximum of 8 entries each, the application can push to schedule host transactions in advance with respect to the moment they physically reach the SB for a maximum of 8 pending periodic transactions plus 8 pending non-periodic transactions.

To post a transaction request to the host scheduler (queue) the application must check that there is at least 1 entry available in the periodic (nonperiodic) request queue by reading the

PTXQSAV bits in the OTG\_HNPTXSTS register or NPTQXSAV bits in the OTG\_HNPTXSTS register.

## 47.8 OTG\_FS SOF trigger

Figure 536. SOF connectivity (SOF trigger output to TIM and ITR1 connection)

The OTG\_FS core provides means to monitor, track and configure SOF framing in the host and peripheral, as well as an SOF pulse output connectivity feature.

Such utilities are especially useful for adaptive audio clock generation techniques, where the audio peripheral needs to synchronize to the isochronous stream provided by the PC, or the host needs to trim its framing rate according to the requirements of the audio peripheral.

### 47.8.1 Host SOFs

In host mode the number of PHY clocks occurring between the generation of two consecutive SOF (FS) or Keep-alive (LS) tokens is programmable in the host frame interval register (HFIR), thus providing application control over the SOF framing period. An interrupt is generated at any start of frame (SOF bit in OTG\_GINTSTS). The current frame number and the time remaining until the next SOF are tracked in the host frame number register (HFNUM).

A SOF pulse signal, is generated at any SOF starting token and with a width of 20 HCLK cycles. The SOF pulse is also internally connected to the input trigger of the timer, so that the input capture feature, the output compare feature and the timer can be triggered by the SOF pulse.

### 47.8.2 Peripheral SOFs

In device mode, the start of frame interrupt is generated each time an SOF token is received on the USB (SOF bit in OTG\_GINTSTS). The corresponding frame number can be read from the device status register (FNSOF bit in OTG\_DSTS). A SOF pulse signal with a width of 20 HCLK cycles is also generated. The SOF pulse signal is also internally connected to the TIM input trigger, so that the input capture feature, the output compare feature and the timer can be triggered by the SOF pulse.

The end of periodic frame interrupt (OTG\_GINTSTS/EOPF) is used to notify the application when 80%, 85%, 90% or 95% of the time frame interval elapsed depending on the periodic frame interval field in the device configuration register (PFIVL bit in OTG\_DCFG). This feature can be used to determine if all of the isochronous traffic for that frame is complete.

## 47.9 OTG\_FS low-power modes

[Table 321](#) below defines the STM32 low power modes and their compatibility with the OTG.

**Table 321. Compatibility of STM32 low power modes with the OTG**

| Mode    | Description                                                                                                 | USB compatibility                        |
|---------|-------------------------------------------------------------------------------------------------------------|------------------------------------------|
| Run     | MCU fully active                                                                                            | Required when USB not in suspend state.  |
| Sleep   | USB suspend exit causes the device to exit Sleep mode. Peripheral registers content is kept.                | Available while USB is in suspend state. |
| Stop    | USB suspend exit causes the device to exit Stop mode. Peripheral registers content is kept <sup>(1)</sup> . | Available while USB is in suspend state. |
| Standby | Powered-down. The peripheral must be reinitialized after exiting Standby mode.                              | Not compatible with USB applications.    |

1. Within Stop mode there are different possible settings. Some restrictions may also exist, refer to [Section 5: Power control \(PWR\)](#) to understand which (if any) restrictions apply when using OTG.

The following bits and procedures reduce power consumption.

The power consumption of the OTG PHY is controlled by two or three bits in the general core configuration register, depending on OTG revision supported.

- PHY power down (OTG\_GCCFG/PWRDWN)  
It switches on/off the full-speed transceiver module of the PHY. It must be preliminarily set to allow any USB operation
- V<sub>BUS</sub> detection enable (OTG\_GCCFG/VBDEN)  
It switches on/off the V<sub>BUS</sub> sensing comparators associated with OTG operations

Power reduction techniques are available while in the USB suspended state, when the USB session is not yet valid or the device is disconnected.

- Stop PHY clock (STPPCLK bit in OTG\_PCGCCTL)  
When setting the stop PHY clock bit in the clock gating control register, most of the 48 MHz clock domain internal to the OTG core is switched off by clock gating. The dynamic power consumption due to the USB clock switching activity is cut even if the 48 MHz clock input is kept running by the application  
Most of the transceiver is also disabled, and only the part in charge of detecting the asynchronous resume or remote wake-up event is kept alive.
- Gate HCLK (GATEHCLK bit in OTG\_PCGCCTL)  
When setting the Gate HCLK bit in the clock gating control register, most of the system clock domain internal to the OTG\_FS core is switched off by clock gating. Only the register read and write interface is kept alive. The dynamic power consumption due to

the USB clock switching activity is cut even if the system clock is kept running by the application for other purposes.

- USB system stop

When the OTG\_FS is in the USB suspended state, the application may decide to drastically reduce the overall power consumption by a complete shut down of all the clock sources in the system. USB System Stop is activated by first setting the Stop PHY clock bit and then configuring the system deep sleep mode in the power control system module (PWR).

The OTG\_FS core automatically reactivates both system and USB clocks by asynchronous detection of remote wake-up (as an host) or resume (as a device) signaling on the USB.

To save dynamic power, the USB data FIFO is clocked only when accessed by the OTG\_FS core.

## 47.10 OTG\_FS Dynamic update of the OTG\_HFIR register

The USB core embeds a dynamic trimming capability of SOF framing period in host mode allowing to synchronize an external device with the SOF frames.

When the OTG\_HFIR register is changed within a current SOF frame, the SOF period correction is applied in the next frame as described in [Figure 537](#).

For a dynamic update, it is required to set RLDCTRL=1.

**Figure 537. Updating OTG\_HFIR dynamically (RLDCTRL = 1)**

## 47.11 OTG\_FS data FIFOs

The USB system features 1.25 Kbytes of dedicated RAM with a sophisticated FIFO control mechanism. The packet FIFO controller module in the OTG\_FS core organizes RAM space into Tx FIFOs into which the application pushes the data to be temporarily stored before the USB transmission, and into a single Rx FIFO where the data received from the USB are temporarily stored before retrieval (popped) by the application. The number of instructed FIFOs and how these are organized inside the RAM depends on the device's role. In peripheral mode an additional Tx FIFO is instructed for each active IN endpoint. Any FIFO size is software configured to better meet the application requirements.

## 47.11.1 Peripheral FIFO architecture

**Figure 538. Device-mode FIFO address mapping and AHB FIFO access mapping**

### Peripheral Rx FIFO

The OTG peripheral uses a single receive FIFO that receives the data directed to all OUT endpoints. Received packets are stacked back-to-back until free space is available in the Rx FIFO. The status of the received packet (which contains the OUT endpoint destination number, the byte count, the data PID and the validity of the received data) is also stored by the core on top of the data payload. When no more space is available, host transactions are NACKed and an interrupt is received on the addressed endpoint. The size of the receive FIFO is configured in the receive FIFO size register (OTG\_GRXFSIZ).

The single receive FIFO architecture makes it more efficient for the USB peripheral to fill in the receive RAM buffer:

- All OUT endpoints share the same RAM buffer (shared FIFO)
- The OTG\_FS core can fill in the receive FIFO up to the limit for any host sequence of OUT tokens

The application keeps receiving the Rx FIFO non-empty interrupt (RXFLVL bit in OTG\_GINTSTS) as long as there is at least one packet available for download. It reads the packet information from the receive status read and pop register (OTG\_GRXSTSP) and finally pops data off the receive FIFO by reading from the endpoint-related pop address.

## Peripheral Tx FIFOs

The core has a dedicated FIFO for each IN endpoint. The application configures FIFO sizes by writing the endpoint 0 transmit FIFO size register (OTG\_DIEPTXF0) for IN endpoint0 and the device IN endpoint transmit FIFOx registers (OTG\_DIEPTXFx) for IN endpoint-x.

### 47.11.2 Host FIFO architecture

**Figure 539. Host-mode FIFO address mapping and AHB FIFO access mapping**

## Host Rx FIFO

The host uses one receiver FIFO for all periodic and nonperiodic transactions. The FIFO is used as a receive buffer to hold the received data (payload of the received packet) from the USB until it is transferred to the system memory. Packets received from any remote IN endpoint are stacked back-to-back until free space is available. The status of each received packet with the host channel destination, byte count, data PID and validity of the received data are also stored into the FIFO. The size of the receive FIFO is configured in the receive FIFO size register (OTG\_GRXF0SIZ).

The single receive FIFO architecture makes it highly efficient for the USB host to fill in the receive data buffer:

- All IN configured host channels share the same RAM buffer (shared FIFO)
- The OTG\_FS core can fill in the receive FIFO up to the limit for any sequence of IN tokens driven by the host software

The application receives the Rx FIFO not-empty interrupt as long as there is at least one packet available for download. It reads the packet information from the receive status read and pop register and finally pops the data off the receive FIFO.

## Host Tx FIFOs

The host uses one transmit FIFO for all non-periodic (control and bulk) OUT transactions and one transmit FIFO for all periodic (isochronous and interrupt) OUT transactions. FIFOs are used as transmit buffers to hold the data (payload of the transmit packet) to be transmitted over the USB. The size of the periodic (nonperiodic) Tx FIFO is configured in the host periodic (nonperiodic) transmit FIFO size OTG\_HPTXFSIZ / OTG\_HNPTXFSIZ register.

The two Tx FIFO implementation derives from the higher priority granted to the periodic type of traffic over the USB frame. At the beginning of each frame, the built-in host scheduler processes the periodic request queue first, followed by the nonperiodic request queue.

The two transmit FIFO architecture provides the USB host with separate optimization for periodic and nonperiodic transmit data buffer management:

- All host channels configured to support periodic (nonperiodic) transactions in the OUT direction share the same RAM buffer (shared FIFOs)
- The OTG\_FS core can fill in the periodic (nonperiodic) transmit FIFO up to the limit for any sequence of OUT tokens driven by the host software

The OTG\_FS core issues the periodic Tx FIFO empty interrupt (PTXFE bit in OTG\_GINTSTS) as long as the periodic Tx FIFO is half or completely empty, depending on the value of the periodic Tx FIFO empty level bit in the AHB configuration register (PTXFELVL bit in OTG\_GAHBCFG). The application can push the transmission data in advance as long as free space is available in both the periodic Tx FIFO and the periodic request queue. The host periodic transmit FIFO and queue status register (OTG\_HPTXSTS) can be read to know how much space is available in both.

OTG\_FS core issues the non periodic Tx FIFO empty interrupt (NPTXFE bit in OTG\_GINTSTS) as long as the nonperiodic Tx FIFO is half or completely empty depending on the non periodic Tx FIFO empty level bit in the AHB configuration register (TXFELVL bit in OTG\_GAHBCFG). The application can push the transmission data as long as free space is available in both the nonperiodic Tx FIFO and nonperiodic request queue. The host nonperiodic transmit FIFO and queue status register (OTG\_HNPTXSTS) can be read to know how much space is available in both.

## 47.11.3 FIFO RAM allocation

### Device mode

**Receive FIFO RAM allocation:** the application must allocate RAM for SETUP packets:

- 10 locations must be reserved in the receive FIFO to receive SETUP packets on control endpoint. The core does not use these locations, which are reserved for SETUP packets, to write any other data.
- One location is to be allocated for Global OUT NAK.
- Status information is written to the FIFO along with each received packet. Therefore, a minimum space of  $(\text{largest packet size} / 4) + 1$  must be allocated to receive packets. If multiple isochronous endpoints are enabled, then at least two  $(\text{largest packet size} / 4) + 1$  spaces must be allocated to receive back-to-back packets. Typically, two  $(\text{largest packet size} / 4) + 1$  spaces are recommended so that when the previous packet is being transferred to the CPU, the USB can receive the subsequent packet.
- Along with the last packet for each endpoint, transfer complete status information is also pushed to the FIFO. One location for each OUT endpoint is recommended.

Device RxFIFO =

$(5 * \text{number of control endpoints} + 8) + ((\text{largest USB packet used} / 4) + 1 \text{ for status information}) + (2 * \text{number of OUT endpoints}) + 1 \text{ for Global NAK}$

Example: The MPS is 1,024 bytes for a periodic USB packet and 512 bytes for a non-periodic USB packet. There are three OUT endpoints, three IN endpoints, one control endpoint, and three host channels.

Device RxFIFO =  $(5 * 1 + 8) + ((1,024 / 4) + 1) + (2 * 4) + 1 = 279$

**Transmit FIFO RAM allocation:** the minimum RAM space required for each IN endpoint Transmit FIFO is the maximum packet size for that particular IN endpoint.

*Note: More space allocated in the transmit IN endpoint FIFO results in better performance on the USB.*

## Host mode

Receive FIFO RAM allocation:

Status information is written to the FIFO along with each received packet. Therefore, a minimum space of  $(\text{largest packet size} / 4) + 1$  must be allocated to receive packets. If multiple isochronous channels are enabled, then at least two  $(\text{largest packet size} / 4) + 1$  spaces must be allocated to receive back-to-back packets. Typically, two  $(\text{largest packet size} / 4) + 1$  spaces are recommended so that when the previous packet is being transferred to the CPU, the USB can receive the subsequent packet.

Along with the last packet in the host channel, transfer complete status information is also pushed to the FIFO. So one location must be allocated for this.

Host RxFIFO =  $(\text{largest USB packet used} / 4) + 1 \text{ for status information} + 1 \text{ transfer complete}$

Example: Host RxFIFO =  $((1,024 / 4) + 1) + 1 = 258$

Transmit FIFO RAM allocation:

The minimum amount of RAM required for the host Non-periodic Transmit FIFO is the largest maximum packet size among all supported non-periodic OUT channels.

Typically, two largest packet sizes worth of space is recommended, so that when the current packet is under transfer to the USB, the CPU can get the next packet.

Non-Periodic TxFIFO =  $\text{largest non-periodic USB packet used} / 4$

Example: Non-Periodic TxFIFO =  $(512 / 4) = 128$

The minimum amount of RAM required for host periodic Transmit FIFO is the largest maximum packet size out of all the supported periodic OUT channels. If there is at least one isochronous OUT endpoint, then the space must be at least two times the maximum packet size of that channel.

Host Periodic TxFIFO =  $\text{largest periodic USB packet used} / 4$

Example: Host Periodic TxFIFO =  $(1,024 / 4) = 256$

*Note: More space allocated in the Transmit Non-periodic FIFO results in better performance on the USB.*

## 47.12 OTG\_FS system performance

Best USB and system performance is achieved owing to the large RAM buffers, the highly configurable FIFO sizes, the quick 32-bit FIFO access through AHB push/pop registers and, especially, the advanced FIFO control mechanism. Indeed, this mechanism allows the OTG\_FS to fill in the available RAM space at best regardless of the current USB sequence. With these features:

- The application gains good margins to calibrate its intervention in order to optimize the CPU bandwidth usage:
  - It can accumulate large amounts of transmission data in advance compared to when they are effectively sent over the USB
  - It benefits of a large time margin to download data from the single receive FIFO
- The USB core is able to maintain its full operating rate, that is to provide maximum full-speed bandwidth with a great margin of autonomy versus application intervention:
  - It has a large reserve of transmission data at its disposal to autonomously manage the sending of data over the USB
  - It has a lot of empty space available in the receive buffer to autonomously fill it in with the data coming from the USB

As the OTG\_FS core is able to fill in the 1.25-Kbyte RAM buffer very efficiently, and as 1.25-Kbyte of transmit/receive data is more than enough to cover a full speed frame, the USB system is able to withstand the maximum full-speed data rate for up to one USB frame (1 ms) without any CPU intervention.

## 47.13 OTG\_FS interrupts

When the OTG\_FS controller is operating in one mode, either device or host, the application must not access registers from the other mode. If an illegal access occurs, a mode mismatch interrupt is generated and reflected in the core interrupt register (MMIS bit in the OTG\_GINTSTS register). When the core switches from one mode to the other, the registers in the new mode of operation must be reprogrammed as they would be after a power-on reset.

*Figure 540* shows the interrupt hierarchy.

Figure 540. Interrupt hierarchy

1. OTG\_FS\_WKUP becomes active (high state) when resume condition occurs during L1 SLEEP or L2 SUSPEND states.

## 47.14 OTG\_FS control and status registers

By reading from and writing to the control and status registers (CSRs) through the AHB slave interface, the application controls the OTG\_FS controller. These registers are 32 bits wide, and the addresses are 32-bit block aligned. The OTG\_FS registers must be accessed by words (32 bits).

CSRs are classified as follows:

- Core global registers
- Host-mode registers
- Host global registers
- Host port CSRs
- Host channel-specific registers
- Device-mode registers
- Device global registers
- Device endpoint-specific registers
- Power and clock-gating registers
- Data FIFO (DFIFO) access registers

Only the core global, power and clock-gating, data FIFO access, and host port control and status registers can be accessed in both host and device modes. When the OTG\_FS controller is operating in one mode, either device or host, the application must not access registers from the other mode. If an illegal access occurs, a mode mismatch interrupt is generated and reflected in the core interrupt register (MMIS bit in the OTG\_GINTSTS register). When the core switches from one mode to the other, the registers in the new mode of operation must be reprogrammed as they would be after a power-on reset.

### 47.14.1 CSR memory map

The host and device mode registers occupy different addresses. All registers are implemented in the AHB clock domain.

#### Global CSR map

These registers are available in both host and device modes.

**Table 322. Core global control and status registers (CSRs)**

| Acronym     | Address offset | Register name                                                                  |

**Data FIFO (DFIFO) access register map**

These registers, available in both host and device modes, are used to read or write the FIFO space for a specific endpoint or a channel, in a given direction. If a host channel is of type IN, the FIFO can only be read on the channel. Similarly, if a host channel is of type OUT, the FIFO can only be written on the channel.

**Table 325. Data FIFO (DFIFO) access register map**

| FIFO access register section                                                                                                                                                              | Offset address | Access |

## 47.15 OTG\_FS registers

These registers are available in both host and device modes, and do not need to be reprogrammed when switching between these modes.

Bit values in the register descriptions are expressed in binary unless otherwise specified.

### 47.15.1 OTG control and status register (OTG\_GOTGCTL)

Address offset: 0x000

Reset value: 0x0001 0000

The OTG\_GOTGCTL register controls the behavior and reflects the status of the OTG function of the core.

|      |      |      |      |            |             |           |            |              |             |              |             |               |              |      |            |

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 **CURMOD**: Current mode of operation

Indicates the current mode (host or device).

0: Device mode

1: Host mode

Bit 20 **OTGVER**: OTG version

Selects the OTG revision.

0: OTG Version 1.3. OTG1.3 is obsolete for new product development.

1: OTG Version 2.0. In this version the core supports only data line pulsing for SRP.

Bit 19 **BSVLD**: B-session valid

Indicates the device mode transceiver status.

0: B-session is not valid.

1: B-session is valid.

In OTG mode, the user can use this bit to determine if the device is connected or disconnected.

*Note: Only accessible in device mode.*

Bit 18 **ASVLD**: A-session valid

Indicates the host mode transceiver status.

0: A-session is not valid

1: A-session is valid

*Note: Only accessible in host mode.*

Bit 17 **DBCT**: Long/short debounce time

Indicates the debounce time of a detected connection.

0: Long debounce time, used for physical connections (100 ms + 2.5  $\mu$ s)

1: Short debounce time, used for soft connections (2.5  $\mu$ s)

*Note: Only accessible in host mode.*

Bit 16 **CIDSTS**: Connector ID status

Indicates the connector ID status on a connect event.

0: The OTG\_FS controller is in A-device mode

1: The OTG\_FS controller is in B-device mode

*Note: Accessible in both device and host modes.*

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **EHEN**: Embedded host enable

It is used to select between OTG A device state machine and embedded host state machine.

0: OTG A device state machine is selected

1: Embedded host state machine is selected

Bit 11 **DHNPEN**: Device HNP enabled

The application sets this bit when it successfully receives a SetFeature.SetHNPEnable command from the connected USB host.

0: HNP is not enabled in the application

1: HNP is enabled in the application

*Note: Only accessible in device mode.*

Bit 10 **HSHPEN**: host set HNP enable

The application sets this bit when it has successfully enabled HNP (using the SetFeature.SetHNPEnable command) on the connected device.

0: Host Set HNP is not enabled

1: Host Set HNP is enabled

*Note: Only accessible in host mode.*

Bit 9 **HNPRQ**: HNP request

The application sets this bit to initiate an HNP request to the connected USB host. The application can clear this bit by writing a 0 when the host negotiation success status change bit in the OTG\_GOTGINT register (HNSSCHG bit in OTG\_GOTGINT) is set. The core clears this bit when the HNSSCHG bit is cleared.

0: No HNP request

1: HNP request

*Note: Only accessible in device mode.*

Bit 8 **HNGSCS**: Host negotiation success

The core sets this bit when host negotiation is successful. The core clears this bit when the HNP request (HNPRQ) bit in this register is set.

0: Host negotiation failure

1: Host negotiation success

*Note: Only accessible in device mode.*

Bit 7 **BVALOVAL**: B-peripheral session valid override value.

This bit is used to set override value for Bvalid signal when BVALOEN bit is set.

0: Bvalid value is '0' when BVALOEN = 1

1: Bvalid value is '1' when BVALOEN = 1

*Note: Only accessible in device mode.*

Bit 6 **BVALOEN**: B-peripheral session valid override enable.

This bit is used to enable/disable the software to override the Bvalid signal using the BVALOVAL bit.

0: Override is disabled and Bvalid signal from the respective PHY selected is used internally by the core

1: Internally Bvalid received from the PHY is overridden with BVALOVAL bit value

*Note: Only accessible in device mode.*

Bit 5 **AVALOVAL**: A-peripheral session valid override value.

This bit is used to set override value for Avalid signal when AVALOEN bit is set.

0: Avalid value is '0' when AVALOEN = 1

1: Avalid value is '1' when AVALOEN = 1

*Note: Only accessible in host mode.*

Bit 4 **AVALOEN**: A-peripheral session valid override enable.

This bit is used to enable/disable the software to override the Avalid signal using the AVALOVAL bit.

0: Override is disabled and Avalid signal from the respective PHY selected is used internally by the core

1: Internally Avalid received from the PHY is overridden with AVALOVAL bit value

*Note: Only accessible in host mode.*

Bit 3 **VBVALOVAL**:  $V_{BUS}$  valid override value.

This bit is used to set override value for vbusvalid signal when VBVALOEN bit is set.

0: vbusvalid value is '0' when VBVALOEN = 1

1: vbusvalid value is '1' when VBVALOEN = 1

*Note: Only accessible in host mode.*

Bit 2 **VBVALOEN**:  $V_{BUS}$  valid override enable.

This bit is used to enable/disable the software to override the vbusvalid signal using the VBVALOVAL bit.

0: Override is disabled and vbusvalid signal from the respective PHY selected is used internally by the core

1: Internally vbusvalid received from the PHY is overridden with VBVALOVAL bit value

*Note: Only accessible in host mode.*

Bit 1 **SRQ**: Session request

The application sets this bit to initiate a session request on the USB. The application can clear this bit by writing a 0 when the host negotiation success status change bit in the OTG\_GOTGINT register (HNSSCHG bit in OTG\_GOTGINT) is set. The core clears this bit when the HNSSCHG bit is cleared.

If the user uses the USB 1.1 full-speed serial transceiver interface to initiate the session request, the application must wait until  $V_{BUS}$  discharges to 0.2 V, after the B-session valid bit in this register (BSVLD bit in OTG\_GOTGCTL) is cleared.

0: No session request

1: Session request

*Note: Only accessible in device mode.*

Bit 0 **SRQSCS**: Session request success

The core sets this bit when a session request initiation is successful.

0: Session request failure

1: Session request success

*Note: Only accessible in device mode.*

### 47.15.2 OTG interrupt register (OTG\_GOTGINT)

Address offset: 0x04

Reset value: 0x0000 0000

The application reads this register whenever there is an OTG interrupt and clears the bits in this register to clear the OTG interrupt.

Bits 31:20 Reserved, must be kept at reset value.

Bit 19 **DBC DNE**: Debounce done

The core sets this bit when the debounce is completed after the device connect. The application can start driving USB reset after seeing this interrupt. This bit is only valid when the HNP Capable or SRP Capable bit is set in the OTG\_GUSBCFG register (HNPCAP bit or SRPCAP bit in OTG\_GUSBCFG, respectively).

*Note: Only accessible in host mode.*

Bit 18 **ADTOCHG**: A-device timeout change

The core sets this bit to indicate that the A-device has timed out while waiting for the B-device to connect.

*Note: Accessible in both device and host modes.*

Bit 17 **HNGDET**: Host negotiation detected

The core sets this bit when it detects a host negotiation request on the USB.

*Note: Accessible in both device and host modes.*

Bits 16:10 Reserved, must be kept at reset value.

Bit 9 **HNSSCHG**: Host negotiation success status change

The core sets this bit on the success or failure of a USB host negotiation request. The application must read the host negotiation success bit of the OTG\_GOTGCTL register (HNGSCS bit in OTG\_GOTGCTL) to check for success or failure.

*Note: Accessible in both device and host modes.*

Bits 7:3 Reserved, must be kept at reset value.

Bit 8 **SRSSCHG**: Session request success status change

The core sets this bit on the success or failure of a session request. The application must read the session request success bit in the OTG\_GOTGCTL register (SRQSCS bit in OTG\_GOTGCTL) to check for success or failure.

*Note: Accessible in both device and host modes.*

Bit 2 **SEDET**: Session end detected

The core sets this bit to indicate that the level of the voltage on  $V_{BUS}$  is no longer valid for a B-Peripheral session when  $V_{BUS} < 0.8$  V.

*Note: Accessible in both device and host modes.*

Bits 1:0 Reserved, must be kept at reset value.

### 47.15.3 OTG AHB configuration register (OTG\_GAHBCFG)

Address offset: 0x008

Reset value: 0x0000 0000

This register can be used to configure the core after power-on or a change in mode. This register mainly contains AHB system-related configuration parameters. Do not change this register after the initial programming. The application must program this register before starting any transactions on either the AHB or the USB.

|      |      |      |      |      |      |      |              |             |      |      |      |      |      |      |             |
|------|------|------|------|------|------|------|--------------|-------------|------|------|------|------|------|------|-------------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24           | 23          | 22   | 21   | 20   | 19   | 18   | 17   | 16          |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.         | Res.        | Res. | Res. | Res. | Res. | Res. | Res. | Res.        |
|      |      |      |      |      |      |      |              |             |      |      |      |      |      |      |             |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8            | 7           | 6    | 5    | 4    | 3    | 2    | 1    | 0           |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | PTXFE<br>LVL | TXFE<br>LVL | Res. | Res. | Res. | Res. | Res. | Res. | GINT<br>MSK |
|      |      |      |      |      |      |      | rw           | rw          |      |      |      |      |      |      | rw          |

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **PTXFELVL**: Periodic Tx FIFO empty level

Indicates when the periodic Tx FIFO empty interrupt bit in the OTG\_GINTSTS register (PTXFE bit in OTG\_GINTSTS) is triggered.

0: PTXFE (in OTG\_GINTSTS) interrupt indicates that the Periodic Tx FIFO is half empty

1: PTXFE (in OTG\_GINTSTS) interrupt indicates that the Periodic Tx FIFO is completely empty

*Note: Only accessible in host mode.*

Bit 7 **TXFELVL**: Tx FIFO empty level

In device mode, this bit indicates when IN endpoint Transmit FIFO empty interrupt (TXFE in OTG\_DIEPINTx) is triggered:

0: The TXFE (in OTG\_DIEPINTx) interrupt indicates that the IN endpoint Tx FIFO is half empty

1: The TXFE (in OTG\_DIEPINTx) interrupt indicates that the IN endpoint Tx FIFO is completely empty

In host mode, this bit indicates when the nonperiodic Tx FIFO empty interrupt (NPTXFE bit in OTG\_GINTSTS) is triggered:

0: The NPTXFE (in OTG\_GINTSTS) interrupt indicates that the nonperiodic Tx FIFO is half empty

1: The NPTXFE (in OTG\_GINTSTS) interrupt indicates that the nonperiodic Tx FIFO is completely empty

Bits 6:1 Reserved, must be kept at reset value.

Bit 0 **GINTMSK**: Global interrupt mask

The application uses this bit to mask or unmask the interrupt line assertion to itself.

Irrespective of this bit's setting, the interrupt status registers are updated by the core.

0: Mask the interrupt assertion to the application.

1: Unmask the interrupt assertion to the application.

*Note: Accessible in both device and host modes.*

#### 47.15.4 OTG USB configuration register (OTG\_GUSBCFG)

Address offset: 0x00C

Reset value: 0x0000 1440

This register can be used to configure the core after power-on or a changing to host mode or device mode. It contains USB and USB-PHY related configuration parameters. The application must program this register before starting any transactions on either the AHB or the USB. Do not make changes to this register after the initial programming.

|      |           |           |      |      |      |            |            |      |            |      |      |      |            |      |      |
|------|-----------|-----------|------|------|------|------------|------------|------|------------|------|------|------|------------|------|------|

|      | rw        | rw        |      |      |      |            |            |      |            |      |      |      |            |      |      |
| 15   | 14        | 13        | 12   | 11   | 10   | 9          | 8          | 7    | 6          | 5    | 4    | 3    | 2          | 1    | 0    |
| Res. | Res.      | TRDT[3:0] |      |      |      | HNP<br>CAP | SRP<br>CAP | Res. | PHY<br>SEL | Res. | Res. | Res. | TODAL[2:0] |      |      |
|      |           | rw        | rw   | rw   | rw   | rw         | rw         |      | r          |      |      |      | rw         | rw   | rw   |

Bit 31 Reserved, must be kept at reset value.

Bit 30 **FDMOD**: Force device mode

Writing a 1 to this bit, forces the core to device mode irrespective of the OTG\_ID input pin.

0: Normal mode

1: Force device mode

After setting the force bit, the application must wait at least 25 ms before the change takes effect.

*Note: Accessible in both device and host modes.*

Bit 29 **FHMOD**: Force host mode

Writing a 1 to this bit, forces the core to host mode irrespective of the OTG\_ID input pin.

0: Normal mode

1: Force host mode

After setting the force bit, the application must wait at least 25 ms before the change takes effect.

*Note: Accessible in both device and host modes.*

Bits 28:26 Reserved, must be kept at reset value.

Bits 25:23 Reserved, must be kept at reset value.

Bit 22 Reserved, must be kept at reset value.

Bits 21:16 Reserved, must be kept at reset value.

Bit 15 Reserved, must be kept at reset value.

Bit 14 Reserved, must be kept at reset value.

Bits 13:10 **TRDT[3:0]**: USB turnaround time

These bits are used to set the turnaround time in PHY clocks. They must be configured according to [Table 327: TRDT values](#), depending on the application AHB frequency. Higher TRDT values allow stretching the USB response time to IN tokens in order to compensate for longer AHB read access latency to the data FIFO.

*Note: Only accessible in device mode.*

Bit 9 **HNPCAP**: HNP-capable

The application uses this bit to control the OTG\_FS controller's HNP capabilities.

0: HNP capability is not enabled.

1: HNP capability is enabled.

*Note:* Accessible in both device and host modes.

Bit 8 **SRPCAP**: SRP-capable

The application uses this bit to control the OTG\_FS controller's SRP capabilities. If the core operates as a non-SRP-capable

B-device, it cannot request the connected A-device (host) to activate  $V_{BUS}$  and start a session.

0: SRP capability is not enabled.

1: SRP capability is enabled.

*Note:* Accessible in both device and host modes.

## Bit 7 Reserved, must be kept at reset value.

Bit 6 **PHYSEL**: Full Speed serial transceiver mode select

This bit is always 1 with read-only access.

## Bit 5 Reserved, must be kept at reset value.

## Bit 4 Reserved, must be kept at reset value.

## Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **TOTAL[2:0]**: FS timeout calibration

The number of PHY clocks that the application programs in this field is added to the full-speed interpacket timeout duration in the core to account for any additional delays introduced by the PHY. This can be required, because the delay introduced by the PHY in generating the line state condition can vary from one PHY to another.

The USB standard timeout value for full-speed operation is 16 to 18 (inclusive) bit times. The application must program this field based on the speed of enumeration. The number of bit times added per PHY clock is 0.25 bit times.

Table 327. TRDT values

| AHB frequency range (MHz) |      | TRDT minimum value |
|---------------------------|------|--------------------|
| Min                       | Max  |                    |
| 14.2                      | 15   | 0xF                |
| 15                        | 16   | 0xE                |
| 16                        | 17.2 | 0xD                |
| 17.2                      | 18.5 | 0xC                |
| 18.5                      | 20   | 0xB                |
| 20                        | 21.8 | 0xA                |
| 21.8                      | 24   | 0x9                |
| 24                        | 27.5 | 0x8                |
| 27.5                      | 32   | 0x7                |
| 32                        | -    | 0x6                |

### 47.15.5 OTG reset register (OTG\_GRSTCTL)

Address offset: 0x10

Reset value: 0x8000 0000

The application uses this register to reset various hardware features inside the core.

|         |      |      |      |      |             |      |      |      |      |          |          |      |       |       |       |
|---------|------|------|------|------|-------------|------|------|------|------|----------|----------|------|-------|-------|-------|

| r       |      |      |      |      |             |      |      |      |      |          |          |      |       |       |       |
| 15      | 14   | 13   | 12   | 11   | 10          | 9    | 8    | 7    | 6    | 5        | 4        | 3    | 2     | 1     | 0     |
| Res.    | Res. | Res. | Res. | Res. | TXFNUM[4:0] |      |      |      |      | TXF FLSH | RXF FLSH | Res. | FCRST | PSRST | CSRST |
|         |      |      |      |      | rw          | rw   | rw   | rw   | rw   | rs       | rs       |      | rs    | rs    | r     |

Bit 31 **AHBIDL**: AHB master idle

Indicates that the AHB master state machine is in the Idle condition.

*Note: Accessible in both device and host modes.*

Bits 30:11 Reserved, must be kept at reset value.

Bits 10:6 **TXFNUM[4:0]**: Tx FIFO number

This is the FIFO number that must be flushed using the Tx FIFO Flush bit. This field must not be changed until the core clears the Tx FIFO Flush bit.

00000:

- Non-periodic Tx FIFO flush in host mode
- Tx FIFO 0 flush in device mode

00001:

- Periodic Tx FIFO flush in host mode
- Tx FIFO 1 flush in device mode

00010: Tx FIFO 2 flush in device mode

...

01111: Tx FIFO 15 flush in device mode

10000: Flush all the transmit FIFOs in device or host mode.

*Note: Accessible in both device and host modes.*

Bit 5 **TXFFLSH**: Tx FIFO flush

This bit selectively flushes a single or all transmit FIFOs, but cannot do so if the core is in the midst of a transaction.

The application must write this bit only after checking that the core is neither writing to the Tx FIFO nor reading from the Tx FIFO. Verify using these registers:

Read—NAK Effective interrupt ensures the core is not reading from the FIFO

Write—AHBIDL bit in OTG\_GRSTCTL ensures the core is not writing anything to the FIFO.

Flushing is normally recommended when FIFOs are reconfigured. FIFO flushing is also recommended during device endpoint disable. The application must wait until the core clears this bit before performing any operations. This bit takes eight clocks to clear, using the slower clock of phy\_clk or hclk.

*Note: Accessible in both device and host modes.*

**Bit 4 RXFFLSH:** Rx FIFO flush

The application can flush the entire Rx FIFO using this bit, but must first ensure that the core is not in the middle of a transaction.

The application must only write to this bit after checking that the core is neither reading from the Rx FIFO nor writing to the Rx FIFO.

The application must wait until the bit is cleared before performing any other operations. This bit requires 8 clocks (slowest of PHY or AHB clock) to clear.

*Note:* Accessible in both device and host modes.

**Bit 3** Reserved, must be kept at reset value.**Bit 2 FCRST:** Host frame counter reset

The application writes this bit to reset the frame number counter inside the core. When the frame counter is reset, the subsequent SOF sent out by the core has a frame number of 0.

When application writes '1' to the bit, it might not be able to read back the value as it gets cleared by the core in a few clock cycles.

*Note:* Only accessible in host mode.

**Bit 1 PSRST:** Partial soft reset

Resets the internal state machines but keeps the enumeration info. Can be used to recover some specific PHY errors.

*Note:* Accessible in both device and host modes.

*Note:* This bit is available in STM32L49x/L4Ax products, reserved otherwise.

**Bit 0 CSRST:** Core soft reset

Resets the HCLK and PHY clock domains as follows:

Clears the interrupts and all the CSR register bits except for the following bits:

- GATEHCLK bit in OTG\_PCGCCTL
- STPPCLK bit in OTG\_PCGCCTL
- FSLSPCS bits in OTG\_HCFG
- DSPD bit in OTG\_DCFG
- SDIS bit in OTG\_DCTL
- OTG\_GCCFG register
- OTG\_GPWRDN register
- OTG\_GADPCTL register

All module state machines (except for the AHB slave unit) are reset to the Idle state, and all the transmit FIFOs and the receive FIFO are flushed.

Any transactions on the AHB Master are terminated as soon as possible, after completing the last data phase of an AHB transfer. Any transactions on the USB are terminated immediately.

When ADP feature is enabled, the power management module is not reset by the core soft reset.

The application can write to this bit any time it wants to reset the core. This is a self-clearing bit and the core clears this bit after all the necessary logic is reset in the core, which can take several clocks, depending on the current state of the core. Once this bit has been cleared, the software must wait at least 3 PHY clocks before accessing the PHY domain (synchronization delay). The software must also check that bit 31 in this register is set to 1 (AHB Master is Idle) before starting any operation.

Typically, the software reset is used during software development and also when the user dynamically changes the PHY selection bits in the above listed USB configuration registers. When the user changes the PHY, the corresponding clock for the PHY is selected and used in the PHY domain. Once a new clock is selected, the PHY domain has to be reset for proper operation.

*Note:* Accessible in both device and host modes.

### 47.15.6 OTG core interrupt register (OTG\_GINTSTS)

Address offset: 0x014

Reset value: 0x0400 0020

This register interrupts the application for system-level events in the current mode (device mode or host mode).

Some of the bits in this register are valid only in host mode, while others are valid in device mode only. This register also indicates the current mode. To clear the interrupt status bits of the rc\_w1 type, the application must write 1 into the bit.

The FIFO status interrupts are read-only; once software reads from or writes to the FIFO while servicing these interrupts, FIFO interrupt conditions are cleared automatically.

The application must clear the OTG\_GINTSTS register at initialization before unmasking the interrupt bit to avoid any interrupts generated prior to initialization.

| 31          | 30          | 29          | 28          | 27          | 26    | 25    | 24          | 23               | 22               | 21                                 | 20           | 19         | 18         | 17    | 16   |

Bit 31 **WKUPINT**: Resume/remote wake-up detected interrupt

Wake-up interrupt during suspend(L2) or LPM(L1) state.

– During suspend(L2):

In device mode, this interrupt is asserted when a resume is detected on the USB. In host mode, this interrupt is asserted when a remote wake-up is detected on the USB.

– During LPM(L1):

This interrupt is asserted for either host initiated resume or device initiated remote wake-up on USB.

*Note: Accessible in both device and host modes.*

Bit 30 **SRQINT**: Session request/new session detected interrupt

In host mode, this interrupt is asserted when a session request is detected from the device. In device mode, this interrupt is asserted when  $V_{BUS}$  is in the valid range for a B-peripheral device. Accessible in both device and host modes.

Bit 29 **DISCINT**: Disconnect detected interrupt

Asserted when a device disconnect is detected.

*Note: Only accessible in host mode.*

Bit 28 **CIDSCHG**: Connector ID status change

The core sets this bit when there is a change in connector ID status.

*Note: Accessible in both device and host modes.*

**Bit 27 LPMINT:** LPM interrupt

In device mode, this interrupt is asserted when the device receives an LPM transaction and responds with a non-ERRORed response.

In host mode, this interrupt is asserted when the device responds to an LPM transaction with a non-ERRORed response or when the host core has completed LPM transactions for the programmed number of times (RETRYCNT bit in OTG\_GLPMCFG).

This field is valid only if the LPMEN bit in OTG\_GLPMCFG is set to 1.

**Bit 26 PTXFE:** Periodic Tx FIFO empty

Asserted when the periodic transmit FIFO is either half or completely empty and there is space for at least one entry to be written in the periodic request queue. The half or completely empty status is determined by the periodic Tx FIFO empty level bit in the OTG\_GAHBCFG register (PTXFELVL bit in OTG\_GAHBCFG).

*Note: Only accessible in host mode.*

**Bit 25 HCINT:** Host channels interrupt

The core sets this bit to indicate that an interrupt is pending on one of the channels of the core (in host mode). The application must read the OTG\_HAINT register to determine the exact number of the channel on which the interrupt occurred, and then read the corresponding OTG\_HCINTx register to determine the exact cause of the interrupt. The application must clear the appropriate status bit in the OTG\_HCINTx register to clear this bit.

*Note: Only accessible in host mode.*

**Bit 24 HPRTINT:** Host port interrupt

The core sets this bit to indicate a change in port status of one of the OTG\_FS controller ports in host mode. The application must read the OTG\_HPRT register to determine the exact event that caused this interrupt. The application must clear the appropriate status bit in the OTG\_HPRT register to clear this bit.

*Note: Only accessible in host mode.*

**Bit 23 RSTDET:** Reset detected interrupt

In device mode, this interrupt is asserted when a reset is detected on the USB in partial power-down mode when the device is in suspend.

*Note: Only accessible in device mode.*

**Bit 22** Reserved, must be kept at reset value.**Bit 21 IPXFR:** Incomplete periodic transfer

In host mode, the core sets this interrupt bit when there are incomplete periodic transactions still pending, which are scheduled for the current frame.

**INCOMPISOOUT:** Incomplete isochronous OUT transfer

In device mode, the core sets this interrupt to indicate that there is at least one isochronous OUT endpoint on which the transfer is not completed in the current frame. This interrupt is asserted along with the End of periodic frame interrupt (EOPF) bit in this register.

**Bit 20 IISOXFR:** Incomplete isochronous IN transfer

The core sets this interrupt to indicate that there is at least one isochronous IN endpoint on which the transfer is not completed in the current frame. This interrupt is asserted along with the End of periodic frame interrupt (EOPF) bit in this register.

*Note: Only accessible in device mode.*

**Bit 19 OEPINT:** OUT endpoint interrupt

The core sets this bit to indicate that an interrupt is pending on one of the OUT endpoints of the core (in device mode). The application must read the OTG\_DAIN register to determine the exact number of the OUT endpoint on which the interrupt occurred, and then read the corresponding OTG\_DOEPINTx register to determine the exact cause of the interrupt. The application must clear the appropriate status bit in the corresponding OTG\_DOEPINTx register to clear this bit.

*Note: Only accessible in device mode.*

**Bit 18 IEPINT:** IN endpoint interrupt

The core sets this bit to indicate that an interrupt is pending on one of the IN endpoints of the core (in device mode). The application must read the OTG\_DAIN register to determine the exact number of the IN endpoint on which the interrupt occurred, and then read the corresponding OTG\_DIEPINTx register to determine the exact cause of the interrupt. The application must clear the appropriate status bit in the corresponding OTG\_DIEPINTx register to clear this bit.

*Note: Only accessible in device mode.*

Bits 17:16 Reserved, must be kept at reset value.

**Bit 15 EOPF:** End of periodic frame interrupt

Indicates that the period specified in the periodic frame interval field of the OTG\_DCFG register (PFIVL bit in OTG\_DCFG) has been reached in the current frame.

*Note: Only accessible in device mode.*

**Bit 14 ISOODRP:** Isochronous OUT packet dropped interrupt

The core sets this bit when it fails to write an isochronous OUT packet into the Rx FIFO because the Rx FIFO does not have enough space to accommodate a maximum size packet for the isochronous OUT endpoint.

*Note: Only accessible in device mode.*

**Bit 13 ENUMDNE:** Enumeration done

The core sets this bit to indicate that speed enumeration is complete. The application must read the OTG\_DSTS register to obtain the enumerated speed.

*Note: Only accessible in device mode.*

**Bit 12 USBRST:** USB reset

The core sets this bit to indicate that a reset is detected on the USB.

*Note: Only accessible in device mode.*

**Bit 11 USBSUSP:** USB suspend

The core sets this bit to indicate that a suspend was detected on the USB. The core enters the suspended state when there is no activity on the data lines for an extended period of time.

*Note: Only accessible in device mode.*

**Bit 10 ESUSP:** Early suspend

The core sets this bit to indicate that an Idle state has been detected on the USB for 3 ms.

*Note: Only accessible in device mode.*

Bits 9:8 Reserved, must be kept at reset value.

**Bit 7 GONAKEFF:** Global OUT NAK effective

Indicates that the Set global OUT NAK bit in the OTG\_DCTL register (SGONAK bit in OTG\_DCTL), set by the application, has taken effect in the core. This bit can be cleared by writing the Clear global OUT NAK bit in the OTG\_DCTL register (CGONAK bit in OTG\_DCTL).

*Note: Only accessible in device mode.*

**Bit 6 GINAKEFF:** Global IN non-periodic NAK effective

Indicates that the Set global non-periodic IN NAK bit in the OTG\_DCTL register (SGINAK bit in OTG\_DCTL), set by the application, has taken effect in the core. That is, the core has sampled the Global IN NAK bit set by the application. This bit can be cleared by clearing the Clear global non-periodic IN NAK bit in the OTG\_DCTL register (CGINAK bit in OTG\_DCTL).

This interrupt does not necessarily mean that a NAK handshake is sent out on the USB. The STALL bit takes precedence over the NAK bit.

*Note: Only accessible in device mode.*

**Bit 5 NPTXFE:** Non-periodic Tx FIFO empty

This interrupt is asserted when the non-periodic Tx FIFO is either half or completely empty, and there is space for at least one entry to be written to the non-periodic transmit request queue. The half or completely empty status is determined by the non-periodic Tx FIFO empty level bit in the OTG\_GAHBCFG register (TXFELVL bit in OTG\_GAHBCFG).

*Note: Accessible in host mode only.*

**Bit 4 RXFLVL:** Rx FIFO non-empty

Indicates that there is at least one packet pending to be read from the Rx FIFO.

*Note: Accessible in both host and device modes.*

**Bit 3 SOF:** Start of frame

In host mode, the core sets this bit to indicate that an SOF (FS), or Keep-Alive (LS) is transmitted on the USB. The application must write a 1 to this bit to clear the interrupt.

In device mode, the core sets this bit to indicate that an SOF token has been received on the USB. The application can read the OTG\_DSTS register to get the current frame number. This interrupt is seen only when the core is operating in FS.

*Note: This register may return '1' if read immediately after power on reset. If the register bit reads '1' immediately after power on reset it does not indicate that an SOF has been sent (in case of host mode) or SOF has been received (in case of device mode). The read value of this interrupt is valid only after a valid connection between host and device is established. If the bit is set after power on reset the application can clear the bit.*

*Note: Accessible in both host and device modes.*

**Bit 2 OTGINT:** OTG interrupt

The core sets this bit to indicate an OTG protocol event. The application must read the OTG interrupt status (OTG\_GOTGINT) register to determine the exact event that caused this interrupt. The application must clear the appropriate status bit in the OTG\_GOTGINT register to clear this bit.

*Note: Accessible in both host and device modes.*

**Bit 1 MMIS:** Mode mismatch interrupt

The core sets this bit when the application is trying to access:

- A host mode register, when the core is operating in device mode
- A device mode register, when the core is operating in host mode

The register access is completed on the AHB with an OKAY response, but is ignored by the core internally and does not affect the operation of the core.

*Note: Accessible in both host and device modes.*

**Bit 0 CMOD:** Current mode of operation

Indicates the current mode.

0: Device mode

1: Host mode

*Note: Accessible in both host and device modes.*

### 47.15.7 OTG interrupt mask register (OTG\_GINTMSK)

Address offset: 0x018

Reset value: 0x0000 0000

This register works with the core interrupt register to interrupt the application. When an interrupt bit is masked, the interrupt associated with that bit is not generated. However, the core interrupt (OTG\_GINTSTS) register bit corresponding to that interrupt is still set.

### 47.15.8 OTG receive status debug read register (OTG\_GRXSTSR)

Address offset for read: 0x01C

Reset value: 0x0000 0000

This description is for register OTG\_GRXSTSR in Device mode.

A read to the receive status debug read register returns the contents of the top of the receive FIFO.

The core ignores the receive status read when the receive FIFO is empty and returns a value of 0x0000 0000.

| 31      | 30         | 29   | 28   | 27          | 26   | 25   | 24          | 23 | 22 | 21 | 20          | 19 | 18 | 17 | 16      |

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **STSPHST**: Status phase start

Indicates the start of the status phase for a control write transfer. This bit is set along with the OUT transfer completed PKTSTS pattern.

Bits 26:25 Reserved, must be kept at reset value.

Bits 24:21 **FRMNUM[3:0]**: Frame number

This is the least significant 4 bits of the frame number in which the packet is received on the USB. This field is supported only when isochronous OUT endpoints are supported.

Bits 20:17 **PKTSTS[3:0]**: Packet status

Indicates the status of the received packet

0001: Global OUT NAK (triggers an interrupt)

0010: OUT data packet received

0011: OUT transfer completed (triggers an interrupt)

0100: SETUP transaction completed (triggers an interrupt)

0110: SETUP data packet received

Others: Reserved

Bits 16:15 **DPID[1:0]**: Data PID

Indicates the data PID of the received OUT data packet

00: DATA0

10: DATA1

Bits 14:4 **BCNT[10:0]**: Byte count

Indicates the byte count of the received data packet.

Bits 3:0 **EPNUM[3:0]**: Endpoint number

Indicates the endpoint number to which the current received packet belongs.

### 47.15.9 OTG receive status debug read [alternate] (OTG\_GRXSTSR)

Address offset for read: 0x01C

Reset value: 0x0000 0000

This description is for register OTG\_GRXSTSR in Host mode.

A read to the receive status debug read register returns the contents of the top of the receive FIFO.

The core ignores the receive status read when the receive FIFO is empty and returns a value of 0x0000 0000.

|      |            |      |      |      |      |      |      |      |      |      |             |    |    |    |      |

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:17 **PKTSTS[3:0]**: Packet status

Indicates the status of the received packet

0010: IN data packet received

0011: IN transfer completed (triggers an interrupt)

0101: Data toggle error (triggers an interrupt)

0111: Channel halted (triggers an interrupt)

Others: Reserved

Bits 16:15 **DPID[1:0]**: Data PID

Indicates the data PID of the received packet

00: DATA0

10: DATA1

Bits 14:4 **BCNT[10:0]**: Byte count

Indicates the byte count of the received IN data packet.

Bits 3:0 **CHNUM[3:0]**: Channel number

Indicates the channel number to which the current received packet belongs.

### 47.15.10 OTG status read and pop registers (OTG\_GRXSTSP)

Address offset for pop: 0x020

Reset value: 0x0000 0000

This description is for register OTG\_GRXSTSP in Device mode.

Similarly to OTG\_GRXSTSR (receive status debug read register) where a read returns the contents of the top of the receive FIFO, a read to OTG\_GRXSTSP (receive status read and pop register) additionally pops the top data entry out of the Rx FIFO.

The core ignores the receive status pop/read when the receive FIFO is empty and returns a value of 0x0000 0000. The application must only pop the receive status FIFO when the receive FIFO non-empty bit of the core interrupt register (RXFLVL bit in OTG\_GINTSTS) is asserted.

|         |            |      |      |             |      |      |             |    |    |    |             |    |    |    |         |

|         |            |      |      | r           |      |      | r           | r  | r  | r  | r           | r  | r  | r  | r       |
| 15      | 14         | 13   | 12   | 11          | 10   | 9    | 8           | 7  | 6  | 5  | 4           | 3  | 2  | 1  | 0       |
| DPID[0] | BCNT[10:0] |      |      |             |      |      |             |    |    |    | EPNUM[3:0]  |    |    |    |         |
| r       | r          | r    | r    | r           | r    | r    | r           | r  | r  | r  | r           | r  | r  | r  | r       |

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **STSPHST**: Status phase start

Indicates the start of the status phase for a control write transfer. This bit is set along with the OUT transfer completed PKTSTS pattern.

Bits 26:25 Reserved, must be kept at reset value.

Bits 24:21 **FRMNUM[3:0]**: Frame number

This is the least significant 4 bits of the frame number in which the packet is received on the USB. This field is supported only when isochronous OUT endpoints are supported.

Bits 20:17 **PKTSTS[3:0]**: Packet status

Indicates the status of the received packet

0001: Global OUT NAK (triggers an interrupt)

0010: OUT data packet received

0011: OUT transfer completed (triggers an interrupt)

0100: SETUP transaction completed (triggers an interrupt)

0110: SETUP data packet received

Others: Reserved

Bits 16:15 **DPID[1:0]**: Data PID

Indicates the data PID of the received OUT data packet

00: DATA0

10: DATA1

Bits 14:4 **BCNT[10:0]**: Byte count

Indicates the byte count of the received data packet.

Bits 3:0 **EPNUM[3:0]**: Endpoint number

Indicates the endpoint number to which the current received packet belongs.

### 47.15.11 OTG status read and pop registers [alternate] (OTG\_GRXSTSP)

Address offset for pop: 0x020

Reset value: 0x0000 0000

This description is for register OTG\_GRXSTSP in Host mode.

Similarly to OTG\_GRXSTSR (receive status debug read register) where a read returns the contents of the top of the receive FIFO, a read to OTG\_GRXSTSP (receive status read and pop register) additionally pops the top data entry out of the Rx FIFO.

The core ignores the receive status pop/read when the receive FIFO is empty and returns a value of 0x0000 0000. The application must only pop the receive status FIFO when the receive FIFO non-empty bit of the core interrupt register (RXFLVL bit in OTG\_GINTSTS) is asserted.

|      |            |      |      |      |      |      |      |      |      |      | r           | r  | r  | r  | r    |
| 15   | 14         | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4           | 3  | 2  | 1  | 0    |
| DPID | BCNT[10:0] |      |      |      |      |      |      |      |      |      | CHNUM[3:0]  |    |    |    |      |
| r    | r          | r    | r    | r    | r    | r    | r    | r    | r    | r    | r           | r  | r  | r  | r    |

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:17 **PKTSTS[3:0]**: Packet status

Indicates the status of the received packet

0010: IN data packet received

0011: IN transfer completed (triggers an interrupt)

0101: Data toggle error (triggers an interrupt)

0111: Channel halted (triggers an interrupt)

Others: Reserved

Bits 16:15 **DPID[1:0]**: Data PID

Indicates the data PID of the received packet

00: DATA0

10: DATA1

Bits 14:4 **BCNT[10:0]**: Byte count

Indicates the byte count of the received IN data packet.

Bits 3:0 **CHNUM[3:0]**: Channel number

Indicates the channel number to which the current received packet belongs.

### 47.15.12 OTG receive FIFO size register (OTG\_GRXFSIZ)

Address offset: 0x024

Reset value: 0x0000 0200

The application can program the RAM size that must be allocated to the Rx FIFO.

|            |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|------------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| 31         | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **RXFD[15:0]**: Rx FIFO depth

This value is in terms of 32-bit words.

Minimum value is 16

Programmed values must respect the available FIFO memory allocation and must not exceed the power-on value.

### 47.15.13 OTG host non-periodic transmit FIFO size register (OTG\_HNPTXFSIZ)/Endpoint 0 Transmit FIFO size (OTG\_DIEPTXF0)

Address offset: 0x028

Reset value: 0x0200 0200

|                      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

#### Host mode

Bits 31:16 **NPTXFD[15:0]**: Non-periodic Tx FIFO depth

This value is in terms of 32-bit words.

Minimum value is 16

Programmed values must respect the available FIFO memory allocation and must not exceed the power-on value.

Bits 15:0 **NPTXFSA[15:0]**: Non-periodic transmit RAM start address

This field configures the memory start address for non-periodic transmit FIFO RAM.

Device mode

- Bits 31:16 **TX0FD**: Endpoint 0 Tx FIFO depth  
 This value is in terms of 32-bit words.  
 Minimum value is 16  
 Programmed values must respect the available FIFO memory allocation and must not exceed the power-on value.
- Bits 15:0 **TX0FSA**: Endpoint 0 transmit RAM start address  
 This field configures the memory start address for the endpoint 0 transmit FIFO RAM.

47.15.14 OTG non-periodic transmit FIFO/queue status register (OTG\_HNPTXSTS)

Address offset: 0x02C  
 Reset value: 0x0008 0200

*Note:* In device mode, this register is not valid.

This read-only register contains the free space information for the non-periodic Tx FIFO and the non-periodic transmit request queue.

|                |               |    |    |    |    |    |    |               |    |    |    |    |    |    |    |
|----------------|---------------|----|----|----|----|----|----|---------------|----|----|----|----|----|----|----|
| 31             | 30            | 29 | 28 | 27 | 26 | 25 | 24 | 23            | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Res.           | NPTXQTOP[6:0] |    |    |    |    |    |    | NPTQXSAV[7:0] |    |    |    |    |    |    |    |
|                | r             | r  | r  | r  | r  | r  | r  | r             | r  | r  | r  | r  | r  | r  | r  |
| 15             | 14            | 13 | 12 | 11 | 10 | 9  | 8  | 7             | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| NPTXFSAV[15:0] |               |    |    |    |    |    |    |               |    |    |    |    |    |    |    |
| r              | r             | r  | r  | r  | r  | r  | r  | r             | r  | r  | r  | r  | r  | r  | r  |

Bit 31 Reserved, must be kept at reset value.

Bits 30:24 **NPTXQTOP[6:0]**: Top of the non-periodic transmit request queue

Entry in the non-periodic Tx request queue that is currently being processed by the MAC.

Bits 30:27: Channel/endpoint number

Bits 26:25:

00: IN/OUT token

01: Zero-length transmit packet (device IN/host OUT)

11: Channel halt command

Bit 24: Terminate (last entry for selected channel/endpoint)

Bits 23:16 **NPTQXSAV[7:0]**: Non-periodic transmit request queue space available

Indicates the amount of free space available in the non-periodic transmit request queue.

This queue holds both IN and OUT requests.

0: Non-periodic transmit request queue is full

1: 1 location available

2: locations available

n: n locations available ( $0 \leq n \leq 8$ )

Others: Reserved

Bits 15:0 **NPTXFSAV[15:0]**: Non-periodic Tx FIFO space available

Indicates the amount of free space available in the non-periodic Tx FIFO.

Values are in terms of 32-bit words.

0: Non-periodic Tx FIFO is full

1: 1 word available

2: 2 words available

n: n words available (where  $0 \leq n \leq 512$ )

Others: Reserved

#### 47.15.15 OTG general core configuration register (OTG\_GCCFG)

Address offset: 0x038

Reset value: 0x0000 XXXX

|      |      |      |      |      |      |      |      |      |      |       |      |        |       |       |        |

|      |      |      |      |      |      |      |      |      |      | rw    | rw   | rw     | rw    | rw    | rw     |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5     | 4    | 3      | 2     | 1     | 0      |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.  | Res. | PS2DET | SDET  | PDET  | DCDET  |
|      |      |      |      |      |      |      |      |      |      |       |      | r      | r     | r     | r      |

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 **VBDEN**: USB  $V_{BUS}$  detection enable

Enables  $V_{BUS}$  sensing comparators to detect  $V_{BUS}$  valid levels on the  $V_{BUS}$  PAD for USB host and device operation. If HNP and/or SRP support is enabled,  $V_{BUS}$  comparators are automatically enabled independently of VBDEN value.

0 =  $V_{BUS}$  detection disabled

1 =  $V_{BUS}$  detection enabled

Bit 20 **SDEN**: Secondary detection (SD) mode enable

This bit is set by the software to put the BCD into SD mode. Only one detection mode (DCD, PD, SD or OFF) must be selected to work correctly

Bit 19 **PDEN**: Primary detection (PD) mode enable

This bit is set by the software to put the BCD into PD mode. Only one detection mode (DCD, PD, SD or OFF) must be selected to work correctly.

Bit 18 **DCDEN**: Data contact detection (DCD) mode enable

This bit is set by the software to put the BCD into DCD mode. Only one detection mode (DCD, PD, SD or OFF) must be selected to work correctly.

Bit 17 **BCDEN**: Battery charging detector (BCD) enable

This bit is set by the software to enable the BCD support within the USB device. When enabled, the USB PHY is fully controlled by BCD and cannot be used for normal communication. Once the BCD discovery is finished, the BCD must be placed in OFF mode by clearing this bit to '0' in order to allow the normal USB operation.

Bit 16 **PWRDWN**: Power down control of FS PHY

Used to activate the FS PHY in transmission/reception. When reset, the PHY is kept in power-down. When set, the BCD function must be off (BCDEN=0).

0 = USB FS PHY disabled

1 = USB FS PHY enabled

Bits 15:4 Reserved, must be kept at reset value.

Bit 3 **PS2DET**: DM pull-up detection status

This bit is active only during PD and gives the result of comparison between DM voltage level and VLGC threshold. In normal situation, the DM level must be below this threshold. If it is above, it means that the DM is externally pulled high. This can be caused by connection to a PS2 port (which pulls-up both DP and DM lines) or to some proprietary charger not following the BCD specification.

0: Normal port detected (connected to SDP, CDP or DCP)

1: PS2 port or proprietary charger detected

Bit 2 **SDET**: Secondary detection (SD) status

This bit gives the result of SD.

0: CDP detected

1: DCP detected

Bit 1 **PDET**: Primary detection (PD) status

This bit gives the result of PD.

0: no BCD support detected (connected to SDP or proprietary device).

1: BCD support detected (connected to CDP or DCP).

Bit 0 **DCDET**: Data contact detection (DCD) status

This bit gives the result of DCD.

0: data lines contact not detected

1: data lines contact detected

### 47.15.16 OTG core ID register (OTG\_CID)

Address offset: 0x03C

Reset value: 0x0000 2000

This is a register containing the Product ID as reset value.

|                   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

| r          | r           | r    | rw         | rw              | rw | rw | rw         | rw           | rw          | rw        | rw            | rw | rw | rw         | rw          |

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **ENBESL**: Enable best effort service latency

This bit enables the BESL feature as defined in the LPM errata:

0: The core works as described in the following document:

*USB 2.0 Link Power Management Addendum Engineering Change Notice to the USB 2.0 specification, July 16, 2007*

1: The core works as described in the LPM Errata:

*Errata for USB 2.0 ECN: Link Power Management (LPM) - 7/2007*

*Note: Only the updated behavior (described in LPM Errata) is considered in this document and so the ENBESL bit must be set to '1' by application SW.*

Bits 27:25 **LPMRCNTSTS[2:0]**: LPM retry count status

Number of LPM host retries still remaining to be transmitted for the current LPM sequence.

*Note: Accessible only in host mode.*

Bit 24 **SNDLPM**: Send LPM transaction

When the application software sets this bit, an LPM transaction containing two tokens, EXT and LPM is sent. The hardware clears this bit once a valid response (STALL, NYET, or ACK) is received from the device or the core has finished transmitting the programmed number of LPM retries.

*Note: This bit must be set only when the host is connected to a local port.*

*Note: Accessible only in host mode.*

Bits 23:21 **LPMRCNT[2:0]**: LPM retry count

When the device gives an ERROR response, this is the number of additional LPM retries that the host performs until a valid device response (STALL, NYET, or ACK) is received.

*Note: Accessible only in host mode.*

Bits 20:17 **LPMCHIDX[3:0]**: LPM Channel Index

The channel number on which the LPM transaction has to be applied while sending an LPM transaction to the local device. Based on the LPM channel index, the core automatically inserts the device address and endpoint number programmed in the corresponding channel into the LPM transaction.

*Note: Accessible only in host mode.*

Bit 16 **L1RSMOK**: Sleep state resume OK

Indicates that the device or host can start resume from Sleep state. This bit is valid in LPM sleep (L1) state. It is set in sleep mode after a delay of 50  $\mu$ s ( $T_{L1Residency}$ ).

This bit is reset when SLPSTS is 0.

1: The application or host can start resume from Sleep state

0: The application or host cannot start resume from Sleep state

Bit 15 **SLPSTS**: Port sleep status

**Device mode:**

This bit is set as long as a Sleep condition is present on the USB bus. The core enters the Sleep state when an ACK response is sent to an LPM transaction and the  $T_{L1TokenRetry}$  timer has expired. To stop the PHY clock, the application must set the STPPCLK bit in OTG\_PCGCTL, which asserts the PHY suspend input signal.

The application must rely on SLPSTS and not ACK in LPMRSP to confirm transition into sleep.

The core comes out of sleep:

- When there is any activity on the USB line state
- When the application writes to the RWUSIG bit in OTG\_DCTL or when the application resets or soft-disconnects the device.

**Host mode:**

The host transitions to Sleep (L1) state as a side-effect of a successful LPM transaction by the core to the local port with ACK response from the device. The read value of this bit reflects the current Sleep status of the port.

The core clears this bit after:

- The core detects a remote L1 wake-up signal,
- The application sets the PRST bit or the PRES bit in the OTG\_HPRT register, or
- The application sets the L1Resume/ remote wake-up detected interrupt bit or disconnect detected interrupt bit in the core interrupt register (WKUPINT or DISCINT bit in OTG\_GINTSTS, respectively).

0: Core not in L1

1: Core in L1

Bits 14:13 **LPMRSP[1:0]**: LPM response

**Device mode:**

The response of the core to LPM transaction received is reflected in these two bits.

**Host mode:**

Handshake response received from local device for LPM transaction

11: ACK

10: NYET

01: STALL

00: ERROR (No handshake response)

Bit 12 **L1DSEN**: L1 deep sleep enable

Enables suspending the PHY in L1 Sleep mode. For maximum power saving during L1 Sleep mode, this bit must be set to '1' by application SW in all the cases.

Bits 11:8 **BESLTHRS[3:0]**: BESL threshold

**Device mode:**

The core puts the PHY into deep low power mode in L1 when BESL value is greater than or equal to the value defined in this field BESL\_Thres[3:0].

**Host mode:**

The core puts the PHY into deep low power mode in L1. BESLTHRS[3:0] specifies the time for which resume signaling is to be reflected by host ( $T_{L1HubDrvResume2}$ ) on the USB bus when it detects device initiated resume.

BESLTHRS must not be programmed with a value greater than 1100b in host mode, because this exceeds maximum  $T_{L1HubDrvResume2}$ .

Thres[3:0] host mode resume signaling time ( $\mu$ s):

0000: 75

0001: 100

0010: 150

0011: 250

0100: 350

0101: 450

0110: 950

All other values: reserved

Bit 7 **L1SSEN**: L1 Shallow Sleep enable

Enables suspending the PHY in L1 Sleep mode. For maximum power saving during L1 Sleep mode, this bit must be set to '1' by application SW in all the cases.

Bit 6 **REMWAKE**: bRemoteWake value

**Host mode:**

The value of remote wake up to be sent in the wIndex field of LPM transaction.

**Device mode (read-only):**

This field is updated with the received LPM token bRemoteWake bmAttribute when an ACK, NYET, or STALL response is sent to an LPM transaction.

Bits 5:2 **BESL[3:0]**: Best effort service latency

**Host mode:**

The value of BESL to be sent in an LPM transaction. This value is also used to initiate resume for a duration  $T_{L1HubDrvResume1}$  for host initiated resume.

**Device mode (read-only):**

This field is updated with the received LPM token BESL bmAttribute when an ACK, NYET, or STALL response is sent to an LPM transaction.

BESL[3:0] $T_{BESL}$  ( $\mu$ s)

0000: 125  
 0001: 150  
 0010: 200  
 0011: 300  
 0100: 400  
 0101: 500  
 0110: 1000  
 0111: 2000  
 1000: 3000  
 1001: 4000  
 1010: 5000  
 1011: 6000  
 1100: 7000  
 1101: 8000  
 1110: 9000  
 1111: 10000

Bit 1 **LPMACK**: LPM token acknowledge enable

Handshake response to LPM token preprogrammed by device application software.

1: ACK

Even though ACK is preprogrammed, the core device responds with ACK only on successful LPM transaction. The LPM transaction is successful if:

- No PID/CRC5 errors in either EXT token or LPM token (else ERROR)
- Valid bLinkState = 0001B (L1) received in LPM transaction (else STALL)
- No data pending in transmit queue (else NYET).

0: NYET

The preprogrammed software bit is over-ridden for response to LPM token when:

- The received bLinkState is not L1 (STALL response), or
- An error is detected in either of the LPM token packets because of corruption (ERROR response).

*Note: Accessible only in device mode.*

Bit 0 **LPMEN**: LPM support enable

The application uses this bit to control the OTG\_FS core LPM capabilities.

If the core operates as a non-LPM-capable host, it cannot request the connected device or hub to activate LPM mode.

If the core operates as a non-LPM-capable device, it cannot respond to any LPM transactions.

0: LPM capability is not enabled

1: LPM capability is enabled

### 47.15.18 OTG power down register (OTG\_GPWRDN)

Address offset: 0x058

Reset value: 0x0000 0010

|      |      |      |      |      |      |      |      |       |      |      |      |      |      |      |            |

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **ADPIF**: ADP interrupt flag

This bit is set whenever there is an ADP event

Bits 22:1 Reserved, must be kept at reset value.

Bit 0 **ADPMEN**: ADP module enable

This bit enables or disables the ADP logic.

0: Disable ADP module

1: Enable ADP module

### 47.15.19 OTG ADP timer, control and status register (OTG\_GADPCTL)

Address offset: 0x060

Reset value: 0x0000 0000

The OTG\_GADPCTL register must be accessed as follows:

- In order to read from the OTG\_GADPCTL register, program AR=0b01 and keep polling till AR=0b00. The core updates the other fields of this register and makes AR=0b00. Read values of this register are valid only when AR=0b00.
- In order to write to the OTG\_GADPCTL register, program AR=0b10 along with the values for the other fields and keep polling till AR=0b00. When AR becomes 0b00, it means that the programmed value has taken effect inside the core.

|      |      |      |    |    |             |              |              |             |              |              |       |            |            |            |      |

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:27 **AR**: Access request

This bitfield define the requested access mode to the OTG\_GADPCTL register:

00 Read / write valid (updated by the core)

01 Read request

10 Write request

11 Reserved

Bit 26 **ADPTOIM**: ADP timeout interrupt mask

When this bit is set, it unmask the interrupt from ADPTOIF.

Bit 25 **ADPSNSIM**: ADP sense interrupt mask

When this bit is set, it unmask the interrupt from ADPSNSIF.

Bit 24 **ADPPRBIM**: ADP probe interrupt mask

When this bit is set, it unmask the interrupt from ADPPRBIF.

Bit 23 **ADPTOIF**: ADP timeout interrupt flag

This bit is relevant only for an ADP probe. When this bit is set, it means that the ramp time has completed (RTIM has reached its terminal value of 0x7FF). This is a debug feature that allows the application to read the ramp time after each cycle.

Bit 22 **ADPSNSIF**: ADP sense interrupt flag

When this bit is set, it means that the  $V_{BUS}$  voltage is greater than  $V_{ADPSNS}$  value or that  $V_{ADPSNS}$  is reached.

Bit 21 **ADPPRBIF**: ADP probe interrupt flag

When this bit is set, it means that the  $V_{BUS}$  voltage is greater than  $V_{ADPPRB}$  or that  $V_{ADPPRB}$  is reached.

Bit 20 **ADPEN**: ADP enable

When set, the core performs either ADP probing or sensing based on ENAPRB or ENASNS.

Bit 19 **ADPRST**: ADP reset

When set, ADP controller is reset. This bit is auto-cleared after the reset procedure is complete in the ADP controller.

Bit 18 **ENASNS**: Enable sense

When programmed to 1, the core performs a sense operation.

Bit 17 **ENAPRB**: Enable probe

When programmed to 1, the core performs a probe operation.

Bits 16:6 **RTIM**: Ramp time

These bits capture the latest time it took for  $V_{BUS}$  to ramp from  $V_{ADPSINK}$  to  $V_{ADPPRB}$ . The bits are defined in units of 32 kHz clock cycles as follow:

000: 1 cycle

001: 2 cycles

002: 3 cycles

...

7FF: 2048 cycles

A time of 1024 cycles at 32 kHz corresponds to a time of 32 ms.

Bits 5:4 **PRBPER**: Probe period

These bits sets the  $T_{ADPPRD}$  as follow:  
 00: 0.625 to 0.925 sec (typical 0.775 sec)  
 01: 1.25 to 1.85 sec (typical 1.55 sec)  
 10: 1.9 to 2.6 sec (typical 2.275 sec)  
 11: Reserved

Bits 3:2 **PRBDELTA**: Probe delta

These bits set the resolution for RTIM value. The bits are defined in units of 32 kHz clock cycles as follow:  
 00: 1 cycle  
 01: 2 cycles  
 10: 3 cycles  
 11: 4 cycles  
 For example if this value is chosen to be 01, it means that RTIM increments for every two 32 kHz clock cycles.

Bits 1:0 **PRBDSCHG**: Probe discharge

These bits set the times for  $T_{ADP\_DSCHG}$ . These bits are defined as follow:  
 00: 4 ms  
 01: 8 ms  
 10: 16 ms  
 11: 32 ms

#### 47.15.20 OTG host periodic transmit FIFO size register (OTG\_HPTXFSIZ)

Address offset: 0x100

Reset value: 0x0200 0400

|               |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|---------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31            | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| PTXFSIZ[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW            | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |
| 15            | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| PTXSA[15:0]   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW            | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 31:16 **PTXFSIZ[15:0]**: Host periodic Tx FIFO depth

This value is in terms of 32-bit words.  
 Minimum value is 16

Bits 15:0 **PTXSA[15:0]**: Host periodic Tx FIFO start address

This field configures the memory start address for periodic transmit FIFO RAM.

### 47.15.21 OTG device IN endpoint transmit FIFO x size register (OTG\_DIEPTXFx)

Address offset:  $0x104 + 0x04 * (x - 1)$ , ( $x = 1$  to  $5$ )

Reset value: Block 1: 0x0200 0400

Reset value: Block 2: 0x0200 0600

Reset value: Block 3: 0x0200 0800

Reset value: Block 4: 0x0200 0A00

Reset value: Block 5: 0x0200 0C00

|                |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|----------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31             | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| INEPTXFD[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW             | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |
| 15             | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| INEPTXSA[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW             | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 31:16 **INEPTXFD[15:0]**: IN endpoint Tx FIFO depth

This value is in terms of 32-bit words.

Minimum value is 16

Bits 15:0 **INEPTXSA[15:0]**: IN endpoint FIFOx transmit RAM start address

This field contains the memory start address for IN endpoint transmit FIFOx. The address must be aligned with a 32-bit memory location.

### 47.15.22 Host-mode registers

Bit values in the register descriptions are expressed in binary unless otherwise specified.

Host-mode registers affect the operation of the core in the host mode. Host mode registers must not be accessed in device mode, as the results are undefined. Host mode registers can be categorized as follows:

### 47.15.23 OTG host configuration register (OTG\_HCFG)

Address offset: 0x400

Reset value: 0x0000 0000

This register configures the core after power-on. Do not make changes to this register after initializing the host.

|      |      |      |      |      |      |      |      |      |      |      |      |      |       |              |      |
|------|------|------|------|------|------|------|------|------|------|------|------|------|-------|--------------|------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18    | 17           | 16   |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. |      | Res. | Res. | Res. | Res. | Res. | Res.  | Res.         | Res. |
|      |      |      |      |      |      |      |      |      |      |      |      |      |       |              |      |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2     | 1            | 0    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | FSLSS | FSLSPCS[1:0] |      |
|      |      |      |      |      |      |      |      |      |      |      |      |      | r     | rW           | rW   |

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **FSLSS**: FS- and LS-only support

The application uses this bit to control the core's enumeration speed. Using this bit, the application can make the core enumerate as an FS host, even if the connected device supports HS traffic. Do not make changes to this field after initial programming.

1: FS/LS-only, even if the connected device can support HS (read-only).

Bits 1:0 **FSLSPCS[1:0]**: FS/LS PHY clock select

When the core is in FS host mode

01: PHY clock is running at 48 MHz

Others: Reserved

When the core is in LS host mode

00: Reserved

01: Select 48 MHz PHY clock frequency

10: Select 6 MHz PHY clock frequency

11: Reserved

*Note: The FSLSPCS must be set on a connection event according to the speed of the connected device (after changing this bit, a software reset must be performed).*

#### 47.15.24 OTG host frame interval register (OTG\_HFIR)

Address offset: 0x404

Reset value: 0x0000 EA60

This register stores the frame interval information for the current speed to which the OTG\_FS controller has enumerated.

|             |      |      |      |      |      |      |      |      |      |      |      |      |      |      |          |
|-------------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|----------|
| 31          | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16       |
| Res.        | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | RLD CTRL |
|             |      |      |      |      |      |      |      |      |      |      |      |      |      |      | rw       |
| 15          | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0        |
| FRIVL[15:0] |      |      |      |      |      |      |      |      |      |      |      |      |      |      |          |
| rw          | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw       |

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **RLDCTRL**: Reload control

This bit allows dynamic reloading of the HFIR register during run time.

0: The HFIR cannot be reloaded dynamically

1: The HFIR can be dynamically reloaded during run time.

This bit needs to be programmed during initial configuration and its value must not be changed during run time.

**Caution:** RLDCTRL = 0 is not recommended.

Bits 15:0 **FRIVL[15:0]**: Frame interval

The value that the application programs to this field, specifies the interval between two consecutive SOFs (FS) or Keep-Alive tokens (LS). This field contains the number of PHY clocks that constitute the required frame interval. The application can write a value to this register only after the port enable bit of the host port control and status register (PENA bit in OTG\_HPRT) has been set. If no value is programmed, the core calculates the value based on the PHY clock specified in the FS/LS PHY clock select field of the host configuration register (FSLSPCS in OTG\_HCFG). Do not change the value of this field after the initial configuration, unless the RLDCTRL bit is set. In such case, the FRIVL is reloaded with each SOF event.

– Frame interval = 1 ms × (FRIVL - 1)

#### 47.15.25 OTG host frame number/frame time remaining register (OTG\_HFNUM)

Address offset: 0x408

Reset value: 0x0000 3FFF

This register indicates the current frame number. It also indicates the time remaining (in terms of the number of PHY clocks) in the current frame.

|             |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31          | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| FTREM[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| r           | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  |
| 15          | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| FRNUM[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| r           | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  |

Bits 31:16 **FTREM[15:0]**: Frame time remaining

Indicates the amount of time remaining in the current frame, in terms of PHY clocks. This field decrements on each PHY clock. When it reaches zero, this field is reloaded with the value in the Frame interval register and a new SOF is transmitted on the USB.

Bits 15:0 **FRNUM[15:0]**: Frame number

This field increments when a new SOF is transmitted on the USB, and is cleared to 0 when it reaches 0x3FFF.

### 47.15.26 OTG\_Host periodic transmit FIFO/queue status register (OTG\_HPTXSTS)

Address offset: 0x410

Reset value: 0x0008 0100

This read-only register contains the free space information for the periodic Tx FIFO and the periodic transmit request queue.

|                |    |    |    |    |    |    |    |              |    |    |    |    |    |    |    |
|----------------|----|----|----|----|----|----|----|--------------|----|----|----|----|----|----|----|
| 31             | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23           | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| PTXQTOP[7:0]   |    |    |    |    |    |    |    | PTXQSAV[7:0] |    |    |    |    |    |    |    |
| r              | r  | r  | r  | r  | r  | r  | r  | r            | r  | r  | r  | r  | r  | r  | r  |
| 15             | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7            | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| PTXFSAVL[15:0] |    |    |    |    |    |    |    |              |    |    |    |    |    |    |    |
| r              | r  | r  | r  | r  | r  | r  | r  | r            | r  | r  | r  | r  | r  | r  | r  |

Bits 31:24 **PTXQTOP[7:0]**: Top of the periodic transmit request queue

This indicates the entry in the periodic Tx request queue that is currently being processed by the MAC.

This register is used for debugging.

Bit 31: Odd/Even frame

0: send in even frame

1: send in odd frame

Bits 30:27: Channel/endpoint number

Bits 26:25: Type

00: IN/OUT

01: Zero-length packet

11: Disable channel command

Bit 24: Terminate (last entry for the selected channel/endpoint)

Bits 23:16 **PTXQSAV[7:0]**: Periodic transmit request queue space available

Indicates the number of free locations available to be written in the periodic transmit request queue. This queue holds both IN and OUT requests.

00: Periodic transmit request queue is full

01: 1 location available

10: 2 locations available

bxn: n locations available ( $0 \leq n \leq 8$ )

Others: Reserved

Bits 15:0 **PTXFSAVL[15:0]**: Periodic transmit data FIFO space available

Indicates the number of free locations available to be written to in the periodic Tx FIFO.

Values are in terms of 32-bit words

0000: Periodic Tx FIFO is full

0001: 1 word available

0010: 2 words available

bxn: n words available (where  $0 \leq n \leq \text{PTXFD}$ )

Others: Reserved

### 47.15.27 OTG host all channels interrupt register (OTG\_HAINT)

Address offset: 0x414

Reset value: 0x0000 0000

When a significant event occurs on a channel, the host all channels interrupt register interrupts the application using the host channels interrupt bit of the core interrupt register (HCINT bit in OTG\_GINTSTS). This is shown in [Figure 540](#). There is one interrupt bit per channel, up to a maximum of 16 bits. Bits in this register are set and cleared when the application sets and clears bits in the corresponding host channel-x interrupt register.

|             |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |

| 15          | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| HAINT[15:0] |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| r           | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **HAINT[15:0]**: Channel interrupts

One bit per channel: Bit 0 for Channel 0, bit 15 for Channel 15

### 47.15.28 OTG host all channels interrupt mask register (OTG\_HAINTMSK)

Address offset: 0x418

Reset value: 0x0000 0000

The host all channel interrupt mask register works with the host all channel interrupt register to interrupt the application when an event occurs on a channel. There is one interrupt mask bit per channel, up to a maximum of 16 bits.

|              |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|--------------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **HAINTM[15:0]**: Channel interrupt mask

0: Masked interrupt

1: Unmasked interrupt

One bit per channel: Bit 0 for channel 0, bit 15 for channel 15

### 47.15.29 OTG host port control and status register (OTG\_HPRT)

Address offset: 0x440

Reset value: 0x0000 0000

This register is available only in host mode. Currently, the OTG host supports only one port.

A single register holds USB port-related information such as USB reset, enable, suspend, resume, connect status, and test mode for each port. It is shown in [Figure 540](#). The rc\_w1 bits in this register can trigger an interrupt to the application through the host port interrupt bit of the core interrupt register (HPRTINT bit in OTG\_GINTSTS). On a port interrupt, the application must read this register and clear the bit that caused the interrupt. For the rc\_w1 bits, the application must write a 1 to the bit to clear the interrupt.

|            |      |      |      |            |      |      |      |       |      |          |      |          |           |       |          |
|------------|------|------|------|------------|------|------|------|-------|------|----------|------|----------|-----------|-------|----------|

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:17 **PSPD[1:0]**: Port speed

Indicates the speed of the device attached to this port.

01: Full speed

10: Low speed

11: Reserved

Bits 16:13 **PTCTL[3:0]**: Port test control

The application writes a nonzero value to this field to put the port into a Test mode, and the corresponding pattern is signaled on the port.

0000: Test mode disabled

0001: Test\_J mode

0010: Test\_K mode

0011: Test\_SE0\_NAK mode

0100: Test\_Packet mode

0101: Test\_Force\_Enable

Others: Reserved

Bit 12 **PPWR**: Port power

The application uses this field to control power to this port, and the core clears this bit on an overcurrent condition.

0: Power off

1: Power on

Bits 11:10 **PLSTS[1:0]**: Port line status

Indicates the current logic level USB data lines

Bit 10: Logic level of OTG\_DP

Bit 11: Logic level of OTG\_DM

Bit 9 Reserved, must be kept at reset value.

**Bit 8 PRST:** Port reset

When the application sets this bit, a reset sequence is started on this port. The application must time the reset period and clear this bit after the reset sequence is complete.

0: Port not in reset

1: Port in reset

The application must leave this bit set for a minimum duration of at least 10 ms to start a reset on the port. The application can leave it set for another 10 ms in addition to the required minimum duration, before clearing the bit, even though there is no maximum limit set by the USB standard.

High speed: 50 ms

Full speed/Low speed: 10 ms

**Bit 7 PSUSP:** Port suspend

The application sets this bit to put this port in suspend mode. The core only stops sending SOFs when this is set. To stop the PHY clock, the application must set the port clock stop bit, which asserts the suspend input pin of the PHY.

The read value of this bit reflects the current suspend status of the port. This bit is cleared by the core after a remote wake-up signal is detected or the application sets the port reset bit or port resume bit in this register or the resume/remote wake-up detected interrupt bit or disconnect detected interrupt bit in the core interrupt register (WKUPINT or DISCINT in OTG\_GINTSTS, respectively).

0: Port not in suspend mode

1: Port in suspend mode

**Bit 6 PRES:** Port resume

The application sets this bit to drive resume signaling on the port. The core continues to drive the resume signal until the application clears this bit.

If the core detects a USB remote wake-up sequence, as indicated by the port resume/remote wake-up detected interrupt bit of the core interrupt register (WKUPINT bit in OTG\_GINTSTS), the core starts driving resume signaling without application intervention and clears this bit when it detects a disconnect condition. The read value of this bit indicates whether the core is currently driving resume signaling.

0: No resume driven

1: Resume driven

When LPM is enabled and the core is in L1 state, the behavior of this bit is as follow:

1. The application sets this bit to drive resume signaling on the port.

2. The core continues to drive the resume signal until a predetermined time specified in BESLTHRS[3:0] field of OTG\_GLPMCFG register.

3. If the core detects a USB remote wake-up sequence, as indicated by the port L1Resume/Remote L1Wakeup detected interrupt bit of the core interrupt register (WKUPINT in OTG\_GINTSTS), the core starts driving resume signaling without application intervention and clears this bit at the end of resume. This bit can be set or cleared by both the core and the application. This bit is cleared by the core even if there is no device connected to the host.

**Bit 5 POCCHNG:** Port overcurrent change

The core sets this bit when the status of the port overcurrent active bit (bit 4) in this register changes.

**Bit 4 POCA:** Port overcurrent active

Indicates the overcurrent condition of the port.

0: No overcurrent condition

1: Overcurrent condition

**Bit 3 PENCHNG:** Port enable/disable change

The core sets this bit when the status of the port enable bit 2 in this register changes.

Bit 2 **PENA**: Port enable

A port is enabled only by the core after a reset sequence, and is disabled by an overcurrent condition, a disconnect condition, or by the application clearing this bit. The application cannot set this bit by a register write. It can only clear it to disable the port. This bit does not trigger any interrupt to the application.

0: Port disabled

1: Port enabled

Bit 1 **PCDET**: Port connect detected

The core sets this bit when a device connection is detected to trigger an interrupt to the application using the host port interrupt bit in the core interrupt register (HPRTINT bit in OTG\_GINTSTS). The application must write a 1 to this bit to clear the interrupt.

Bit 0 **PCSTS**: Port connect status

0: No device is attached to the port

1: A device is attached to the port

**47.15.30 OTG host channel x characteristics register (OTG\_HCCHARx)**

Address offset:  $0x500 + 0x20 * x$ , ( $x = 0$  to  $11$ )

Reset value: 0x0000 0000

| 31    | 30         | 29      | 28       | 27 | 26          | 25 | 24 | 23 | 22        | 21 | 20         | 19 | 18    | 17   | 16 |

Bit 31 **CHENA**: Channel enable

This field is set by the application and cleared by the OTG host.

0: Channel disabled

1: Channel enabled

Bit 30 **CHDIS**: Channel disable

The application sets this bit to stop transmitting/receiving data on a channel, even before the transfer for that channel is complete. The application must wait for the Channel disabled interrupt before treating the channel as disabled.

Bit 29 **ODDFRM**: Odd frame

This field is set (reset) by the application to indicate that the OTG host must perform a transfer in an odd frame. This field is applicable for only periodic (isochronous and interrupt) transactions.

0: Even frame

1: Odd frame

Bits 28:22 **DAD[6:0]**: Device address

This field selects the specific device serving as the data source or sink.

Bits 21:20 **MCNT[1:0]**: Multicount

This field indicates to the host the number of transactions that must be executed per frame for this periodic endpoint. For non-periodic transfers, this field is not used

00: Reserved. This field yields undefined results

01: 1 transaction

10: 2 transactions per frame to be issued for this endpoint

11: 3 transactions per frame to be issued for this endpoint

*Note: This field must be set to at least 01.*

Bits 19:18 **EPTYP[1:0]**: Endpoint type

Indicates the transfer type selected.

00: Control

01: Isochronous

10: Bulk

11: Interrupt

Bit 17 **LSDEV**: Low-speed device

This field is set by the application to indicate that this channel is communicating to a low-speed device.

Bit 16 Reserved, must be kept at reset value.

Bit 15 **EPDIR**: Endpoint direction

Indicates whether the transaction is IN or OUT.

0: OUT

1: IN

Bits 14:11 **EPNUM[3:0]**: Endpoint number

Indicates the endpoint number on the device serving as the data source or sink.

Bits 10:0 **MPSIZ[10:0]**: Maximum packet size

Indicates the maximum packet size of the associated endpoint.

### 47.15.31 OTG host channel x interrupt register (OTG\_HCINTx)

Address offset:  $0x508 + 0x20 * x$ , ( $x = 0$  to 11)

Reset value: 0x0000 0000

This register indicates the status of a channel with respect to USB- and AHB-related events. It is shown in [Figure 540](#). The application must read this register when the host channels interrupt bit in the core interrupt register (HCINT bit in OTG\_GINTSTS) is set. Before the application can read this register, it must first read the host all channels interrupt (OTG\_HAINT) register to get the exact channel number for the host channel-x interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the OTG\_HAINT and OTG\_GINTSTS registers.

|      |      |      |      |      |       |        |       |       |      |       |       |       |      |       |       |

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **DTERR**: Data toggle error.

Bit 9 **FRMOR**: Frame overrun.

Bit 8 **BBERR**: Babble error.

Bit 7 **TXERR**: Transaction error.

Indicates one of the following errors occurred on the USB.

CRC check failure

Timeout

Bit stuff error

False EOP

Bit 6 Reserved, must be kept at reset value.

Bit 5 **ACK**: ACK response received/transmitted interrupt.

Bit 4 **NAK**: NAK response received interrupt.

Bit 3 **STALL**: STALL response received interrupt.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **CHH**: Channel halted

This indicates that the transfer completed:

– because of any USB transaction error

– in response to disable request by the application

– normally

Bit 0 **XFRC**: Transfer completed.

Transfer completed normally without any errors.

### 47.15.32 OTG host channel x interrupt mask register (OTG\_HCINTMSKx)

Address offset:  $0x50C + 0x20 * x$ , ( $x = 0$  to 11)

Reset value: 0x0000 0000

This register reflects the mask for each channel status described in the previous section.

| 31   | 30   | 29   | 28   | 27   | 26         | 25         | 24         | 23         | 22   | 21   | 20   | 19         | 18   | 17   | 16        |

**Bit 31 DOPNG:** Do Ping

This bit is used only for OUT transfers. Setting this field to 1 directs the host to do PING protocol.

*Note: Do not set this bit for IN transfers. If this bit is set for IN transfers, it disables the channel.*

**Bits 30:29 DPID[1:0]:** Data PID

The application programs this field with the type of PID to use for the initial transaction. The host maintains this field for the rest of the transfer.

00: DATA0

10: DATA1

11: SETUP (control) / reserved (non-control)

**Bits 28:19 PKTCNT[9:0]:** Packet count

This field is programmed by the application with the expected number of packets to be transmitted (OUT) or received (IN).

The host decrements this count on every successful transmission or reception of an OUT/IN packet. Once this count reaches zero, the application is interrupted to indicate normal completion.

**Bits 18:0 XFRSIZ[18:0]:** Transfer size

For an OUT, this field is the number of data bytes the host sends during the transfer.

For an IN, this field is the buffer size that the application has reserved for the transfer. The application is expected to program this field as an integer multiple of the maximum packet size for IN transactions (periodic and non-periodic).

**47.15.34 Device-mode registers**

These registers must be programmed every time the core changes to device mode

**47.15.35 OTG device configuration register (OTG\_DCFG)**

Address offset: 0x800

Reset value: 0x0220 0000

This register configures the core in device mode after power-on or after certain control commands or enumeration. Do not make changes to this register after initial programming.

|             |      |      |            |      |          |      |      |      |      |      |      |              |           |      |      |
|-------------|------|------|------------|------|----------|------|------|------|------|------|------|--------------|-----------|------|------|

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **ERRATIM**: Erratic error interrupt mask

1: Mask early suspend interrupt on erratic error

0: Early suspend interrupt is generated on erratic error

*Note: This bit is available in STM32L49x/L4Ax products, reserved otherwise.*

Bit 14 Reserved, must be kept at reset value.

Bit 13 Reserved, must be kept at reset value.

Bits 12:11 **PFIVL[1:0]**: Periodic frame interval

Indicates the time within a frame at which the application must be notified using the end of periodic frame interrupt. This can be used to determine if all the isochronous traffic for that frame is complete.

00: 80% of the frame interval

01: 85% of the frame interval

10: 90% of the frame interval

11: 95% of the frame interval

Bits 10:4 **DAD[6:0]**: Device address

The application must program this field after every SetAddress control command.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **NZLSOHSK**: Non-zero-length status OUT handshake

The application can use this field to select the handshake the core sends on receiving a nonzero-length data packet during the OUT transaction of a control transfer's status stage.

1: Send a STALL handshake on a nonzero-length status OUT transaction and do not send the received OUT packet to the application.

0: Send the received OUT packet to the application (zero-length or nonzero-length) and send a handshake based on the NAK and STALL bits for the endpoint in the device endpoint control register.

Bits 1:0 **DSPD[1:0]**: Device speed

Indicates the speed at which the application requires the core to enumerate, or the maximum speed the application can support. However, the actual bus speed is determined only after the chirp sequence is completed, and is based on the speed of the USB host to which the core is connected.

00: Reserved

01: Reserved

10: Reserved

11: Full speed (USB 1.1 transceiver clock is 48 MHz)

### 47.15.36 OTG device control register (OTG\_DCTL)

Address offset: 0x804

Reset value: 0x0000 0002

|      |      |      |      |                  |            |            |            |            |           |      |      |            |                    |      |            |

Bits 31:19 Reserved, must be kept at reset value.

Bit 18 **DSBESLRJCT**: Deep sleep BESL reject

Core rejects LPM request with BESL value greater than BESL threshold programmed. NYET response is sent for LPM tokens with BESL value greater than BESL threshold. By default, the deep sleep BESL reject feature is disabled.

Bits 17:12 Reserved, must be kept at reset value.

Bit 11 **POPRGDNE**: Power-on programming done

The application uses this bit to indicate that register programming is completed after a wake-up from power down mode.

Bit 10 **CGONAK**: Clear global OUT NAK

Writing 1 to this field clears the Global OUT NAK.

Bit 9 **SGONAK**: Set global OUT NAK

Writing 1 to this field sets the Global OUT NAK.

The application uses this bit to send a NAK handshake on all OUT endpoints.

The application must set the this bit only after making sure that the Global OUT NAK effective bit in the core interrupt register (GONAKEFF bit in OTG\_GINTSTS) is cleared.

Bit 8 **CGINAK**: Clear global IN NAK

Writing 1 to this field clears the Global IN NAK.

Bit 7 **SGINAK**: Set global IN NAK

Writing 1 to this field sets the Global non-periodic IN NAK. The application uses this bit to send a NAK handshake on all non-periodic IN endpoints.

The application must set this bit only after making sure that the Global IN NAK effective bit in the core interrupt register (GINAKEFF bit in OTG\_GINTSTS) is cleared.

Bits 6:4 **TCTL[2:0]**: Test control

000: Test mode disabled

001: Test\_J mode

010: Test\_K mode

011: Test\_SE0\_NAK mode

100: Test\_Packet mode

101: Test\_Force\_Enable

Others: Reserved

**Bit 3 GONSTS:** Global OUT NAK status

0: A handshake is sent based on the FIFO status and the NAK and STALL bit settings.

1: No data is written to the Rx FIFO, irrespective of space availability. Sends a NAK handshake on all packets, except on SETUP transactions. All isochronous OUT packets are dropped.

**Bit 2 GINSTS:** Global IN NAK status

0: A handshake is sent out based on the data availability in the transmit FIFO.

1: A NAK handshake is sent out on all non-periodic IN endpoints, irrespective of the data availability in the transmit FIFO.

**Bit 1 SDIS:** Soft disconnect

The application uses this bit to signal the USB OTG core to perform a soft disconnect. As long as this bit is set, the host does not see that the device is connected, and the device does not receive signals on the USB. The core stays in the disconnected state until the application clears this bit.

0: Normal operation. When this bit is cleared after a soft disconnect, the core generates a device connect event to the USB host. When the device is reconnected, the USB host restarts device enumeration.

1: The core generates a device disconnect event to the USB host.

**Bit 0 RWUSIG:** Remote wake-up signaling

When the application sets this bit, the core initiates remote signaling to wake up the USB host. The application must set this bit to instruct the core to exit the suspend state. As specified in the USB 2.0 specification, the application must clear this bit 1 ms to 15 ms after setting it.

If LPM is enabled and the core is in the L1 (sleep) state, when the application sets this bit, the core initiates L1 remote signaling to wake up the USB host. The application must set this bit to instruct the core to exit the sleep state. As specified in the LPM specification, the hardware automatically clears this bit 50  $\mu$ s ( $T_{L1DevDrvResume}$ ) after being set by the application. The application must not set this bit when bRemoteWake from the previous LPM transaction is zero (refer to REMWAKE bit in GLPMCFG register).

**Table 328** contains the minimum duration (according to device state) for which the Soft disconnect (SDIS) bit must be set for the USB host to detect a device disconnect. To accommodate clock jitter, it is recommended that the application add some extra delay to the specified minimum duration.

**Table 328. Minimum duration for soft disconnect**

| Operating speed | Device state                                    | Minimum duration   |
|-----------------|-------------------------------------------------|--------------------|
| Full speed      | Suspended                                       | 1 ms + 2.5 $\mu$ s |
| Full speed      | Idle                                            | 2.5 $\mu$ s        |
| Full speed      | Not Idle or suspended (Performing transactions) | 2.5 $\mu$ s        |

### 47.15.37 OTG device status register (OTG\_DSTS)

Address offset: 0x808

Reset value: 0x0000 0010

This register indicates the status of the core with respect to USB-related events. It must be read on interrupts from the device all interrupts (OTG\_DAINTE) register.

|            |      |      |      |      |      |      |      |               |      |             |      |      |              |    |         |
|------------|------|------|------|------|------|------|------|---------------|------|-------------|------|------|--------------|----|---------|
| 31         | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23            | 22   | 21          | 20   | 19   | 18           | 17 | 16      |

|            |      |      |      |      |      |      |      | r             | r    | r           | r    | r    | r            | r  | r       |
| 15         | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7             | 6    | 5           | 4    | 3    | 2            | 1  | 0       |
| FNSOF[7:0] |      |      |      |      |      |      |      | Res.          | Res. | Res.        | Res. | EERR | ENUMSPD[1:0] |    | SUSPSTS |
| r          | r    | r    | r    | r    | r    | r    | r    |               |      |             |      | r    | r            | r  | r       |

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:22 **DEVLNSTS[1:0]**: Device line status

Indicates the current logic level USB data lines.

Bit [23]: Logic level of D+

Bit [22]: Logic level of D-

Bits 21:8 **FNSOF[13:0]**: Frame number of the received SOF

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **EERR**: Erratic error

The core sets this bit to report any erratic errors.

Due to erratic errors, the OTG\_FS controller goes into suspended state and an interrupt is generated to the application with Early suspend bit of the OTG\_GINTSTS register (ESUSP bit in OTG\_GINTSTS). If the early suspend is asserted due to an erratic error, the application can only perform a soft disconnect recover.

Bits 2:1 **ENUMSPD[1:0]**: Enumerated speed

Indicates the speed at which the OTG\_FS controller has come up after speed detection through a chirp sequence.

11: Full speed using embedded FS PHY

Others: reserved

Bit 0 **SUSPSTS**: Suspend status

In device mode, this bit is set as long as a suspend condition is detected on the USB. The core enters the suspended state when there is no activity on the USB data lines for a period of 3 ms. The core comes out of the suspend:

- When there is an activity on the USB data lines
- When the application writes to the remote wake-up signaling bit in the OTG\_DCTL register (RWUSIG bit in OTG\_DCTL).

### 47.15.38 OTG device IN endpoint common interrupt mask register (OTG\_DIEPMSK)

Address offset: 0x810

Reset value: 0x0000 0000

This register works with each of the OTG\_DIEPINTx registers for all endpoints to generate an interrupt per IN endpoint. The IN endpoint interrupt for a specific status in the OTG\_DIEPINTx register can be masked by writing to the corresponding bit in this register. Status bits are masked by default.

|      |      |      |      |      |      |      |      |      |             |             |               |      |      |      |           |

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **NAKM**: NAK interrupt mask

0: Masked interrupt

1: Unmasked interrupt

Bits 12:10 Reserved, must be kept at reset value.

Bit 9 Reserved, must be kept at reset value.

Bit 8 Reserved, must be kept at reset value.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **INEPNEM**: IN endpoint NAK effective mask

0: Masked interrupt

1: Unmasked interrupt

Bit 5 **INEPNMM**: IN token received with EP mismatch mask

0: Masked interrupt

1: Unmasked interrupt

Bit 4 **ITTXFEMSK**: IN token received when Tx FIFO empty mask

0: Masked interrupt

1: Unmasked interrupt

Bit 3 **TOM**: Timeout condition mask (Non-isochronous endpoints)

0: Masked interrupt

1: Unmasked interrupt

Bit 2 Reserved, must be kept at reset value.

Bit 1 **EPDM**: Endpoint disabled interrupt mask

0: Masked interrupt

1: Unmasked interrupt

Bit 0 **XFRCM**: Transfer completed interrupt mask

0: Masked interrupt

1: Unmasked interrupt

### 47.15.39 OTG device OUT endpoint common interrupt mask register (OTG\_DOEPMSK)

Address offset: 0x814

Reset value: 0x0000 0000

This register works with each of the OTG\_DOEPINTx registers for all endpoints to generate an interrupt per OUT endpoint. The OUT endpoint interrupt for a specific status in the OTG\_DOEPINTx register can be masked by writing into the corresponding bit in this register. Status bits are masked by default.

Bit 7 Reserved, must be kept at reset value.

Bit 6 Reserved, must be kept at reset value.

Bit 5 **STSPHSRXM**: Status phase received for control write mask

0: Masked interrupt

1: Unmasked interrupt

Bit 4 **OTEPDM**: OUT token received when endpoint disabled mask. Applies to control OUT endpoints only.

- 0: Masked interrupt
- 1: Unmasked interrupt

Bit 3 **STUPM**: STUPM: SETUP phase done mask. Applies to control endpoints only.

- 0: Masked interrupt
- 1: Unmasked interrupt

Bit 2 Reserved, must be kept at reset value.

Bit 1 **EPDM**: Endpoint disabled interrupt mask

- 0: Masked interrupt
- 1: Unmasked interrupt

Bit 0 **XFRM**: Transfer completed interrupt mask

- 0: Masked interrupt
- 1: Unmasked interrupt

#### 47.15.40 OTG device all endpoints interrupt register (OTG\_DAINR)

Address offset: 0x818

Reset value: 0x0000 0000

When a significant event occurs on an endpoint, a OTG\_DAINR register interrupts the application using the device OUT endpoints interrupt bit or device IN endpoints interrupt bit of the OTG\_GINTSTS register (OEPINT or IEPINT in OTG\_GINTSTS, respectively). There is one interrupt bit per endpoint, up to a maximum of 16 bits for OUT endpoints and 16 bits for IN endpoints. For a bidirectional endpoint, the corresponding IN and OUT interrupt bits are used. Bits in this register are set and cleared when the application sets and clears bits in the corresponding device endpoint-x interrupt register (OTG\_DIEPINTx/OTG\_DOEPINTx).

|              |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|--------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31           | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| OEPINT[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| r            | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  |
| 15           | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| IEPINT[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| r            | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  |

Bits 31:16 **OEPINT[15:0]**: OUT endpoint interrupt bits

One bit per OUT endpoint:

Bit 16 for OUT endpoint 0, bit 19 for OUT endpoint 3.

Bits 15:0 **IEPINT[15:0]**: IN endpoint interrupt bits

One bit per IN endpoint:

Bit 0 for IN endpoint 0, bit 3 for endpoint 3.

#### 47.15.41 OTG all endpoints interrupt mask register (OTG\_DAINTRMSK)

Address offset: 0x81C

Reset value: 0x0000 0000

The OTG\_DAINTRMSK register works with the device endpoint interrupt register to interrupt the application when an event occurs on a device endpoint. However, the OTG\_DAINTR register bit corresponding to that interrupt is still set.

|            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

| rW         | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 31:16 **OEPM[15:0]**: OUT EP interrupt mask bits

One per OUT endpoint:

Bit 16 for OUT EP 0, bit 19 for OUT EP 3

0: Masked interrupt

1: Unmasked interrupt

Bits 15:0 **IEPM[15:0]**: IN EP interrupt mask bits

One bit per IN endpoint:

Bit 0 for IN EP 0, bit 3 for IN EP 3

0: Masked interrupt

1: Unmasked interrupt

#### 47.15.42 OTG device V<sub>BUS</sub> discharge time register (OTG\_DVBUSDIS)

Address offset: 0x0828

Reset value: 0x0000 17D7

This register specifies the V<sub>BUS</sub> discharge time after V<sub>BUS</sub> pulsing during SRP.

|              |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |

| 15           | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| VBUSDT[15:0] |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| rW           | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **VBUSDT[15:0]**: Device  $V_{BUS}$  discharge time

Specifies the  $V_{BUS}$  discharge time after  $V_{BUS}$  pulsing during SRP. This value equals:

$V_{BUS}$  discharge time in PHY clocks / 1 024

Depending on  $V_{BUS}$  load, this value may need adjusting.

#### 47.15.43 OTG device $V_{BUS}$ pulsing time register (OTG\_DVBUSPULSE)

Address offset: 0x082C

Reset value: 0x0000 05B8

This register specifies the  $V_{BUS}$  pulsing time during SRP.

|              |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|--------------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| 31           | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |

|              |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| 15           | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| DVBUSP[15:0] |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| r/w          | r/w  | r/w  | r/w  | r/w  | r/w  | r/w  | r/w  | r/w  | r/w  | r/w  | r/w  | r/w  | r/w  | r/w  | r/w  |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **DVBUSP[15:0]**: Device  $V_{BUS}$  pulsing time. This feature is only relevant to OTG1.3.

Specifies the  $V_{BUS}$  pulsing time during SRP. This value equals:

$V_{BUS}$  pulsing time in PHY clocks / 1 024

#### 47.15.44 OTG device IN endpoint FIFO empty interrupt mask register (OTG\_DIEPEMPMSK)

Address offset: 0x834

Reset value: 0x0000 0000

This register is used to control the IN endpoint FIFO empty interrupt generation (TXFE\_OTG\_DIEPINTx).

|                 |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|-----------------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|

|                 |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| 15              | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| INEPTXFEM[15:0] |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| r/w             | r/w  | r/w  | r/w  | r/w  | r/w  | r/w  | r/w  | r/w  | r/w  | r/w  | r/w  | r/w  | r/w  | r/w  | r/w  |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **INEPTXFEM[15:0]**: IN EP Tx FIFO empty interrupt mask bits

These bits act as mask bits for OTG\_DIEPINTx.

TXFE interrupt one bit per IN endpoint:

Bit 0 for IN endpoint 0, bit 3 for IN endpoint 3

0: Masked interrupt

1: Unmasked interrupt

#### 47.15.45 OTG device control IN endpoint 0 control register (OTG\_DIEPCTL0)

Address offset: 0x900

Reset value: 0x0000 0000

This section describes the OTG\_DIEPCTL0 register for USB\_OTG FS. Nonzero control endpoints use registers for endpoints 1–3.

|         |       |      |      |      |      |             |      |      |      |       |      |            |      |            |      |
|---------|-------|------|------|------|------|-------------|------|------|------|-------|------|------------|------|------------|------|

| USBA EP | Res.  | Res. | Res. | Res. | Res. | Res.        | Res. | Res. | Res. | Res.  | Res. | Res.       | Res. | MPSIZ[1:0] |      |
| r       |       |      |      |      |      |             |      |      |      |       |      |            |      | rw         | rw   |

Bit 31 **EPENA**: Endpoint enable

The application sets this bit to start transmitting data on the endpoint 0.

The core clears this bit before setting any of the following interrupts on this endpoint:

- Endpoint disabled
- Transfer completed

Bit 30 **EPDIS**: Endpoint disable

The application sets this bit to stop transmitting data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the endpoint disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the endpoint disabled interrupt. The application must set this bit only if endpoint enable is already set for this endpoint.

Bits 29:28 Reserved, must be kept at reset value.

Bit 27 **SNAK**: Set NAK

A write to this bit sets the NAK bit for the endpoint.

Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also set this bit for an endpoint after a SETUP packet is received on that endpoint.

Bit 26 **CNAK**: Clear NAK

A write to this bit clears the NAK bit for the endpoint.

Bits 25:22 **TXFNUM[3:0]**: Tx FIFO number

This value is set to the FIFO number that is assigned to IN endpoint 0.

Bit 21 **STALL**: STALL handshake

The application can only set this bit, and the core clears it when a SETUP token is received for this endpoint. If a NAK bit, a Global IN NAK or Global OUT NAK is set along with this bit, the STALL bit takes priority.

Bit 20 Reserved, must be kept at reset value.

Bits 19:18 **EPTYP[1:0]**: Endpoint type

Hardcoded to '00' for control.

Bit 17 **NAKSTS**: NAK status

Indicates the following:

0: The core is transmitting non-NAK handshakes based on the FIFO status

1: The core is transmitting NAK handshakes on this endpoint.

When this bit is set, either by the application or core, the core stops transmitting data, even if there are data available in the Tx FIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake.

Bit 16 Reserved, must be kept at reset value.

Bit 15 **USBAEP**: USB active endpoint

This bit is always set to 1, indicating that control endpoint 0 is always active in all configurations and interfaces.

Bits 14:2 Reserved, must be kept at reset value.

Bits 1:0 **MPSIZ[1:0]**: Maximum packet size

The application must program this field with the maximum packet size for the current logical endpoint.

00: 64 bytes

01: 32 bytes

10: 16 bytes

11: 8 bytes

#### 47.15.46 OTG device IN endpoint x control register (OTG\_DIEPCTLx)

Address offset:  $0x900 + 0x20 * x$ , ( $x = 1$  to  $5$ )

Reset value: 0x0000 0000

The application uses this register to control the behavior of each logical endpoint other than endpoint 0.

- Bit 31 **EPENA**: Endpoint enable  
 The application sets this bit to start transmitting data on an endpoint.  
 The core clears this bit before setting any of the following interrupts on this endpoint:
- SETUP phase done
  - Endpoint disabled
  - Transfer completed
- Bit 30 **EPDIS**: Endpoint disable  
 The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the endpoint disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the endpoint disabled interrupt. The application must set this bit only if endpoint enable is already set for this endpoint.
- Bit 29 **SODDFRM**: Set odd frame  
 Applies to isochronous IN and OUT endpoints only.  
 Writing to this field sets the Even/Odd frame (EONUM) field to odd frame.
- Bit 28 **SD0PID**: Set DATA0 PID  
 Applies to interrupt/bulk IN endpoints only.  
 Writing to this field sets the endpoint data PID (DPID) field in this register to DATA0.
- SEVNFRM**: Set even frame  
 Applies to isochronous IN endpoints only.  
 Writing to this field sets the Even/Odd frame (EONUM) field to even frame.
- Bit 27 **SNAK**: Set NAK  
 A write to this bit sets the NAK bit for the endpoint.  
 Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also set this bit for OUT endpoints on a transfer completed interrupt, or after a SETUP is received on the endpoint.
- Bit 26 **CNAK**: Clear NAK  
 A write to this bit clears the NAK bit for the endpoint.
- Bits 25:22 **TXFNUM[3:0]**: Tx FIFO number  
 These bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number.  
 This field is valid only for IN endpoints.
- Bit 21 **STALL**: STALL handshake  
 Applies to non-control, non-isochronous IN endpoints only (access type is rw).  
 The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core.
- Bit 20 Reserved, must be kept at reset value.
- Bits 19:18 **EPTYP[1:0]**: Endpoint type  
 This is the transfer type supported by this logical endpoint.
- 00: Control
  - 01: Isochronous
  - 10: Bulk
  - 11: Interrupt

**Bit 17 NAKSTS:** NAK status

It indicates the following:

0: The core is transmitting non-NAK handshakes based on the FIFO status.

1: The core is transmitting NAK handshakes on this endpoint.

When either the application or the core sets this bit:

For non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there are data available in the Tx FIFO.

For isochronous IN endpoints: The core sends out a zero-length data packet, even if there are data available in the Tx FIFO.

Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake.

**Bit 16 EONUM:** Even/odd frame

Applies to isochronous IN endpoints only.

Indicates the frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd frame number in which it intends to transmit/receive isochronous data for this endpoint using the SEVNFRM and SODDFRM fields in this register.

0: Even frame

1: Odd frame

**DPID:** Endpoint data PID

Applies to interrupt/bulk IN endpoints only.

Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The application uses the SD0PID register field to program either DATA0 or DATA1 PID.

0: DATA0

1: DATA1

**Bit 15 USBAEP:** USB active endpoint

Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit.

Bits 14:11 Reserved, must be kept at reset value.

**Bits 10:0 MPSIZ[10:0]:** Maximum packet size

The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.

#### 47.15.47 OTG device IN endpoint x interrupt register (OTG\_DIEPINTx)

Address offset:  $0x908 + 0x20 * x$ , ( $x = 0$  to  $5$ )

Reset value: 0x0000 0080

This register indicates the status of an endpoint with respect to USB- and AHB-related events. It is shown in [Figure 540](#). The application must read this register when the IN endpoints interrupt bit of the core interrupt register (IEPINT in OTG\_GINTSTS) is set. Before the application can read this register, it must first read the device all endpoints interrupt (OTG\_DAINTE) register to get the exact endpoint number for the device endpoint-x interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the OTG\_DAINTE and OTG\_GINTSTS registers.

| Res. | Res. | NAK   | Res. | PKTD<br>RPSTS | Res. | Res. | Res. | TXFE | IN<br>EPNE | IN<br>EPNM | ITTXFE | TOC   | Res. | EP<br>DISD | XFRC  |
|      |      | rc_w1 |      | rc_w1         |      |      |      | r    | rc_w1      | rc_w1      | rc_w1  | rc_w1 |      | rc_w1      | rc_w1 |

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **NAK**: NAK input

The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to unavailability of data in the Tx FIFO.

Bit 12 Reserved, must be kept at reset value.

Bit 11 **PKTDRPSTS**: Packet dropped status

This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt.

Bit 10 Reserved, must be kept at reset value.

Bit 9 Reserved, must be kept at reset value.

Bit 8 Reserved, must be kept at reset value.

Bit 7 **TXFE**: Transmit FIFO empty

This interrupt is asserted when the Tx FIFO for this endpoint is either half or completely empty. The half or completely empty status is determined by the Tx FIFO Empty Level bit in the OTG\_GAHBCFG register (TXFELVL bit in OTG\_GAHBCFG).

Bit 6 **INEPNE**: IN endpoint NAK effective

This bit can be cleared when the application clears the IN endpoint NAK by writing to the CNAK bit in OTG\_DIEPCTLx.

This interrupt indicates that the core has sampled the NAK bit set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit set by the application has taken effect in the core.

This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit.

Bit 5 **INEPNM**: IN token received with EP mismatch

Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one for which the IN token was received. This interrupt is asserted on the endpoint for which the IN token was received.

Bit 4 **ITTXFE**: IN token received when Tx FIFO is empty

Indicates that an IN token was received when the associated Tx FIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint for which the IN token was received.

Bit 3 **TOC**: Timeout condition

Indicates that the core has detected a timeout condition on the USB for the last IN token on this endpoint.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **EPDISD**: Endpoint disabled interrupt

This bit indicates that the endpoint is disabled per the application's request.

Bit 0 **XFRC**: Transfer completed interrupt

This field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint.

#### 47.15.48 OTG device IN endpoint 0 transfer size register (OTG\_DIEPTSIZ0)

Address offset: 0x910

Reset value: 0x0000 0000

The application must modify this register before enabling endpoint 0. Once endpoint 0 is enabled using the endpoint enable bit in the device control endpoint 0 control registers (EPENA in OTG\_DIEPCTL0), the core modifies this register. The application can only read this register once the core has cleared the endpoint enable bit.

Nonzero endpoints use the registers for endpoints 1–3.

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:19 **PKTCNT[1:0]**: Packet count

Indicates the total number of USB packets that constitute the transfer size amount of data for endpoint 0.

This field is decremented every time a packet (maximum size or short packet) is read from the Tx FIFO.

Bits 18:7 Reserved, must be kept at reset value.

Bits 6:0 **XFRSIZ[6:0]**: Transfer size

Indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be set to the maximum packet size of the endpoint, to be interrupted at the end of each packet.

The core decrements this field every time a packet from the external memory is written to the Tx FIFO.

#### 47.15.49 OTG device IN endpoint transmit FIFO status register (OTG\_DTXFSTSx)

Address offset:  $0x918 + 0x20 * x$ , ( $x = 0$  to  $5$ )

Reset value:  $0x0000\ 0200$

This read-only register contains the free space information for the device IN endpoint Tx FIFO.

|                 |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |

| INEPTFSAV[15:0] |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| r               | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **INEPTFSAV[15:0]**: IN endpoint Tx FIFO space available

Indicates the amount of free space available in the endpoint Tx FIFO.

Values are in terms of 32-bit words:

0x0: Endpoint Tx FIFO is full

0x1: 1 word available

0x2: 2 words available

0xn: n words available

Others: Reserved

### 47.15.50 OTG device IN endpoint x transfer size register (OTG\_DIEPTSIZx)

Address offset:  $0x910 + 0x20 * x$ , ( $x = 1$  to  $5$ )

Reset value: 0x0000 0000

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using the endpoint enable bit in the OTG\_DIEPCTLx registers (EPENA bit in OTG\_DIEPCTLx), the core modifies this register. The application can only read this register once the core has cleared the endpoint enable bit.

Bit 31 Reserved, must be kept at reset value.

Bits 30:29 **MCNT[1:0]**: Multi count

For periodic IN endpoints, this field indicates the number of packets that must be transmitted per frame on the USB. The core uses this field to calculate the data PID for isochronous IN endpoints.

01: 1 packet

10: 2 packets

11: 3 packets

Bits 28:19 **PKTCNT[9:0]**: Packet count

Indicates the total number of USB packets that constitute the transfer size amount of data for this endpoint.

This field is decremented every time a packet (maximum size or short packet) is read from the Tx FIFO.

Bits 18:0 **XFRSIZ[18:0]**: Transfer size

This field contains the transfer size in bytes for the current endpoint. The core only interrupts the application after it has exhausted the transfer size amount of data. The transfer size can be set to the maximum packet size of the endpoint, to be interrupted at the end of each packet.

The core decrements this field every time a packet from the external memory is written to the Tx FIFO.

### 47.15.51 OTG device control OUT endpoint 0 control register (OTG\_DOEPCTL0)

Address offset: 0xB00

Reset value: 0x0000 8000

This section describes the OTG\_DOEPCTL0 register. Nonzero control endpoints use registers for endpoints 1–3.

| 31      | 30    | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21    | 20   | 19         | 18   | 17         | 16   |

| USBA EP | Res.  | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.  | Res. | Res.       | Res. | MPSIZ[1:0] |      |
| r       |       |      |      |      |      |      |      |      |      |       |      |            |      | r          | r    |

Bit 31 **EPENA**: Endpoint enable

The application sets this bit to start transmitting data on endpoint 0.

The core clears this bit before setting any of the following interrupts on this endpoint:

- SETUP phase done
- Endpoint disabled
- Transfer completed

Bit 30 **EPDIS**: Endpoint disable

The application cannot disable control OUT endpoint 0.

Bits 29:28 Reserved, must be kept at reset value.

Bit 27 **SNAK**: Set NAK

A write to this bit sets the NAK bit for the endpoint.

Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also set this bit on a transfer completed interrupt, or after a SETUP is received on the endpoint.

Bit 26 **CNAK**: Clear NAK

A write to this bit clears the NAK bit for the endpoint.

Bits 25:22 Reserved, must be kept at reset value.

Bit 21 **STALL**: STALL handshake

The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake.

Bit 20 **SNPM**: Snoop mode

This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory.

Bits 19:18 **EPTYP[1:0]**: Endpoint type

Hardcoded to 2'b00 for control.

Bit 17 **NAKSTS**: NAK status

Indicates the following:

0: The core is transmitting non-NAK handshakes based on the FIFO status.

1: The core is transmitting NAK handshakes on this endpoint.

When either the application or the core sets this bit, the core stops receiving data, even if there is space in the Rx FIFO to accommodate the incoming packet. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake.

Bit 16 Reserved, must be kept at reset value.

Bit 15 **USBAEP**: USB active endpoint

This bit is always set to 1, indicating that a control endpoint 0 is always active in all configurations and interfaces.

Bits 14:2 Reserved, must be kept at reset value.

Bits 1:0 **MPSIZ[1:0]**: Maximum packet size

The maximum packet size for control OUT endpoint 0 is the same as what is programmed in control IN endpoint 0.

00: 64 bytes

01: 32 bytes

10: 16 bytes

11: 8 bytes

#### 47.15.52 OTG device OUT endpoint x interrupt register (OTG\_DOEPINTx)

Address offset:  $0xB08 + 0x20 * x$ , ( $x = 0$  to 5)

Reset value: 0x0000 0080

This register indicates the status of an endpoint with respect to USB- and AHB-related events. It is shown in [Figure 540](#). The application must read this register when the OUT endpoints interrupt bit of the OTG\_GINTSTS register (OEPINT bit in OTG\_GINTSTS) is set. Before the application can read this register, it must first read the OTG\_DAIN register to get the exact endpoint number for the OTG\_DOEPINTx register. The application must clear the appropriate bit in this register to clear the corresponding bits in the OTG\_DAIN and OTG\_GINTSTS registers.

|      |      |       |       |      |      |      |      |      |      |              |             |       |      |            |       |

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **NAK**: NAK input

The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to unavailability of data in the Tx FIFO.

Bit 12 **BERR**: Babble error interrupt

The core generates this interrupt when babble is received for the endpoint.

Bits 11:10 Reserved, must be kept at reset value.

Bit 9 Reserved, must be kept at reset value.

Bit 8 Reserved, must be kept at reset value.

Bit 7 Reserved, must be kept at reset value.

Bit 6 Reserved, must be kept at reset value.

Bit 5 **STSPHSRX**: Status phase received for control write

This interrupt is valid only for control OUT endpoints. This interrupt is generated only after OTG\_FS has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a control write transfer. The application can use this interrupt to ACK or STALL the status phase, after it has decoded the data phase.

Bit 4 **OTEPDIS**: OUT token received when endpoint disabled

Applies only to control OUT endpoints.

Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint for which the OUT token was received.

Bit 3 **STUP**: SETUP phase done

Applies to control OUT endpoint only. Indicates that the SETUP phase for the control endpoint is complete and no more back-to-back SETUP packets were received for the current control transfer. On this interrupt, the application can decode the received SETUP data packet.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **EPDISD**: Endpoint disabled interrupt

This bit indicates that the endpoint is disabled per the application's request.

Bit 0 **XFRC**: Transfer completed interrupt

This field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint.

### 47.15.53 OTG device OUT endpoint 0 transfer size register (OTG\_DOEPTSIZE0)

Address offset: 0xB10

Reset value: 0x0000 0000

The application must modify this register before enabling endpoint 0. Once endpoint 0 is enabled using the endpoint enable bit in the OTG\_DOEPCTL0 registers (EPENA bit in OTG\_DOEPCTL0), the core modifies this register. The application can only read this register once the core has cleared the endpoint enable bit.

Nonzero endpoints use the registers for endpoints 1–5.

Bit 31 Reserved, must be kept at reset value.

Bits 30:29 **STUPCNT[1:0]**: SETUP packet count

This field specifies the number of back-to-back SETUP data packets the endpoint can receive.

01: 1 packet

10: 2 packets

11: 3 packets

Bits 28:20 Reserved, must be kept at reset value.

Bit 19 **PKTCNT**: Packet count

This field is decremented to zero after a packet is written into the Rx FIFO.

Bits 18:7 Reserved, must be kept at reset value.

Bits 6:0 **XFRSIZ[6:0]**: Transfer size

Indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be set to the maximum packet size of the endpoint, to be interrupted at the end of each packet.

The core decrements this field every time a packet is read from the Rx FIFO and written to the external memory.

### 47.15.54 OTG device OUT endpoint x control register (OTG\_DOEPCTLx)

Address offset:  $0xB00 + 0x20 * x$ , ( $x = 1$  to  $5$ )

Reset value: 0x0000 0000

The application uses this register to control the behavior of each logical endpoint other than endpoint 0.

**Bit 31 EPENA:** Endpoint enable

Applies to IN and OUT endpoints.

The application sets this bit to start transmitting data on an endpoint.

The core clears this bit before setting any of the following interrupts on this endpoint:

- SETUP phase done
- Endpoint disabled
- Transfer completed

**Bit 30 EPDIS:** Endpoint disable

The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the endpoint disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the endpoint disabled interrupt. The application must set this bit only if endpoint enable is already set for this endpoint.

**Bit 29 SD1PID:** Set DATA1 PID

Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the endpoint data PID (DPID) field in this register to DATA1.

**SODDFRM:** Set odd frame

Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd frame (EONUM) field to odd frame.

**Bit 28 SD0PID:** Set DATA0 PID

Applies to interrupt/bulk OUT endpoints only.

Writing to this field sets the endpoint data PID (DPID) field in this register to DATA0.

**SEVNFRM:** Set even frame

Applies to isochronous OUT endpoints only.

Writing to this field sets the Even/Odd frame (EONUM) field to even frame.

**Bit 27 SNAK:** Set NAK

A write to this bit sets the NAK bit for the endpoint.

Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also set this bit for OUT endpoints on a transfer completed interrupt, or after a SETUP is received on the endpoint.

**Bit 26 CNAK:** Clear NAK

A write to this bit clears the NAK bit for the endpoint.

Bits 25:22 Reserved, must be kept at reset value.

**Bit 21 STALL:** STALL handshake

Applies to non-control, non-isochronous OUT endpoints only (access type is rw).

The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core.

Applies to control endpoints only (access type is rs).

The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake.

**Bit 20 SNPM:** Snoop mode

This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory.

**Bits 19:18 EPTYP[1:0]:** Endpoint type

This is the transfer type supported by this logical endpoint.

00: Control

01: Isochronous

10: Bulk

11: Interrupt

**Bit 17 NAKSTS:** NAK status

Indicates the following:

0: The core is transmitting non-NAK handshakes based on the FIFO status.

1: The core is transmitting NAK handshakes on this endpoint.

When either the application or the core sets this bit:

The core stops receiving any data on an OUT endpoint, even if there is space in the Rx FIFO to accommodate the incoming packet.

Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake.

**Bit 16 EONUM:** Even/odd frame

Applies to isochronous IN and OUT endpoints only.

Indicates the frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd frame number in which it intends to transmit/receive isochronous data for this endpoint using the SEVNFRM and SODDFRM fields in this register.

0: Even frame

1: Odd frame

**DPID:** Endpoint data PID

Applies to interrupt/bulk OUT endpoints only.

Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The application uses the SD0PID register field to program either DATA0 or DATA1 PID.

0: DATA0

1: DATA1

Bit 15 **USBAEP**: USB active endpoint

Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit.

Bits 14:11 Reserved, must be kept at reset value.

Bits 10:0 **MPSIZ[10:0]**: Maximum packet size

The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.

#### 47.15.55 OTG device OUT endpoint x transfer size register (OTG\_DOEPTSIZE<sub>x</sub>)

Address offset: 0xB10 + 0x20 \* x, (x = 1 to 5)

Reset value: 0x0000 0000

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using endpoint enable bit of the OTG\_DOEPCTL<sub>x</sub> registers (EPENA bit in OTG\_DOEPCTL<sub>x</sub>), the core modifies this register. The application can only read this register once the core has cleared the endpoint enable bit.

Bit 31 Reserved, must be kept at reset value.

Bits 30:29 **RXDPID[1:0]**: Received data PID

Applies to isochronous OUT endpoints only.

This is the data PID received in the last packet for this endpoint.

00: DATA0

10: DATA1

**STUPCNT[1:0]**: SETUP packet count

Applies to control OUT endpoints only.

This field specifies the number of back-to-back SETUP data packets the endpoint can receive.

01: 1 packet

10: 2 packets

11: 3 packets

Bits 28:19 **PKTCNT[9:0]**: Packet count

Indicates the total number of USB packets that constitute the transfer size amount of data for this endpoint.

This field is decremented every time a packet (maximum size or short packet) is written to the Rx FIFO.

Bits 18:0 **XFRSIZ[18:0]**: Transfer size

This field contains the transfer size in bytes for the current endpoint. The core only interrupts the application after it has exhausted the transfer size amount of data. The transfer size can be set to the maximum packet size of the endpoint, to be interrupted at the end of each packet.

The core decrements this field every time a packet is read from the Rx FIFO and written to the external memory.

#### 47.15.56 OTG power and clock gating control register (OTG\_PCGCCTL)

Address offset: 0xE00

Reset value: 0x200B 8000

This register is available in host and device modes.

|      |      |      |      |      |      |      |      |      |           |          |          |      |      |           |          |

| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | SUSP | PHY SLEEP | ENL1 GTG | PHY SUSP | Res. | Res. | GATE HCLK | STPP CLK |
|      |      |      |      |      |      |      |      | r    | r         | rw       | r        |      |      | rw        | rw       |

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **SUSP**: Deep Sleep

This bit indicates that the PHY is in Deep Sleep when in L1 state.

Bit 6 **PHYSLEEP**: PHY in Sleep

This bit indicates that the PHY is in the Sleep state.

Bit 5 **ENL1GTG**: Enable sleep clock gating

When this bit is set, core internal clock gating is enabled in Sleep state if the core cannot assert utmi\_l1\_suspend\_n. When this bit is not set, the PHY clock is not gated in Sleep state.

Bit 4 **PHYSUSP**: PHY suspended

Indicates that the PHY has been suspended. This bit is updated once the PHY is suspended after the application has set the STPPCLK bit.

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **GATEHCLK**: Gate HCLK

The application sets this bit to gate HCLK to modules other than the AHB Slave and Master and wake-up logic when the USB is suspended or the session is not valid. The application clears this bit when the USB is resumed or a new session starts.

Bit 0 **STPPCLK**: Stop PHY clock

The application sets this bit to stop the PHY clock when the USB is suspended, the session is not valid, or the device is disconnected. The application clears this bit when the USB is resumed or a new session starts.

### 47.15.57 OTG\_FS register map

The table below gives the USB OTG register map and reset values.

**Table 329. OTG\_FS register map and reset values**

| Offset | Register name | 31     | 30    | 29    | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21     | 20     | 19    | 18      | 17     | 16     | 15   | 14   | 13   | 12   | 11     | 10     | 9        | 8       | 7        | 6       | 5        | 4       | 3       | 2       | 1     | 0       |   |

1. This bit is reserved for STM32L47x/L48x devices.

Refer to [Section 2.2 on page 75](#) for the register boundary addresses.

## 47.16 OTG\_FS programming model

### 47.16.1 Core initialization

The application must perform the core initialization sequence. If the cable is connected during power-up, the current mode of operation bit in the OTG\_GINTSTS (CMOD bit in OTG\_GINTSTS) reflects the mode. The OTG\_FS controller enters host mode when an “A” plug is connected or device mode when a “B” plug is connected.

This section explains the initialization of the OTG\_FS controller after power-on. The application must follow the initialization sequence irrespective of host or device mode operation. All core global registers are initialized according to the core’s configuration:

1. Program the following fields in the OTG\_GAHBCFG register:
  - Global interrupt mask bit GINTMSK = 1
  - Rx FIFO non-empty (RXFLVL bit in OTG\_GINTSTS)
  - Periodic Tx FIFO empty level
2. Program the following fields in the OTG\_GUSBCFG register:
  - HNP capable bit
  - SRP capable bit
  - OTG\_FS timeout calibration field
  - USB turnaround time field
3. The software must unmask the following bits in the OTG\_GINTMSK register:
  - OTG interrupt mask
  - Mode mismatch interrupt mask
4. The software can read the CMOD bit in OTG\_GINTSTS to determine whether the OTG\_FS controller is operating in host or device mode.

### 47.16.2 Host initialization

To initialize the core as host, the application must perform the following steps:

1. Program the HPRTINT in the OTG\_GINTMSK register to unmask
2. Program the OTG\_HCFG register to select full-speed host
3. Program the PPWR bit in OTG\_HPRT to 1. This drives  $V_{BUS}$  on the USB.
4. Wait for the PCDET interrupt in OTG\_HPRT0. This indicates that a device is connecting to the port.
5. Program the PRST bit in OTG\_HPRT to 1. This starts the reset process.
6. Wait at least 10 ms for the reset process to complete.
7. Program the PRST bit in OTG\_HPRT to 0.
8. Wait for the PENCHNG interrupt in OTG\_HPRT.
9. Read the PSPD bit in OTG\_HPRT to get the enumerated speed.
10. Program the HFIR register with a value corresponding to the selected PHY clock 1
11. Program the FSLSPCS field in the OTG\_HCFG register following the speed of the device detected in step 9. If FSLSPCS has been changed a port reset must be performed.
12. Program the OTG\_GRXFSIZ register to select the size of the receive FIFO.
13. Program the OTG\_HNPTXFSIZ register to select the size and the start address of the Non-periodic transmit FIFO for non-periodic transactions.
14. Program the OTG\_HPTXFSIZ register to select the size and start address of the periodic transmit FIFO for periodic transactions.

To communicate with devices, the system software must initialize and enable at least one channel.

### 47.16.3 Device initialization

The application must perform the following steps to initialize the core as a device on power-up or after a mode change from host to device.

1. Program the following fields in the OTG\_DCFG register:
  - Device speed
  - Non-zero-length status OUT handshake
  - Periodic Frame Interval
2. Clear the DCTL.SDIS bit. The core issues a connect after this bit is cleared.
3. Program the OTG\_GINTMSK register to unmask the following interrupts:
  - USB reset
  - Enumeration done
  - Early suspend
  - USB suspend
  - SOF
4. Wait for the USBRST interrupt in OTG\_GINTSTS. It indicates that a reset has been detected on the USB that lasts for about 10 ms on receiving this interrupt.
5. Wait for the ENUMDNE interrupt in OTG\_GINTSTS. This interrupt indicates the end of reset on the USB. On receiving this interrupt, the application must read the OTG\_DSTS

register to determine the enumeration speed and perform the steps listed in [Endpoint initialization on enumeration completion on page 1785](#).

At this point, the device is ready to accept SOF packets and perform control transfers on control endpoint 0.

## 47.16.4 Host programming model

### Channel initialization

The application must initialize one or more channels before it can communicate with connected devices. To initialize and enable a channel, the application must perform the following steps:

1. Program the OTG\_GINTMSK register to unmask the following:
2. Channel interrupt
  - Non-periodic transmit FIFO empty for OUT transactions (applicable when operating in pipelined transaction-level with the packet count field programmed with more than one).
  - Non-periodic transmit FIFO half-empty for OUT transactions (applicable when operating in pipelined transaction-level with the packet count field programmed with more than one).
3. Program the OTG\_HAINTMSK register to unmask the selected channels' interrupts.
4. Program the OTG\_HCINTMSK register to unmask the transaction-related interrupts of interest given in the host channel interrupt register.
5. Program the selected channel's OTG\_HCTSIZx register with the total transfer size, in bytes, and the expected number of packets, including short packets. The application must program the PID field with the initial data PID (to be used on the first OUT transaction or to be expected from the first IN transaction).
6. Program the OTG\_HCCHARx register of the selected channel with the device's endpoint characteristics, such as type, speed, direction, and so forth. (The channel can be enabled by setting the channel enable bit to 1 only when the application is ready to transmit or receive any packet).

### Halting a channel

The application can disable any channel by programming the OTG\_HCCHARx register with the CHDIS and CHENA bits set to 1. This enables the OTG\_FS host to flush the posted requests (if any) and generates a channel halted interrupt. The application must wait for the CHH interrupt in OTG\_HCINTx before reallocating the channel for other transactions. The OTG\_FS host does not interrupt the transaction that has already been started on the USB.

Before disabling a channel, the application must ensure that there is at least one free space available in the non-periodic request queue (when disabling a non-periodic channel) or the periodic request queue (when disabling a periodic channel). The application can simply flush the posted requests when the request queue is full (before disabling the channel), by programming the OTG\_HCCHARx register with the CHDIS bit set to 1 which automatically clears the CHENA bit to 0.

The application is expected to disable a channel on any of the following conditions:

1. When an STALL, TXERR, BBERR or DTERR interrupt in OTG\_HCINTx is received for an IN or OUT channel. The application must be able to receive other interrupts (DTERR, Nak, data, TXERR) for the same channel before receiving the halt.
2. When a DISCINT (disconnect device) interrupt in OTG\_GINTSTS is received. (The application is expected to disable all enabled channels).
3. When the application aborts a transfer before normal completion.

### Operational model

The application must initialize a channel before communicating to the connected device. This section explains the sequence of operation to be performed for different types of USB transactions.

- **Writing the transmit FIFO**

The OTG\_FS host automatically writes an entry (OUT request) to the periodic/non-periodic request queue, along with the last 32-bit word write of a packet. The application must ensure that at least one free space is available in the periodic/non-periodic request queue before starting to write to the transmit FIFO. The application must always write to the transmit FIFO in 32-bit words. If the packet size is non-32-bit word aligned, the application must use padding. The OTG\_FS host determines the actual packet size based on the programmed maximum packet size and transfer size.

**Figure 541. Transmit FIFO write task**

- **Reading the receive FIFO**

The application must ignore all packet statuses other than IN data packet (bx0010).

Figure 542. Receive FIFO read task

- **Bulk and control OUT/SETUP transactions**

A typical bulk or control OUT/SETUP pipelined transaction-level operation is shown in [Figure 543](#). See channel 1 (ch\_1). Two bulk OUT packets are transmitted. A control SETUP transaction operates in the same way but has only one packet. The assumptions are:

- The application is attempting to send two maximum-packet-size packets (transfer size = 1,024 bytes).
- The non-periodic transmit FIFO can hold two packets (128 bytes for FS).
- The non-periodic request queue depth = 4.

- **Normal bulk and control OUT/SETUP operations**

The sequence of operations in (channel 1) is as follows:

1. Initialize channel 1
2. Write the first packet for channel 1
3. Along with the last word write, the core writes an entry to the non-periodic request queue
4. As soon as the non-periodic queue becomes non-empty, the core attempts to send an OUT token in the current frame
5. Write the second (last) packet for channel 1
6. The core generates the XFRC interrupt as soon as the last transaction is completed successfully
7. In response to the XFRC interrupt, de-allocate the channel for other transfers
8. Handling non-ACK responses

Figure 543. Normal bulk/control OUT/SETUP

1. The grayed elements are not relevant in the context of this figure.

The channel-specific interrupt service routine for bulk and control OUT/SETUP transactions is shown in the following code samples.

- **Interrupt service routine for bulk/control OUT/SETUP and bulk/control IN transactions**

- a) Bulk/control OUT/SETUP

```

Unmask (NAK/TXERR/STALL/XFRC)
if (XFRC)
{
    Reset Error Count
    Mask ACK
    De-allocate Channel
}
else if (STALL)
{
    Transfer Done = 1
    Unmask CHH
    Disable Channel
}
else if (NAK or TXERR )
{
    Rewind Buffer Pointers
    Unmask CHH
    Disable Channel
    if (TXERR)
    {
        Increment Error Count
        Unmask ACK
    }
    else
    {
        Reset Error Count
    }
}
else if (CHH)
{
    Mask CHH
    if (Transfer Done or (Error_count == 3))
    {
        De-allocate Channel
    }
    else
    {
        Re-initialize Channel
    }
}

```

```
else if (ACK)
{
    Reset Error Count
    Mask ACK
}
```

The application is expected to write the data packets into the transmit FIFO when the space is available in the transmit FIFO and the request queue. The application can make use of the NPTXFE interrupt in OTG\_GINTSTS to find the transmit FIFO space.

b) Bulk/control IN

```
Unmask (TXERR/XFRC/BBERR/STALL/DTERR)
if (XFRC)
{
    Reset Error Count
    Unmask CHH
    Disable Channel
    Reset Error Count
    Mask ACK
}
else if (TXERR or BBERR or STALL)
{
    Unmask CHH
    Disable Channel
    if (TXERR)
    {
        Increment Error Count
        Unmask ACK
    }
}
else if (CHH)
{
    Mask CHH
    if (Transfer Done or (Error_count == 3))
    {
        De-allocate Channel
    }
    else
    {
        Re-initialize Channel
    }
}
else if (ACK)
{
    Reset Error Count
    Mask ACK
}
```

```
else if (DTERR)
{
    Reset Error Count
}
```

The application is expected to write the requests as and when the request queue space is available and until the XFRC interrupt is received.

- **Bulk and control IN transactions**

A typical bulk or control IN pipelined transaction-level operation is shown in [Figure 544](#). See channel 2 (ch\_2). The assumptions are:

- The application is attempting to receive two maximum-packet-size packets (transfer size = 1 024 bytes).
- The receive FIFO can contain at least one maximum-packet-size packet and two status words per packet (72 bytes for FS).
- The non-periodic request queue depth = 4.

Figure 544. Bulk/control IN transactions

ai15675b

The sequence of operations is as follows:

1. Initialize channel 2.
  2. Set the CHENA bit in OTG\_HCCHAR2 to write an IN request to the non-periodic request queue.
  3. The core attempts to send an IN token after completing the current OUT transaction.
  4. The core generates an RXFLVL interrupt as soon as the received packet is written to the receive FIFO.
  5. In response to the RXFLVL interrupt, mask the RXFLVL interrupt and read the received packet status to determine the number of bytes received, then read the receive FIFO accordingly. Following this, unmask the RXFLVL interrupt.
  6. The core generates the RXFLVL interrupt for the transfer completion status entry in the receive FIFO.
  7. The application must read and ignore the receive packet status when the receive packet status is not an IN data packet (PKTSTS in OTG\_GRXSTSR  $\neq$  0b0010).
  8. The core generates the XFRC interrupt as soon as the receive packet status is read.
  9. In response to the XFRC interrupt, disable the channel and stop writing the OTG\_HCCHAR2 register for further requests. The core writes a channel disable request to the non-periodic request queue as soon as the OTG\_HCCHAR2 register is written.
  10. The core generates the RXFLVL interrupt as soon as the halt status is written to the receive FIFO.
  11. Read and ignore the receive packet status.
  12. The core generates a CHH interrupt as soon as the halt status is popped from the receive FIFO.
  13. In response to the CHH interrupt, de-allocate the channel for other transfers.
  14. Handling non-ACK responses
- **Control transactions**

Setup, data, and status stages of a control transfer must be performed as three separate transfers. setup-, data- or status-stage OUT transactions are performed similarly to the bulk OUT transactions explained previously. Data- or status-stage IN transactions are performed similarly to the bulk IN transactions explained previously. For all three stages, the application is expected to set the EPTYP field in

OTG\_HCCHAR1 to control. During the setup stage, the application is expected to set the PID field in OTG\_HCTSIZ1 to SETUP.

- **Interrupt OUT transactions**

A typical interrupt OUT operation is shown in [Figure 545](#). The assumptions are:

- The application is attempting to send one packet in every frame (up to 1 maximum packet size), starting with the odd frame (transfer size = 1 024 bytes)
- The periodic transmit FIFO can hold one packet (1 Kbyte)
- Periodic request queue depth = 4

The sequence of operations is as follows:

1. Initialize and enable channel 1. The application must set the ODDFRM bit in OTG\_HCCHAR1.
2. Write the first packet for channel 1.
3. Along with the last word write of each packet, the OTG\_FS host writes an entry to the periodic request queue.
4. The OTG\_FS host attempts to send an OUT token in the next (odd) frame.
5. The OTG\_FS host generates an XFRC interrupt as soon as the last packet is transmitted successfully.
6. In response to the XFRC interrupt, reinitialize the channel for the next transfer.

Figure 545. Normal interrupt OUT

1. The grayed elements are not relevant in the context of this figure.

- **Interrupt service routine for interrupt OUT/IN transactions**

- a) Interrupt OUT

**Unmask (NAK/TXERR/STALL/XFRC/FRMOR)**

```
if (XFRC)
{
    Reset Error Count
    Mask ACK
    De-allocate Channel
}
else
    if (STALL or FRMOR)
    {
        Mask ACK
        Unmask CHH
        Disable Channel
        if (STALL)
        {
            Transfer Done = 1
        }
    }
else
    if (NAK or TXERR)
    {
        Rewind Buffer Pointers
        Reset Error Count
        Mask ACK
        Unmask CHH
        Disable Channel
    }
else
    if (CHH)
    {
        Mask CHH
        if (Transfer Done or (Error_count == 3))
        {
            De-allocate Channel
        }
        else
        {
            Re-initialize Channel (in next b_interval - 1 Frame)
        }
    }
else
    if (ACK)
    {
        Reset Error Count
        Mask ACK
    }
```

The application uses the NPTXFE interrupt in OTG\_GINTSTS to find the transmit FIFO space.

Interrupt IN

Unmask (NAK/TXERR/XFRC/BBERR/STALL/FRMOR/DTERR)

```
if (XFRC)
{
    Reset Error Count
    Mask ACK
    if (OTG_HCTSIZx.PKTCNT == 0)
    {
        De-allocate Channel
    }
    else
    {
        Transfer Done = 1
        Unmask CHH
        Disable Channel
    }
}
else
    if (STALL or FRMOR or NAK or DTERR or BBERR)
    {
        Mask ACK
        Unmask CHH
        Disable Channel
        if (STALL or BBERR)
        {
            Reset Error Count
            Transfer Done = 1
        }
        else
            if (!FRMOR)
            {
                Reset Error Count
            }
    }
else
    if (TXERR)
    {
        Increment Error Count
        Unmask ACK
        Unmask CHH
        Disable Channel
    }
else
```

```

if (CHH)
{
    Mask CHH
    if (Transfer Done or (Error_count == 3))
    {
        De-allocate Channel
    }
    else
        Re-initialize Channel (in next b_interval - 1 /Frame)
}
}
else
    if (ACK)
    {
        Reset Error Count
        Mask ACK
    }
}

```

- **Interrupt IN transactions**

The assumptions are:

- The application is attempting to receive one packet (up to 1 maximum packet size) in every frame, starting with odd (transfer size = 1 024 bytes).
- The receive FIFO can hold at least one maximum-packet-size packet and two status words per packet (1 031 bytes).
- Periodic request queue depth = 4.

- **Normal interrupt IN operation**

The sequence of operations is as follows:

1. Initialize channel 2. The application must set the ODDFRM bit in OTG\_HCCHAR2.
2. Set the CHENA bit in OTG\_HCCHAR2 to write an IN request to the periodic request queue.
3. The OTG\_FS host writes an IN request to the periodic request queue for each OTG\_HCCHAR2 register write with the CHENA bit set.
4. The OTG\_FS host attempts to send an IN token in the next (odd) frame.
5. As soon as the IN packet is received and written to the receive FIFO, the OTG\_FS host generates an RXFLVL interrupt.
6. In response to the RXFLVL interrupt, read the received packet status to determine the number of bytes received, then read the receive FIFO accordingly. The application must mask the RXFLVL interrupt before reading the receive FIFO, and unmask after reading the entire packet.
7. The core generates the RXFLVL interrupt for the transfer completion status entry in the receive FIFO. The application must read and ignore the receive packet status when the receive packet status is not an IN data packet (PKTSTS in GRXSTSR ≠ 0b0010).
8. The core generates an XFRC interrupt as soon as the receive packet status is read.
9. In response to the XFRC interrupt, read the PKTCNT field in OTG\_HCTSIZ2. If the PKTCNT bit in OTG\_HCTSIZ2 is not equal to 0, disable the channel before re-

initializing the channel for the next transfer, if any). If PKTCNT bit in OTG\_HCTSIZ2 = 0, reinitialize the channel for the next transfer. This time, the application must reset the ODDFRM bit in OTG\_HCCHAR2.

### Figure 546. Normal interrupt IN

1. The grayed elements are not relevant in the context of this figure.

- **Isochronous OUT transactions**

A typical isochronous OUT operation is shown in [Figure 547](#). The assumptions are:

- The application is attempting to send one packet every frame (up to 1 maximum)

packet size), starting with an odd frame. (transfer size = 1 024 bytes).

- The periodic transmit FIFO can hold one packet (1 Kbyte).
- Periodic request queue depth = 4.

The sequence of operations is as follows:

1. Initialize and enable channel 1. The application must set the ODDFRM bit in OTG\_HCCHAR1.
2. Write the first packet for channel 1.
3. Along with the last word write of each packet, the OTG\_FS host writes an entry to the periodic request queue.
4. The OTG\_FS host attempts to send the OUT token in the next frame (odd).
5. The OTG\_FS host generates the XFRC interrupt as soon as the last packet is transmitted successfully.
6. In response to the XFRC interrupt, reinitialize the channel for the next transfer.
7. Handling non-ACK responses

    {
        Mask CHH
        De-allocate Channel
    }
Code sample: Isochronous IN
Unmask (TXERR/XFRC/FRMOR/BBERR)
if (XFRC or FRMOR)
{
    if (XFRC and (OTG_HCTSIZx.PKTCNT == 0))
    {
        Reset Error Count
        De-allocate Channel
    }
    else
    {
        Unmask CHH
        Disable Channel
    }
}
else
    if (TXERR or BBERR)
    {
        Increment Error Count
        Unmask CHH
        Disable Channel
    }
    else
    if (CHH)
    {
        Mask CHH
        if (Transfer Done or (Error_count == 3))
        {
            De-allocate Channel
        }
    }
}
```

```

else
{
    Re-initialize Channel
}
}

```

- **Isochronous IN transactions**

The assumptions are:

- The application is attempting to receive one packet (up to 1 maximum packet size) in every frame starting with the next odd frame (transfer size = 1 024 bytes).
- The receive FIFO can hold at least one maximum-packet-size packet and two status word per packet (1 031 bytes).
- Periodic request queue depth = 4.

The sequence of operations is as follows:

1. Initialize channel 2. The application must set the ODDFRM bit in OTG\_HCCHAR2.
2. Set the CHENA bit in OTG\_HCCHAR2 to write an IN request to the periodic request queue.
3. The OTG\_FS host writes an IN request to the periodic request queue for each OTG\_HCCHAR2 register write with the CHENA bit set.
4. The OTG\_FS host attempts to send an IN token in the next odd frame.
5. As soon as the IN packet is received and written to the receive FIFO, the OTG\_FS host generates an RXFLVL interrupt.
6. In response to the RXFLVL interrupt, read the received packet status to determine the number of bytes received, then read the receive FIFO accordingly. The application must mask the RXFLVL interrupt before reading the receive FIFO, and unmask it after reading the entire packet.
7. The core generates an RXFLVL interrupt for the transfer completion status entry in the receive FIFO. This time, the application must read and ignore the receive packet status when the receive packet status is not an IN data packet (PKTSTS bit in OTG\_GRXSTSR ≠ 0b0010).
8. The core generates an XFRC interrupt as soon as the receive packet status is read.
9. In response to the XFRC interrupt, read the PKTCNT field in OTG\_HCTSIZ2. If PKTCNT ≠ 0 in OTG\_HCTSIZ2, disable the channel before re-initializing the channel for the next transfer, if any. If PKTCNT = 0 in OTG\_HCTSIZ2, reinitialize the channel for the next transfer. This time, the application must reset the ODDFRM bit in OTG\_HCCHAR2.

Figure 548. Isochronous IN transactions

1. The grayed elements are not relevant in the context of this figure.

- Selecting the queue depth**

Choose the periodic and non-periodic request queue depths carefully to match the number of periodic/non-periodic endpoints accessed.

The non-periodic request queue depth affects the performance of non-periodic

transfers. The deeper the queue (along with sufficient FIFO size), the more often the core is able to pipeline non-periodic transfers. If the queue size is small, the core is able to put in new requests only when the queue space is freed up.

The core's periodic request queue depth is critical to perform periodic transfers as scheduled. Select the periodic queue depth, based on the number of periodic transfers scheduled in a microframe. If the periodic request queue depth is smaller than the periodic transfers scheduled in a microframe, a frame overrun condition occurs.

- **Handling babble conditions**

OTG\_FS controller handles two cases of babble: packet babble and port babble.

Packet babble occurs if the device sends more data than the maximum packet size for the channel. Port babble occurs if the core continues to receive data from the device at EOF2 (the end of frame 2, which is very close to SOF).

When OTG\_FS controller detects a packet babble, it stops writing data into the Rx buffer and waits for the end of packet (EOP). When it detects an EOP, it flushes already written data in the Rx buffer and generates a Babble interrupt to the application.

When OTG\_FS controller detects a port babble, it flushes the Rx FIFO and disables the port. The core then generates a port disabled interrupt (HPRTINT in OTG\_GINTSTS, PENCHNG in OTG\_HPRT). On receiving this interrupt, the application must determine that this is not due to an overcurrent condition (another cause of the port disabled interrupt) by checking POCA in OTG\_HPRT, then perform a soft reset. The core does not send any more tokens after it has detected a port babble condition.

## 47.16.5 Device programming model

### Endpoint initialization on USB reset

1. Set the NAK bit for all OUT endpoints
  - SNAK = 1 in OTG\_DOEPCTLx (for all OUT endpoints)
2. Unmask the following interrupt bits
  - INEP0 = 1 in OTG\_DAINMSK (control 0 IN endpoint)
  - OUTEP0 = 1 in OTG\_DAINMSK (control 0 OUT endpoint)
  - STUPM = 1 in OTG\_DOEPMSK
  - XFRCM = 1 in OTG\_DOEPMSK
  - XFRCM = 1 in OTG\_DIEPMSK
  - TOM = 1 in OTG\_DIEPMSK
3. Set up the data FIFO RAM for each of the FIFOs
  - Program the OTG\_GRXFSIZ register, to be able to receive control OUT data and setup data. If thresholding is not enabled, at a minimum, this must be equal to 1 max packet size of control endpoint 0 + 2 words (for the status of the control OUT data packet) + 10 words (for setup packets).
  - Program the OTG\_DIEPTXF0 register (depending on the FIFO number chosen) to be able to transmit control IN data. At a minimum, this must be equal to 1 max packet size of control endpoint 0.
4. Program the following fields in the endpoint-specific registers for control OUT endpoint 0 to receive a SETUP packet
  - STUPCNT = 3 in OTG\_DOEPTSIZ0 (to receive up to 3 back-to-back SETUP packets)

At this point, all initialization required to receive SETUP packets is done.

### Endpoint initialization on enumeration completion

1. On the Enumeration Done interrupt (ENUMDNE in OTG\_GINTSTS), read the OTG\_DSTS register to determine the enumeration speed.
2. Program the MPSIZ field in OTG\_DIEPCTL0 to set the maximum packet size. This step configures control endpoint 0. The maximum packet size for a control endpoint depends on the enumeration speed.

At this point, the device is ready to receive SOF packets and is configured to perform control transfers on control endpoint 0.

### Endpoint initialization on SetAddress command

This section describes what the application must do when it receives a SetAddress command in a SETUP packet.

1. Program the OTG\_DCFG register with the device address received in the SetAddress command
2. Program the core to send out a status IN packet

### Endpoint initialization on SetConfiguration/SetInterface command

This section describes what the application must do when it receives a SetConfiguration or SetInterface command in a SETUP packet.

1. When a SetConfiguration command is received, the application must program the endpoint registers to configure them with the characteristics of the valid endpoints in the new configuration.
2. When a SetInterface command is received, the application must program the endpoint registers of the endpoints affected by this command.
3. Some endpoints that were active in the prior configuration or alternate setting are not valid in the new configuration or alternate setting. These invalid endpoints must be deactivated.
4. Unmask the interrupt for each active endpoint and mask the interrupts for all inactive endpoints in the OTG\_DAINMSK register.
5. Set up the data FIFO RAM for each FIFO.
6. After all required endpoints are configured; the application must program the core to send a status IN packet.

At this point, the device core is configured to receive and transmit any type of data packet.

### Endpoint activation

This section describes the steps required to activate a device endpoint or to configure an existing device endpoint to a new type.

1. Program the characteristics of the required endpoint into the following fields of the OTG\_DIEPCTLx register (for IN or bidirectional endpoints) or the OTG\_DOEPCTLx register (for OUT or bidirectional endpoints).
  - Maximum packet size
  - USB active endpoint = 1
  - Endpoint start data toggle (for interrupt and bulk endpoints)
  - Endpoint type
  - Tx FIFO number
2. Once the endpoint is activated, the core starts decoding the tokens addressed to that endpoint and sends out a valid handshake for each valid token received for the endpoint.

### Endpoint deactivation

This section describes the steps required to deactivate an existing endpoint.

1. In the endpoint to be deactivated, clear the USB active endpoint bit in the OTG\_DIEPCTLx register (for IN or bidirectional endpoints) or the OTG\_DOEPCTLx register (for OUT or bidirectional endpoints).
2. Once the endpoint is deactivated, the core ignores tokens addressed to that endpoint, which results in a timeout on the USB.

*Note:* The application must meet the following conditions to set up the device core to handle traffic:

*NPTXFEM and RXFLVLM in the OTG\_GINTMSK register must be cleared.*

### Operational model

SETUP and OUT data transfers:

This section describes the internal data flow and application-level operations during data OUT transfers and SETUP transactions.

#### • Packet read

This section describes how to read packets (OUT data and SETUP packets) from the receive FIFO.

1. On catching an RXFLVL interrupt (OTG\_GINTSTS register), the application must read the receive status pop register (OTG\_GRXSTSP).
2. The application can mask the RXFLVL interrupt (in OTG\_GINTSTS) by writing to RXFLVLM = 0 (in OTG\_GINTMSK), until it has read the packet from the receive FIFO.
3. If the received packet's byte count is not 0, the byte count amount of data is popped from the receive data FIFO and stored in memory. If the received packet byte count is 0, no data is popped from the receive data FIFO.
4. The receive status readout of the packet of FIFO indicates one of the following:
  - a) Global OUT NAK pattern:  
 PKTSTS = Global OUT NAK, BCNT = 0x000, EPNUM = (0x0),  
 DPID = (0b00).  
 These data indicate that the global OUT NAK bit has taken effect.
  - b) SETUP packet pattern:  
 PKTSTS = SETUP, BCNT = 0x008, EPNUM = Control EP Num,

- DPID = DATA0. These data indicate that a SETUP packet for the specified endpoint is now available for reading from the receive FIFO.
- c) Setup stage done pattern:  
 PKTSTS = Setup Stage Done, BCNT = 0x0, EPNUM = Control EP Num, DPID = (0b00).  
 These data indicate that the setup stage for the specified endpoint has completed and the data stage has started. After this entry is popped from the receive FIFO, the core asserts a setup interrupt on the specified control OUT endpoint.
- d) Data OUT packet pattern:  
 PKTSTS = DataOUT, BCNT = size of the received data OUT packet ( $0 \leq \text{BCNT} \leq 1024$ ), EPNUM = EPNUM on which the packet was received, DPID = Actual Data PID.
- e) Data transfer completed pattern:  
 PKTSTS = Data OUT transfer done, BCNT = 0x0, EPNUM = OUT EP Num on which the data transfer is complete, DPID = (0b00).  
 These data indicate that an OUT data transfer for the specified OUT endpoint has completed. After this entry is popped from the receive FIFO, the core asserts a transfer completed interrupt on the specified OUT endpoint.
5. After the data payload is popped from the receive FIFO, the RXFLVL interrupt (OTG\_GINTSTS) must be unmasked.
6. Steps 1–5 are repeated every time the application detects assertion of the interrupt line due to RXFLVL in OTG\_GINTSTS. Reading an empty receive FIFO can result in undefined core behavior.

Figure 549 provides a flowchart of the above procedure.

**Figure 549. Receive FIFO packet read**

#### SETUP transactions

This section describes how the core handles SETUP packets and the application's sequence for handling SETUP transactions.

- **Application requirements**

1. To receive a SETUP packet, the STUPCNT field (OTG\_DOEPTSIZE<sub>x</sub>) in a control OUT endpoint must be programmed to a non-zero value. When the application programs the STUPCNT field to a non-zero value, the core receives SETUP packets and writes them to the receive FIFO, irrespective of the NAK status and EPENA bit setting in OTG\_DOEPTCTL<sub>x</sub>. The STUPCNT field is decremented every time the control endpoint receives a SETUP packet. If the STUPCNT field is not programmed to a proper value before receiving a SETUP packet, the core still receives the SETUP packet and decrements the STUPCNT field, but the application may not be able to determine the correct number of SETUP packets received in the setup stage of a control transfer.
  - STUPCNT = 3 in OTG\_DOEPTSIZE<sub>x</sub>
2. The application must always allocate some extra space in the receive data FIFO, to be able to receive up to three SETUP packets on a control endpoint.
  - The space to be reserved is 10 words. Three words are required for the first SETUP packet, 1 word is required for the setup stage done word and 6 words are required to store two extra SETUP packets among all control endpoints.
  - 3 words per SETUP packet are required to store 8 bytes of SETUP data and 4 bytes of SETUP status (setup packet pattern). The core reserves this space in the receive data FIFO to write SETUP data only, and never uses this space for data packets.
3. The application must read the 2 words of the SETUP packet from the receive FIFO.
4. The application must read and discard the setup stage done word from the receive FIFO.

- **Internal data flow**

1. When a SETUP packet is received, the core writes the received data to the receive FIFO, without checking for available space in the receive FIFO and irrespective of the endpoint's NAK and STALL bit settings.
  - The core internally sets the IN NAK and OUT NAK bits for the control IN/OUT endpoints on which the SETUP packet was received.
2. For every SETUP packet received on the USB, 3 words of data are written to the receive FIFO, and the STUPCNT field is decremented by 1.
  - The first word contains control information used internally by the core
  - The second word contains the first 4 bytes of the SETUP command
  - The third word contains the last 4 bytes of the SETUP command
3. When the setup stage changes to a data IN/OUT stage, the core writes an entry (setup stage done word) to the receive FIFO, indicating the completion of the setup stage.
4. On the AHB side, SETUP packets are emptied by the application.
5. When the application pops the setup stage done word from the receive FIFO, the core interrupts the application with an STUP interrupt (OTG\_DOEPINT<sub>x</sub>), indicating it can process the received SETUP packet.
6. The core clears the endpoint enable bit for control OUT endpoints.

- **Application programming sequence**

1. Program the OTG\_DOEPTSIZx register.
  - STUPCNT = 3
2. Wait for the RXFLVL interrupt (OTG\_GINTSTS) and empty the data packets from the receive FIFO.
3. Assertion of the STUP interrupt (OTG\_DOEPINTx) marks a successful completion of the SETUP data transfer.
  - On this interrupt, the application must read the OTG\_DOEPTSIZx register to determine the number of SETUP packets received and process the last received SETUP packet.

Figure 550. Processing a SETUP packet

#### • Handling more than three back-to-back SETUP packets

Per the USB 2.0 specification, normally, during a SETUP packet error, a host does not send more than three back-to-back SETUP packets to the same endpoint. However, the USB 2.0 specification does not limit the number of back-to-back SETUP packets a host can send to the same endpoint. When this condition occurs, the OTG\_FS controller generates an interrupt (B2BSTUP in OTG\_DOEPINTx).

#### • Setting the global OUT NAK

Internal data flow:

1. When the application sets the Global OUT NAK (SGONAK bit in OTG\_DCTL), the core stops writing data, except SETUP packets, to the receive FIFO. Irrespective of the

space availability in the receive FIFO, non-isochronous OUT tokens receive a NAK handshake response, and the core ignores isochronous OUT data packets

2. The core writes the Global OUT NAK pattern to the receive FIFO. The application must reserve enough receive FIFO space to write this data pattern.
3. When the application pops the Global OUT NAK pattern word from the receive FIFO, the core sets the GONAKEFF interrupt (OTG\_GINTSTS).
4. Once the application detects this interrupt, it can assume that the core is in Global OUT NAK mode. The application can clear this interrupt by clearing the SGONAK bit in OTG\_DCTL.

Application programming sequence:

1. To stop receiving any kind of data in the receive FIFO, the application must set the Global OUT NAK bit by programming the following field:
  - SGONAK = 1 in OTG\_DCTL
2. Wait for the assertion of the GONAKEFF interrupt in OTG\_GINTSTS. When asserted, this interrupt indicates that the core has stopped receiving any type of data except SETUP packets.
3. The application can receive valid OUT packets after it has set SGONAK in OTG\_DCTL and before the core asserts the GONAKEFF interrupt (OTG\_GINTSTS).
4. The application can temporarily mask this interrupt by writing to the GONAKEFFM bit in the OTG\_GINTMSK register.
  - GONAKEFFM = 0 in the OTG\_GINTMSK register
5. Whenever the application is ready to exit the Global OUT NAK mode, it must clear the SGONAK bit in OTG\_DCTL. This also clears the GONAKEFF interrupt (OTG\_GINTSTS).
  - CGONAK = 1 in OTG\_DCTL
6. If the application has masked this interrupt earlier, it must be unmasked as follows:
  - GONAKEFFM = 1 in OTG\_GINTMSK

- **Disabling an OUT endpoint**

The application must use this sequence to disable an OUT endpoint that it has enabled.

Application programming sequence:

1. Before disabling any OUT endpoint, the application must enable Global OUT NAK mode in the core.
  - SGONAK = 1 in OTG\_DCTL
2. Wait for the GONAKEFF interrupt (OTG\_GINTSTS)
3. Disable the required OUT endpoint by programming the following fields:
  - EPDIS = 1 in OTG\_DOEPCTLx
  - SNAK = 1 in OTG\_DOEPCTLx
4. Wait for the EPDISD interrupt (OTG\_DOEPINTx), which indicates that the OUT endpoint is completely disabled. When the EPDISD interrupt is asserted, the core also clears the following bits:
  - EPDIS = 0 in OTG\_DOEPCTLx
  - EPENA = 0 in OTG\_DOEPCTLx
5. The application must clear the Global OUT NAK bit to start receiving data from other non-disabled OUT endpoints.
  - SGONAK = 0 in OTG\_DCTL

#### • Transfer Stop Programming for OUT endpoints

The application must use the following programming sequence to stop any transfers (because of an interrupt from the host, typically a reset).

##### Sequence of operations:

1. Enable all OUT endpoints by setting
  - EPENA = 1 in all OTG\_DOEPCTLx registers.
2. Flush the RxFIFO as follows
  - Poll OTG\_GRSTCTL.AHBIDL until it is 1. This indicates that AHB master is idle.
  - Perform read modify write operation on OTG\_GRSTCTL.RXFFLSH = 1
  - Poll OTG\_GRSTCTL.RXFFLSH until it is 0, but also using a timeout of less than 10 milli-seconds (corresponds to minimum reset signaling duration). If 0 is seen before the timeout, then the RxFIFO flush is successful. If at the moment the timeout occurs, there is still a 1, (this may be due to a packet on EP0 coming from the host) then go back (once only) to the previous step (“Perform read modify write operation”).
3. Before disabling any OUT endpoint, the application must enable Global OUT NAK mode in the core, according to the instructions in [“Setting the global OUT NAK on page 1789”](#). This ensures that data in the RxFIFO is sent to the application successfully. Set SGONAK = 1 in OTG\_DCTL
4. Wait for the GONAKEFF interrupt (OTG\_GINTSTS)
5. Disable all active OUT endpoints by programming the following register bits:
  - EPDIS = 1 in registers OTG\_DOEPCTLx
  - SNAK = 1 in registers OTG\_DOEPCTLx
6. Wait for the EPDIS interrupt in OTG\_DOEPINTx for each OUT endpoint programmed in the previous step. The EPDIS interrupt in OTG\_DOEPINTx indicates that the

corresponding OUT endpoint is completely disabled. When the EPDIS interrupt is asserted, the following bits are cleared:

- EPENA = 0 in registers OTG\_DOEPCTLx
- EPDIS = 0 in registers OTG\_DOEPCTLx
- SNAK = 0 in registers OTG\_DOEPCTLx

#### • Generic non-isochronous OUT data transfers

This section describes a regular non-isochronous OUT data transfer (control, bulk, or interrupt).

Application requirements:

1. Before setting up an OUT transfer, the application must allocate a buffer in the memory to accommodate all data to be received as part of the OUT transfer.
2. For OUT transfers, the transfer size field in the endpoint's transfer size register must be a multiple of the maximum packet size of the endpoint, adjusted to the word boundary.
  - $\text{transfer size}[\text{EPNUM}] = n \times (\text{MPSIZ}[\text{EPNUM}] + 4 - (\text{MPSIZ}[\text{EPNUM}] \bmod 4))$
  - $\text{packet count}[\text{EPNUM}] = n$
  - $n > 0$
3. On any OUT endpoint interrupt, the application must read the endpoint's transfer size register to calculate the size of the payload in the memory. The received payload size can be less than the programmed transfer size.
  - $\text{Payload size in memory} = \text{application programmed initial transfer size} - \text{core updated final transfer size}$
  - $\text{Number of USB packets in which this payload was received} = \text{application programmed initial packet count} - \text{core updated final packet count}$

Internal data flow:

1. The application must set the transfer size and packet count fields in the endpoint-specific registers, clear the NAK bit, and enable the endpoint to receive the data.
2. Once the NAK bit is cleared, the core starts receiving data and writes it to the receive FIFO, as long as there is space in the receive FIFO. For every data packet received on the USB, the data packet and its status are written to the receive FIFO. Every packet (maximum packet size or short packet) written to the receive FIFO decrements the packet count field for that endpoint by 1.
  - OUT data packets received with bad data CRC are flushed from the receive FIFO automatically.
  - After sending an ACK for the packet on the USB, the core discards non-isochronous OUT data packets that the host, which cannot detect the ACK, re-sends. The application does not detect multiple back-to-back data OUT packets on the same endpoint with the same data PID. In this case the packet count is not decremented.
  - If there is no space in the receive FIFO, isochronous or non-isochronous data packets are ignored and not written to the receive FIFO. Additionally, non-isochronous OUT tokens receive a NAK handshake reply.
  - In all the above three cases, the packet count is not decremented because no data are written to the receive FIFO.

3. When the packet count becomes 0 or when a short packet is received on the endpoint, the NAK bit for that endpoint is set. Once the NAK bit is set, the isochronous or non-isochronous data packets are ignored and not written to the receive FIFO, and non-isochronous OUT tokens receive a NAK handshake reply.
4. After the data are written to the receive FIFO, the application reads the data from the receive FIFO and writes it to external memory, one packet at a time per endpoint.
5. At the end of every packet write on the AHB to external memory, the transfer size for the endpoint is decremented by the size of the written packet.
6. The OUT data transfer completed pattern for an OUT endpoint is written to the receive FIFO on one of the following conditions:
  - The transfer size is 0 and the packet count is 0
  - The last OUT data packet written to the receive FIFO is a short packet ( $0 \leq \text{packet size} < \text{maximum packet size}$ )
7. When either the application pops this entry (OUT data transfer completed), a transfer completed interrupt is generated for the endpoint and the endpoint enable is cleared.

Application programming sequence:

1. Program the OTG\_DOEPTSIZE register for the transfer size and the corresponding packet count.
2. Program the OTG\_DOEPCTL register with the endpoint characteristics, and set the EPENA and CNAK bits.
  - EPENA = 1 in OTG\_DOEPCTL
  - CNAK = 1 in OTG\_DOEPCTL
3. Wait for the RXFLVL interrupt (in OTG\_GINTSTS) and empty the data packets from the receive FIFO.
  - This step can be repeated many times, depending on the transfer size.
4. Asserting the XFRC interrupt (OTG\_DOEPINT) marks a successful completion of the non-isochronous OUT data transfer.
5. Read the OTG\_DOEPTSIZE register to determine the size of the received data payload.

#### • Generic isochronous OUT data transfer

This section describes a regular isochronous OUT data transfer.

Application requirements:

1. All the application requirements for non-isochronous OUT data transfers also apply to isochronous OUT data transfers.
2. For isochronous OUT data transfers, the transfer size and packet count fields must always be set to the number of maximum-packet-size packets that can be received in a single frame and no more. Isochronous OUT data transfers cannot span more than 1 frame.
3. The application must read all isochronous OUT data packets from the receive FIFO (data and status) before the end of the periodic frame (EOPF interrupt in OTG\_GINTSTS).
4. To receive data in the following frame, an isochronous OUT endpoint must be enabled after the EOPF (OTG\_GINTSTS) and before the SOF (OTG\_GINTSTS).

Internal data flow:

1. The internal data flow for isochronous OUT endpoints is the same as that for non-isochronous OUT endpoints, but for a few differences.
2. When an isochronous OUT endpoint is enabled by setting the endpoint enable and clearing the NAK bits, the Even/Odd frame bit must also be set appropriately. The core receives data on an isochronous OUT endpoint in a particular frame only if the following condition is met:
  - EONUM (in OTG\_DOEPCTLx) = FNSOF[0] (in OTG\_DSTS)
3. When the application completely reads an isochronous OUT data packet (data and status) from the receive FIFO, the core updates the RXDPID field in OTG\_DOEPTSIZx with the data PID of the last isochronous OUT data packet read from the receive FIFO.

Application programming sequence:

1. Program the OTG\_DOEPTSIZx register for the transfer size and the corresponding packet count
2. Program the OTG\_DOEPCTLx register with the endpoint characteristics and set the endpoint enable, ClearNAK, and Even/Odd frame bits.
  - EPENA = 1
  - CNAK = 1
  - EONUM = (0: Even/1: Odd)
3. Wait for the RXFLVL interrupt (in OTG\_GINTSTS) and empty the data packets from the receive FIFO
  - This step can be repeated many times, depending on the transfer size.
4. The assertion of the XFRC interrupt (in OTG\_DOEPINTx) marks the completion of the isochronous OUT data transfer. This interrupt does not necessarily mean that the data in memory are good.
5. This interrupt cannot always be detected for isochronous OUT transfers. Instead, the application can detect the INCOMPISOOUT interrupt in OTG\_GINTSTS.
6. Read the OTG\_DOEPTSIZx register to determine the size of the received transfer and to determine the validity of the data received in the frame. The application must treat the data received in memory as valid only if one of the following conditions is met:
  - RXDPID = DATA0 (in OTG\_DOEPTSIZx) and the number of USB packets in which this payload was received = 1
  - RXDPID = DATA1 (in OTG\_DOEPTSIZx) and the number of USB packets in which this payload was received = 2

The number of USB packets in which this payload was received =  
Application programmed initial packet count – core updated final packet count

The application can discard invalid data packets.

#### • Incomplete isochronous OUT data transfers

This section describes the application programming sequence when isochronous OUT data packets are dropped inside the core.

Internal data flow:

1. For isochronous OUT endpoints, the XFRC interrupt (in OTG\_DOEPINTx) may not always be asserted. If the core drops isochronous OUT data packets, the application

may fail to detect the XFRC interrupt (OTG\_DOEPINTx) under the following circumstances:

- When the receive FIFO cannot accommodate the complete ISO OUT data packet, the core drops the received ISO OUT data
  - When the isochronous OUT data packet is received with CRC errors
  - When the isochronous OUT token received by the core is corrupted
  - When the application is very slow in reading the data from the receive FIFO
2. When the core detects an end of periodic frame before transfer completion to all isochronous OUT endpoints, it asserts the incomplete isochronous OUT data interrupt (INCOMPISOOOUT in OTG\_GINTSTS), indicating that an XFRC interrupt (in OTG\_DOEPINTx) is not asserted on at least one of the isochronous OUT endpoints. At this point, the endpoint with the incomplete transfer remains enabled, but no active transfers remain in progress on this endpoint on the USB.

Application programming sequence:

1. Asserting the INCOMPISOOOUT interrupt (OTG\_GINTSTS) indicates that in the current frame, at least one isochronous OUT endpoint has an incomplete transfer.
2. If this occurs because isochronous OUT data is not completely emptied from the endpoint, the application must ensure that the application empties all isochronous OUT data (data and status) from the receive FIFO before proceeding.
  - When all data are emptied from the receive FIFO, the application can detect the XFRC interrupt (OTG\_DOEPINTx). In this case, the application must re-enable the endpoint to receive isochronous OUT data in the next frame.
3. When it receives an INCOMPISOOOUT interrupt (in OTG\_GINTSTS), the application must read the control registers of all isochronous OUT endpoints (OTG\_DOEPCTLx) to determine which endpoints had an incomplete transfer in the current microframe. An endpoint transfer is incomplete if both the following conditions are met:
  - EONUM bit (in OTG\_DOEPCTLx) = FNSOF[0] (in OTG\_DSTS)
  - EPENA = 1 (in OTG\_DOEPCTLx)
4. The previous step must be performed before the SOF interrupt (in OTG\_GINTSTS) is detected, to ensure that the current frame number is not changed.
5. For isochronous OUT endpoints with incomplete transfers, the application must discard the data in the memory and disable the endpoint by setting the EPDIS bit in OTG\_DOEPCTLx.
6. Wait for the EPDISD interrupt (in OTG\_DOEPINTx) and enable the endpoint to receive new data in the next frame.
  - Because the core can take some time to disable the endpoint, the application may not be able to receive the data in the next frame after receiving bad isochronous data.

#### • **Stalling a non-isochronous OUT endpoint**

This section describes how the application can stall a non-isochronous endpoint.

1. Put the core in the Global OUT NAK mode.
2. Disable the required endpoint
  - When disabling the endpoint, instead of setting the SNAK bit in OTG\_DOEPCTL, set STALL = 1 (in OTG\_DOEPCTL).

The STALL bit always takes precedence over the NAK bit.
3. When the application is ready to end the STALL handshake for the endpoint, the STALL bit (in OTG\_DOEPCTLx) must be cleared.
4. If the application is setting or clearing a STALL for an endpoint due to a SetFeature.Endpoint Halt or ClearFeature.Endpoint Halt command, the STALL bit must be set or cleared before the application sets up the status stage transfer on the control endpoint.

## Examples

This section describes and depicts some fundamental transfer types and scenarios.

- Bulk OUT transaction

[Figure 551](#) depicts the reception of a single Bulk OUT data packet from the USB to the AHB and describes the events involved in the process.

**Figure 551. Bulk OUT transaction**

After a SetConfiguration/SetInterface command, the application initializes all OUT endpoints by setting CNAK = 1 and EPENA = 1 (in OTG\_DOEPCTLx), and setting a suitable XFRSIZ and PKTCNT in the OTG\_DOEPSIZx register.

1. host attempts to send data (OUT token) to an endpoint.
2. When the core receives the OUT token on the USB, it stores the packet in the Rx FIFO because space is available there.
3. After writing the complete packet in the Rx FIFO, the core then asserts the RXFLVL interrupt (in OTG\_GINTSTS).
4. On receiving the PKTCNT number of USB packets, the core internally sets the NAK bit for this endpoint to prevent it from receiving any more packets.
5. The application processes the interrupt and reads the data from the Rx FIFO.
6. When the application has read all the data (equivalent to XFERSIZ), the core generates an XFRC interrupt (in OTG\_DOEPINTx).
7. The application processes the interrupt and uses the setting of the XFRC interrupt bit (in OTG\_DOEPINTx) to determine that the intended transfer is complete.

## IN data transfers

### • Packet write

This section describes how the application writes data packets to the endpoint FIFO when dedicated transmit FIFOs are enabled.

1. The application can either choose the polling or the interrupt mode.
  - In polling mode, the application monitors the status of the endpoint transmit data FIFO by reading the OTG\_DTXFSTSx register, to determine if there is enough space in the data FIFO.
  - In interrupt mode, the application waits for the TXFE interrupt (in OTG\_DIEPINTx) and then reads the OTG\_DTXFSTSx register, to determine if there is enough space in the data FIFO.
  - To write a single non-zero length data packet, there must be space to write the entire packet in the data FIFO.
  - To write zero length packet, the application must not look at the FIFO space.
2. Using one of the above mentioned methods, when the application determines that there is enough space to write a transmit packet, the application must first write into the endpoint control register, before writing the data into the data FIFO. Typically, the application, must do a read modify write on the OTG\_DIEPCTLx register to avoid modifying the contents of the register, except for setting the endpoint enable bit.

The application can write multiple packets for the same endpoint into the transmit FIFO, if space is available. For periodic IN endpoints, the application must write packets only for one microframe. It can write packets for the next periodic transaction only after getting transfer complete for the previous transaction.

### • Setting IN endpoint NAK

Internal data flow:

1. When the application sets the IN NAK for a particular endpoint, the core stops transmitting data on the endpoint, irrespective of data availability in the endpoint's transmit FIFO.
2. Non-isochronous IN tokens receive a NAK handshake reply
  - Isochronous IN tokens receive a zero-data-length packet reply
3. The core asserts the INEPNE (IN endpoint NAK effective) interrupt in OTG\_DIEPINTx in response to the SNAK bit in OTG\_DIEPCTLx.
4. Once this interrupt is seen by the application, the application can assume that the endpoint is in IN NAK mode. This interrupt can be cleared by the application by setting the CNAK bit in OTG\_DIEPCTLx.

Application programming sequence:

1. To stop transmitting any data on a particular IN endpoint, the application must set the IN NAK bit. To set this bit, the following field must be programmed.
  - SNAK = 1 in OTG\_DIEPCTLx
2. Wait for assertion of the INEPNE interrupt in OTG\_DIEPINTx. This interrupt indicates that the core has stopped transmitting data on the endpoint.
3. The core can transmit valid IN data on the endpoint after the application has set the NAK bit, but before the assertion of the NAK Effective interrupt.
4. The application can mask this interrupt temporarily by writing to the INEPNEM bit in OTG\_DIEPMSK.
  - INEPNEM = 0 in OTG\_DIEPMSK
5. To exit endpoint NAK mode, the application must clear the NAK status bit (NAKSTS) in OTG\_DIEPCTLx. This also clears the INEPNE interrupt (in OTG\_DIEPINTx).
  - CNAK = 1 in OTG\_DIEPCTLx
6. If the application masked this interrupt earlier, it must be unmasked as follows:
  - INEPNEM = 1 in OTG\_DIEPMSK

- **IN endpoint disable**

Use the following sequence to disable a specific IN endpoint that has been previously enabled.

Application programming sequence:

1. The application must stop writing data on the AHB for the IN endpoint to be disabled.
2. The application must set the endpoint in NAK mode.
  - SNAK = 1 in OTG\_DIEPCTLx
3. Wait for the INEPNE interrupt in OTG\_DIEPINTx.
4. Set the following bits in the OTG\_DIEPCTLx register for the endpoint that must be disabled.
  - EPDIS = 1 in OTG\_DIEPCTLx
  - SNAK = 1 in OTG\_DIEPCTLx
5. Assertion of the EPDISD interrupt in OTG\_DIEPINTx indicates that the core has completely disabled the specified endpoint. Along with the assertion of the interrupt, the core also clears the following bits:
  - EPENA = 0 in OTG\_DIEPCTLx
  - EPDIS = 0 in OTG\_DIEPCTLx
6. The application must read the OTG\_DIEPTSIZx register for the periodic IN EP, to calculate how much data on the endpoint were transmitted on the USB.
7. The application must flush the data in the endpoint transmit FIFO, by setting the following fields in the OTG\_GRSTCTL register:
  - TXFNUM (in OTG\_GRSTCTL) = Endpoint transmit FIFO number
  - TXFFLSH in (OTG\_GRSTCTL) = 1

The application must poll the OTG\_GRSTCTL register, until the TXFFLSH bit is cleared by the core, which indicates the end of flush operation. To transmit new data on this endpoint, the application can re-enable the endpoint at a later point.

#### • Transfer Stop Programming for IN endpoints

The application must use the following programming sequence to stop any transfers (because of an interrupt from the host, typically a reset).

##### Sequence of operations:

1. Disable the IN endpoint by setting:
  - EPDIS = 1 in all OTG\_DIEPCTLx registers
2. Wait for the EPDIS interrupt in OTG\_DIEPINTx, which indicates that the IN endpoint is completely disabled. When the EPDIS interrupt is asserted the following bits are cleared:
  - EPDIS = 0 in OTG\_DIEPCTLx
  - EPENA = 0 in OTG\_DIEPCTLx
3. Flush the Tx FIFO by programming the following bits:
  - TXFFLSH = 1 in OTG\_GRSTCTL
  - TXFNUM = "FIFO number specific to endpoint" in OTG\_GRSTCTL
4. The application can start polling till TXFFLSH in OTG\_GRSTCTL is cleared. When this bit is cleared, it ensures that there is no data left in the Tx FIFO.

#### • Generic non-periodic IN data transfers

Application requirements:

1. Before setting up an IN transfer, the application must ensure that all data to be transmitted as part of the IN transfer are part of a single buffer.
2. For IN transfers, the transfer size field in the endpoint transfer size register denotes a payload that constitutes multiple maximum-packet-size packets and a single short packet. This short packet is transmitted at the end of the transfer.
  - To transmit a few maximum-packet-size packets and a short packet at the end of the transfer:  

$$\text{Transfer size}[\text{EPNUM}] = x \times \text{MPSIZ}[\text{EPNUM}] + \text{sp}$$
 If ( $\text{sp} > 0$ ), then  $\text{packet count}[\text{EPNUM}] = x + 1$ .  
 Otherwise,  $\text{packet count}[\text{EPNUM}] = x$
  - To transmit a single zero-length data packet:  

$$\text{Transfer size}[\text{EPNUM}] = 0$$

$$\text{Packet count}[\text{EPNUM}] = 1$$
  - To transmit a few maximum-packet-size packets and a zero-length data packet at the end of the transfer, the application must split the transfer into two parts. The first sends maximum-packet-size data packets and the second sends the zero-length data packet alone.  
 First transfer:  $\text{transfer size}[\text{EPNUM}] = x \times \text{MPSIZ}[\text{epnum}]$ ;  $\text{packet count} = n$ ;  
 Second transfer:  $\text{transfer size}[\text{EPNUM}] = 0$ ;  $\text{packet count} = 1$ ;
3. Once an endpoint is enabled for data transfers, the core updates the transfer size register. At the end of the IN transfer, the application must read the transfer size register to determine how much data posted in the transmit FIFO have already been sent on the USB.
4. Data fetched into transmit FIFO = Application-programmed initial transfer size – core-updated final transfer size
  - Data transmitted on USB = (application-programmed initial packet count – core updated final packet count)  $\times$  MPSIZ[EPNUM]
  - Data yet to be transmitted on USB = (Application-programmed initial transfer size – data transmitted on USB)

Internal data flow:

1. The application must set the transfer size and packet count fields in the endpoint-specific registers and enable the endpoint to transmit the data.
2. The application must also write the required data to the transmit FIFO for the endpoint.
3. Every time a packet is written into the transmit FIFO by the application, the transfer size for that endpoint is decremented by the packet size. The data is fetched from the memory by the application, until the transfer size for the endpoint becomes 0. After writing the data into the FIFO, the “number of packets in FIFO” count is incremented (this is a 3-bit count, internally maintained by the core for each IN endpoint transmit FIFO. The maximum number of packets maintained by the core at any time in an IN endpoint FIFO is eight). For zero-length packets, a separate flag is set for each FIFO, without any data in the FIFO.
4. Once the data are written to the transmit FIFO, the core reads them out upon receiving an IN token. For every non-isochronous IN data packet transmitted with an ACK

handshake, the packet count for the endpoint is decremented by one, until the packet count is zero. The packet count is not decremented on a timeout.

5. For zero length packets (indicated by an internal zero length flag), the core sends out a zero-length packet for the IN token and decrements the packet count field.
6. If there are no data in the FIFO for a received IN token and the packet count field for that endpoint is zero, the core generates an "IN token received when Tx FIFO is empty" (ITTXFE) interrupt for the endpoint, provided that the endpoint NAK bit is not set. The core responds with a NAK handshake for non-isochronous endpoints on the USB.
7. The core internally rewinds the FIFO pointers and no timeout interrupt is generated.
8. When the transfer size is 0 and the packet count is 0, the transfer complete (XFRC) interrupt for the endpoint is generated and the endpoint enable is cleared.

Application programming sequence:

1. Program the OTG\_DIEPTSIZE register with the transfer size and corresponding packet count.
2. Program the OTG\_DIEPCTL register with the endpoint characteristics and set the CNAK and EPENA (endpoint enable) bits.
3. When transmitting non-zero length data packet, the application must poll the OTG\_DTXFSTS register (where x is the FIFO number associated with that endpoint) to determine whether there is enough space in the data FIFO. The application can optionally use TXFE (in OTG\_DIEPINT) before writing the data.

- **Generic periodic IN data transfers**

This section describes a typical periodic IN data transfer.

Application requirements:

1. Application requirements 1, 2, 3, and 4 of [Generic non-periodic IN data transfers on page 1799](#) also apply to periodic IN data transfers, except for a slight modification of requirement 2.
  - The application can only transmit multiples of maximum-packet-size data packets or multiples of maximum-packet-size packets, plus a short packet at the end. To

transmit a few maximum-packet-size packets and a short packet at the end of the transfer, the following conditions must be met:

$\text{transfer size}[\text{EPNUM}] = x \times \text{MPSIZ}[\text{EPNUM}] + \text{sp}$

(where  $x$  is an integer  $\geq 0$ , and  $0 \leq \text{sp} < \text{MPSIZ}[\text{EPNUM}]$ )

If ( $\text{sp} > 0$ ),  $\text{packet count}[\text{EPNUM}] = x + 1$

Otherwise,  $\text{packet count}[\text{EPNUM}] = x$ ;

$\text{MCNT}[\text{EPNUM}] = \text{packet count}[\text{EPNUM}]$

- The application cannot transmit a zero-length data packet at the end of a transfer. It can transmit a single zero-length data packet by itself. To transmit a single zero-length data packet:
  - $\text{transfer size}[\text{EPNUM}] = 0$
  - $\text{packet count}[\text{EPNUM}] = 1$
  - $\text{MCNT}[\text{EPNUM}] = \text{packet count}[\text{EPNUM}]$
- 2. The application can only schedule data transfers one frame at a time.
  - $(\text{MCNT} - 1) \times \text{MPSIZ} \leq \text{XFERSIZ} \leq \text{MCNT} \times \text{MPSIZ}$
  - $\text{PKTCNT} = \text{MCNT}$  (in  $\text{OTG\_DIEPTSIZE}$ )
  - If  $\text{XFERSIZ} < \text{MCNT} \times \text{MPSIZ}$ , the last data packet of the transfer is a short packet.
  - Note that:  $\text{MCNT}$  is in  $\text{OTG\_DIEPTSIZE}$ ,  $\text{MPSIZ}$  is in  $\text{OTG\_DIEPCTL}$ ,  $\text{PKTCNT}$  is in  $\text{OTG\_DIEPTSIZE}$  and  $\text{XFERSIZ}$  is in  $\text{OTG\_DIEPTSIZE}$
- 3. The complete data to be transmitted in the frame must be written into the transmit FIFO by the application, before the IN token is received. Even when 1 word of the data to be transmitted per frame is missing in the transmit FIFO when the IN token is received, the core behaves as when the FIFO is empty. When the transmit FIFO is empty:
  - A zero data length packet would be transmitted on the USB for isochronous IN endpoints
  - A NAK handshake would be transmitted on the USB for interrupt IN endpoints

Internal data flow:

1. The application must set the transfer size and packet count fields in the endpoint-specific registers and enable the endpoint to transmit the data.
2. The application must also write the required data to the associated transmit FIFO for the endpoint.
3. Every time the application writes a packet to the transmit FIFO, the transfer size for that endpoint is decremented by the packet size. The data are fetched from application memory until the transfer size for the endpoint becomes 0.
4. When an IN token is received for a periodic endpoint, the core transmits the data in the FIFO, if available. If the complete data payload (complete packet, in dedicated FIFO

mode) for the frame is not present in the FIFO, then the core generates an IN token received when Tx FIFO empty interrupt for the endpoint.

- A zero-length data packet is transmitted on the USB for isochronous IN endpoints
  - A NAK handshake is transmitted on the USB for interrupt IN endpoints
5. The packet count for the endpoint is decremented by 1 under the following conditions:
    - For isochronous endpoints, when a zero- or non-zero-length data packet is transmitted
    - For interrupt endpoints, when an ACK handshake is transmitted
    - When the transfer size and packet count are both 0, the transfer completed interrupt for the endpoint is generated and the endpoint enable is cleared.
  6. At the “Periodic frame Interval” (controlled by PFIVL in OTG\_DCFG), when the core finds non-empty any of the isochronous IN endpoint FIFOs scheduled for the current frame non-empty, the core generates an IISOIXFR interrupt in OTG\_GINTSTS.

Application programming sequence:

1. Program the OTG\_DIEPCTLx register with the endpoint characteristics and set the CNAK and EPENA bits.
2. Write the data to be transmitted in the next frame to the transmit FIFO.
3. Asserting the ITTXFE interrupt (in OTG\_DIEPINTx) indicates that the application has not yet written all data to be transmitted to the transmit FIFO.
4. If the interrupt endpoint is already enabled when this interrupt is detected, ignore the interrupt. If it is not enabled, enable the endpoint so that the data can be transmitted on the next IN token attempt.
5. Asserting the XFRC interrupt (in OTG\_DIEPINTx) with no ITTXFE interrupt in OTG\_DIEPINTx indicates the successful completion of an isochronous IN transfer. A read to the OTG\_DIEPTSIZx register must give transfer size = 0 and packet count = 0, indicating all data were transmitted on the USB.
6. Asserting the XFRC interrupt (in OTG\_DIEPINTx), with or without the ITTXFE interrupt (in OTG\_DIEPINTx), indicates the successful completion of an interrupt IN transfer. A read to the OTG\_DIEPTSIZx register must give transfer size = 0 and packet count = 0, indicating all data were transmitted on the USB.
7. Asserting the incomplete isochronous IN transfer (IISOIXFR) interrupt in OTG\_GINTSTS with none of the aforementioned interrupts indicates the core did not receive at least 1 periodic IN token in the current frame.

#### • Incomplete isochronous IN data transfers

This section describes what the application must do on an incomplete isochronous IN data transfer.

Internal data flow:

1. An isochronous IN transfer is treated as incomplete in one of the following conditions:
  - a) The core receives a corrupted isochronous IN token on at least one isochronous IN endpoint. In this case, the application detects an incomplete isochronous IN transfer interrupt (IISOIXFR in OTG\_GINTSTS).
  - b) The application is slow to write the complete data payload to the transmit FIFO and an IN token is received before the complete data payload is written to the FIFO. In this case, the application detects an IN token received when Tx FIFO empty interrupt in OTG\_DIEPINTx. The application can ignore this interrupt, as it

eventually results in an incomplete isochronous IN transfer interrupt (IISOIXFR in OTG\_GINTSTS) at the end of periodic frame.

The core transmits a zero-length data packet on the USB in response to the received IN token.

2. The application must stop writing the data payload to the transmit FIFO as soon as possible.
3. The application must set the NAK bit and the disable bit for the endpoint.
4. The core disables the endpoint, clears the disable bit, and asserts the endpoint disable interrupt for the endpoint.

Application programming sequence:

1. The application can ignore the IN token received when Tx FIFO empty interrupt in OTG\_DIEPINTx on any isochronous IN endpoint, as it eventually results in an incomplete isochronous IN transfer interrupt (in OTG\_GINTSTS).
2. Assertion of the incomplete isochronous IN transfer interrupt (in OTG\_GINTSTS) indicates an incomplete isochronous IN transfer on at least one of the isochronous IN endpoints.
3. The application must read the endpoint control register for all isochronous IN endpoints to detect endpoints with incomplete IN data transfers.
4. The application must stop writing data to the Periodic Transmit FIFOs associated with these endpoints on the AHB.
5. Program the following fields in the OTG\_DIEPCTLx register to disable the endpoint:
  - SNAK = 1 in OTG\_DIEPCTLx
  - EPDIS = 1 in OTG\_DIEPCTLx
6. The assertion of the endpoint disabled interrupt in OTG\_DIEPINTx indicates that the core has disabled the endpoint.
  - At this point, the application must flush the data in the associated transmit FIFO or overwrite the existing data in the FIFO by enabling the endpoint for a new transfer in the next microframe. To flush the data, the application must use the OTG\_GRSTCTL register.

- **Stalling non-isochronous IN endpoints**

This section describes how the application can stall a non-isochronous endpoint.

Application programming sequence:

1. Disable the IN endpoint to be stalled. Set the STALL bit as well.
2. EPDIS = 1 in OTG\_DIEPCTLx, when the endpoint is already enabled
  - STALL = 1 in OTG\_DIEPCTLx
  - The STALL bit always takes precedence over the NAK bit
3. Assertion of the endpoint disabled interrupt (in OTG\_DIEPINTx) indicates to the application that the core has disabled the specified endpoint.
4. The application must flush the non-periodic or periodic transmit FIFO, depending on the endpoint type. In case of a non-periodic endpoint, the application must re-enable the other non-periodic endpoints that do not need to be stalled, to transmit data.
5. Whenever the application is ready to end the STALL handshake for the endpoint, the STALL bit must be cleared in OTG\_DIEPCTLx.
6. If the application sets or clears a STALL bit for an endpoint due to a SetFeature.Endpoint Halt command or ClearFeature.Endpoint Halt command, the STALL bit must be set or cleared before the application sets up the status stage transfer on the control endpoint.

Special case: stalling the control OUT endpoint

The core must stall IN/OUT tokens if, during the data stage of a control transfer, the host sends more IN/OUT tokens than are specified in the SETUP packet. In this case, the application must enable the ITTXFE interrupt in OTG\_DIEPINTx and the OTEPDIS interrupt in OTG\_DOEPINTx during the data stage of the control transfer, after the core has transferred the amount of data specified in the SETUP packet. Then, when the application receives this interrupt, it must set the STALL bit in the corresponding endpoint control register, and clear this interrupt.

#### 47.16.6 Worst case response time

When the OTG\_FS controller acts as a device, there is a worst case response time for any tokens that follow an isochronous OUT. This worst case response time depends on the AHB clock frequency.

The core registers are in the AHB domain, and the core does not accept another token before updating these register values. The worst case is for any token following an isochronous OUT, because for an isochronous transaction, there is no handshake and the next token may come sooner. This worst case value is 7 PHY clocks when the AHB clock is the same as the PHY clock. When the AHB clock is faster, this value is smaller.

If this worst case condition occurs, the core responds to bulk/interrupt tokens with a NAK and drops isochronous and SETUP tokens. The host interprets this as a timeout condition for SETUP and retries the SETUP packet. For isochronous transfers, the Incomplete isochronous IN transfer interrupt (IISOIXFR) and Incomplete isochronous OUT transfer interrupt (IISOOXFR) inform the application that isochronous IN/OUT packets were dropped.

#### Choosing the value of TRDT in OTG\_GUSBCFG

The value in TRDT (OTG\_GUSBCFG) is the time it takes for the MAC, in terms of PHY clocks after it has received an IN token, to get the FIFO status, and thus the first data from the PFC block. This time involves the synchronization delay between the PHY and AHB clocks. The worst case delay for this is when the AHB clock is the same as the PHY clock. In this case, the delay is 5 clocks.

Once the MAC receives an IN token, this information (token received) is synchronized to the AHB clock by the PFC (the PFC runs on the AHB clock). The PFC then reads the data from the SPRAM and writes them into the dual clock source buffer. The MAC then reads the data out of the source buffer (4 deep).

If the AHB is running at a higher frequency than the PHY, the application can use a smaller value for TRDT (in OTG\_GUSBCFG).

[Figure 552](#) has the following signals:

- `tkn_rcvd`: Token received information from MAC to PFC
- `dsynced_tkn_rcvd`: Doubled sync `tkn_rcvd`, from PCLK to HCLK domain
- `spr_read`: Read to SPRAM
- `spr_addr`: Address to SPRAM
- `spr_rdata`: Read data from SPRAM
- `srcbuf_push`: Push to the source buffer
- `srcbuf_rdata`: Read data from the source buffer. Data seen by MAC

To calculate the value of TRDT, refer to [Table 327: TRDT values](#).

**Figure 552. TRDT max timing case**

### 47.16.7 OTG programming model

The OTG\_FS controller is an OTG device supporting HNP and SRP. When the core is connected to an “A” plug, it is referred to as an A-device. When the core is connected to a “B” plug it is referred to as a B-device. In host mode, the OTG\_FS controller turns off  $V_{BUS}$  to conserve power. SRP is a method by which the B-device signals the A-device to turn on  $V_{BUS}$  power. A device must perform both data-line pulsing and  $V_{BUS}$  pulsing, but a host can detect either data-line pulsing or  $V_{BUS}$  pulsing for SRP. HNP is a method by which the B-device negotiates and switches to host role. In Negotiated mode after HNP, the B-device suspends the bus and reverts to the device role.

#### A-device session request protocol

The application must set the SRP-capable bit in the core USB configuration register. This enables the OTG\_FS controller to detect SRP as an A-device.

Figure 553. A-device SRP

1. DRV\_VBUS =  $V_{BUS}$  drive signal to the PHY  
VBUS\_VALID =  $V_{BUS}$  valid signal from PHY  
A\_VALID = A-peripheral  $V_{BUS}$  level signal to PHY  
D+ = Data plus line  
D- = Data minus line

The following points refer and describe the signal numeration shown in the [Figure 553](#):

1. To save power, the application suspends and turns off port power when the bus is idle by writing the port suspend and port power bits in the host port control and status register.
2. PHY indicates port power off by deasserting the VBUS\_VALID signal.
3. The device must detect SE0 for at least 2 ms to start SRP when  $V_{BUS}$  power is off.
4. To initiate SRP, the device turns on its data line pull-up resistor for 5 to 10 ms. The OTG\_FS controller detects data-line pulsing.
5. The device drives  $V_{BUS}$  above the A-device session valid (2.0 V minimum) for  $V_{BUS}$  pulsing.  
The OTG\_FS controller interrupts the application on detecting SRP. The session

request detected bit is set in Global interrupt status register (SRQINT set in OTG\_GINTSTS).

6. The application must service the session request detected interrupt and turn on the port power bit by writing the port power bit in the host port control and status register. The PHY indicates port power-on by asserting the VBUS\_VALID signal.
7. When the USB is powered, the device connects, completing the SRP process.

### B-device session request protocol

The application must set the SRP-capable bit in the core USB configuration register. This enables the OTG\_FS controller to initiate SRP as a B-device. SRP is a means by which the OTG\_FS controller can request a new session from the host.

**Figure 554. B-device SRP**

1. VBUS\_VALID = V<sub>BUS</sub> valid signal from PHY  
 B\_VALID = B-peripheral valid session to PHY  
 DISCHRG\_VBUS = discharge signal to PHY  
 SESS\_END = session end signal to PHY  
 CHRG\_VBUS = charge V<sub>BUS</sub> signal to PHY  
 DP = Data plus line  
 DM = Data minus line

The following points refer and describe the signal numeration shown in the [Figure 554](#):

1. To save power, the host suspends and turns off port power when the bus is idle. The OTG\_FS controller sets the early suspend bit in the core interrupt register after 3 ms of bus idleness. Following this, the OTG\_FS controller sets the USB suspend bit in the core interrupt register. The OTG\_FS controller informs the PHY to discharge V<sub>BUS</sub>.
2. The PHY indicates the session's end to the device. This is the initial condition for SRP. The OTG\_FS controller requires 2 ms of SE0 before initiating SRP. For a USB 1.1 full-speed serial transceiver, the application must wait until V<sub>BUS</sub> discharges to 0.2 V after BSVLD (in OTG\_GOTGCTL) is deasserted. This discharge

- time can be obtained from the transceiver vendor and varies from one transceiver to another.
3. The OTG\_FS core informs the PHY to speed up  $V_{BUS}$  discharge.
  4. The application initiates SRP by writing the session request bit in the OTG control and status register. The OTG\_FS controller perform data-line pulsing followed by  $V_{BUS}$  pulsing.
  5. The host detects SRP from either the data-line or  $V_{BUS}$  pulsing, and turns on  $V_{BUS}$ . The PHY indicates  $V_{BUS}$  power-on to the device.
  6. The OTG\_FS controller performs  $V_{BUS}$  pulsing. The host starts a new session by turning on  $V_{BUS}$ , indicating SRP success. The OTG\_FS controller interrupts the application by setting the session request success status change bit in the OTG interrupt status register. The application reads the session request success bit in the OTG control and status register.
  7. When the USB is powered, the OTG\_FS controller connects, completing the SRP process.

### A-device host negotiation protocol

HNP switches the USB host role from the A-device to the B-device. The application must set the HNP-capable bit in the core USB configuration register to enable the OTG\_FS controller to perform HNP as an A-device.

**Figure 555. A-device HNP**

1. DPPULLDOWN = signal from core to PHY to enable/disable the pull-down on the DP line inside the PHY.  
DMPULLDOWN = signal from core to PHY to enable/disable the pull-down on the DM line inside the PHY.

The following points refer and describe the signal numeration shown in the [Figure 555](#):

1. The OTG\_FS controller sends the B-device a SetFeature b\_hnp\_enable descriptor to enable HNP support. The B-device's ACK response indicates that the B-device supports HNP. The application must set host Set HNP enable bit in the OTG control

and status register to indicate to the OTG\_FS controller that the B-device supports HNP.

2. When it has finished using the bus, the application suspends by writing the port suspend bit in the host port control and status register.
3. When the B-device observes a USB suspend, it disconnects, indicating the initial condition for HNP. The B-device initiates HNP only when it must switch to the host role; otherwise, the bus continues to be suspended.

The OTG\_FS controller sets the host negotiation detected interrupt in the OTG interrupt status register, indicating the start of HNP.

The OTG\_FS controller deasserts the DM pull down and DM pull down in the PHY to indicate a device role. The PHY enables the OTG\_DP pull-up resistor to indicate a connect for B-device.

The application must read the current mode bit in the OTG control and status register to determine device mode operation.

4. The B-device detects the connection, issues a USB reset, and enumerates the OTG\_FS controller for data traffic.
5. The B-device continues the host role, initiating traffic, and suspends the bus when done.

The OTG\_FS controller sets the early suspend bit in the core interrupt register after 3 ms of bus idleness. Following this, the OTG\_FS controller sets the USB suspend bit in the core interrupt register.

6. In Negotiated mode, the OTG\_FS controller detects the suspend, disconnects, and switches back to the host role. The OTG\_FS controller asserts the DM pull down and DM pull down in the PHY to indicate its assumption of the host role.
7. The OTG\_FS controller sets the connector ID status change interrupt in the OTG interrupt status register. The application must read the connector ID status in the OTG control and status register to determine the OTG\_FS controller operation as an A-device. This indicates the completion of HNP to the application. The application must read the Current mode bit in the OTG control and status register to determine host mode operation.
8. The B-device connects, completing the HNP process.

### **B-device host negotiation protocol**

HNP switches the USB host role from B-device to A-device. The application must set the HNP-capable bit in the core USB configuration register to enable the OTG\_FS controller to perform HNP as a B-device.

Figure 556. B-device HNP

1. DPPULLDOWN = signal from core to PHY to enable/disable the pull-down on the DP line inside the PHY.  
DMPULLDOWN = signal from core to PHY to enable/disable the pull-down on the DM line inside the PHY.

The following points refer and describe the signal numeration shown in the [Figure 556](#):

1. The A-device sends the SetFeature b\_hnp\_enable descriptor to enable HNP support. The OTG\_FS controller's ACK response indicates that it supports HNP. The application must set the device HNP enable bit in the OTG control and status register to indicate HNP support.

The application sets the HNP request bit in the OTG control and status register to indicate to the OTG\_FS controller to initiate HNP.

2. When it has finished using the bus, the A-device suspends by writing the port suspend bit in the host port control and status register.

The OTG\_FS controller sets the Early suspend bit in the core interrupt register after 3 ms of bus idleness. Following this, the OTG\_FS controller sets the USB suspend bit in the core interrupt register.

The OTG\_FS controller disconnects and the A-device detects SE0 on the bus, indicating HNP. The OTG\_FS controller asserts the DP pull down and DM pull down in the PHY to indicate its assumption of the host role.

The A-device responds by activating its OTG\_DP pull-up resistor within 3 ms of detecting SE0. The OTG\_FS controller detects this as a connect.

The OTG\_FS controller sets the host negotiation success status change interrupt in the OTG interrupt status register, indicating the HNP status. The application must read the host negotiation success bit in the OTG control and status register to determine host

negotiation success. The application must read the current Mode bit in the core interrupt register (OTG\_GINTSTS) to determine host mode operation.

3. The application sets the reset bit (PRST in OTG\_HPRT) and the OTG\_FS controller issues a USB reset and enumerates the A-device for data traffic.
4. The OTG\_FS controller continues the host role of initiating traffic, and when done, suspends the bus by writing the port suspend bit in the host port control and status register.
5. In Negotiated mode, when the A-device detects a suspend, it disconnects and switches back to the host role. The OTG\_FS controller deasserts the DP pull down and DM pull down in the PHY to indicate the assumption of the device role.
6. The application must read the current mode bit in the core interrupt (OTG\_GINTSTS) register to determine the host mode operation.
7. The OTG\_FS controller connects, completing the HNP process.

## 48 Debug support (DBG)

### 48.1 Overview

The STM32L47x/L48x/L49x/L4Ax devices are built around a Cortex®-M4 core which contains hardware extensions for advanced debugging features. The debug extensions allow the core to be stopped either on a given instruction fetch (breakpoint) or data access (watchpoint). When stopped, the core's internal state and the system's external state may be examined. Once examination is complete, the core and the system may be restored and program execution resumed.

The debug features are used by the debugger host when connecting to and debugging the STM32L47x/L48x/L49x/L4Ax MCUs.

Two interfaces for debug are available:

- Serial wire
- JTAG debug port

**Figure 557. Block diagram of STM32 MCU and Cortex®-M4-level debug support**

**Note:** The debug features embedded in the Cortex®-M4 core are a subset of the Arm® CoreSight Design Kit.

The Arm® Cortex®-M4 core provides integrated on-chip debug support. It is comprised of:

- SWJ-DP: Serial wire / JTAG debug port
- AHP-AP: AHB access port
- ITM: Instrumentation trace macrocell
- FPB: Flash patch breakpoint
- DWT: Data watchpoint trigger
- TPUI: Trace port unit interface (available on larger packages, where the corresponding pins are mapped)
- ETM: Embedded Trace Macrocell (available only on STM32L47x/L48x/L49x/L4Ax devices larger packages, where the corresponding pins are mapped)

It also includes debug features dedicated to the STM32L47x/L48x/L49x/L4Ax:

- Flexible debug pinout assignment
- MCU debug box (support for low-power modes, control over peripheral clocks, etc.)

*Note:* For further information on debug functionality supported by the Arm® Cortex®-M4 core, refer to the Cortex®-M4-r0p1 Technical Reference Manual and to the CoreSight Design Kit-r0p1 TRM (see [Section 48.2: Reference Arm® documentation](#)).

## 48.3 SWJ debug port (serial wire and JTAG)

The STM32L47x/L48x/L49x/L4Ax core integrates the Serial Wire / JTAG Debug Port (SWJ-DP). It is an Arm® standard CoreSight debug port that combines a JTAG-DP (5-pin) interface and a SW-DP (2-pin) interface.

- The JTAG Debug Port (JTAG-DP) provides a 5-pin standard JTAG interface to the AHP-AP port.
- The Serial Wire Debug Port (SW-DP) provides a 2-pin (clock + data) interface to the AHP-AP port.

In the SWJ-DP, the two JTAG pins of the SW-DP are multiplexed with some of the five JTAG pins of the JTAG-DP.

Figure 558. SWJ debug port

Figure 558 shows that the asynchronous TRACE output (TRACESWO) is multiplexed with TDO. This means that the asynchronous trace can only be used with SW-DP, not JTAG-DP.

### 48.3.1 Mechanism to select the JTAG-DP or the SW-DP

By default, the JTAG-Debug Port is active.

If the debugger host wants to switch to the SW-DP, it must provide a dedicated JTAG sequence on TMS/TCK (respectively mapped to SWDIO and SWCLK) which disables the JTAG-DP and enables the SW-DP. This way it is possible to activate the SWDP using only the SWCLK and SWDIO pins.

This sequence is:

1. Send more than 50 TCK cycles with TMS (SWDIO) = 1
2. Send the 16-bit sequence on TMS (SWDIO) = 0111100111100111 (MSB transmitted first)
3. Send more than 50 TCK cycles with TMS (SWDIO) = 1

## 48.4 Pinout and debug port pins

The STM32L47x/L48x/L49x/L4Ax MCUs are available in various packages with different numbers of available pins. As a result, some functionalities (ETM) related to pin availability may differ between packages.

### 48.4.1 SWJ debug port pins

Five pins are used as outputs from the STM32L47x/L48x/L49x/L4Ax for the SWJ-DP as *alternate functions* of general-purpose I/Os. These pins are available on all packages.

**Table 330. SWJ debug port pins**

| SWJ-DP pin name | JTAG debug port |                          | SW debug port |                                           | Pin assignment |
|-----------------|-----------------|--------------------------|---------------|-------------------------------------------|----------------|
|                 | Type            | Description              | Type          | Debug assignment                          |                |
| JTMS/SWDIO      | I               | JTAG Test Mode Selection | IO            | Serial Wire Data Input/Output             | PA13           |
| JTCK/SWCLK      | I               | JTAG Test Clock          | I             | Serial Wire Clock                         | PA14           |
| JTDI            | I               | JTAG Test Data Input     | -             | -                                         | PA15           |
| JTDO/TRACESWO   | O               | JTAG Test Data Output    | -             | TRACESWO if asynchronous trace is enabled | PB3            |
| NJTRST          | I               | JTAG Test nReset         | -             | -                                         | PB4            |

### 48.4.2 Flexible SWJ-DP pin assignment

After RESET (SYSRESETn or PORESETn), all five pins used for the SWJ-DP are assigned as dedicated pins immediately usable by the debugger host (note that the trace outputs are not assigned except if explicitly programmed by the debugger host).

However, the STM32L47x/L48x/L49x/L4Ax MCUs offer the possibility of disabling some or all of the SWJ-DP ports, and therefore the possibility of releasing the associated pins for general-purpose I/O (GPIO) usage, except for NJTRST that can be left disconnected but cannot be used as general purpose GPIO without losing debugger connection. For more details on how to disable SWJ-DP port pins, please refer to [Section 8.4.2: I/O pin alternate function multiplexer and mapping](#).

**Table 331. Flexible SWJ-DP pin assignment**

| Available debug ports                         | SWJ IO pin assigned |                     |             |            |              |
|-----------------------------------------------|---------------------|---------------------|-------------|------------|--------------|
|                                               | PA13 / JTMS / SWDIO | PA14 / JTCK / SWCLK | PA15 / JTDI | PB3 / JTDO | PB4 / NJTRST |
| Full SWJ (JTAG-DP + SW-DP) - Reset State      | X                   | X                   | X           | X          | X            |
| Full SWJ (JTAG-DP + SW-DP) but without NJTRST | X                   | X                   | X           | X          |              |
| JTAG-DP disabled and SW-DP enabled            | X                   | X                   |             |            |              |
| JTAG-DP disabled and SW-DP disabled           | Released            |                     |             |            |              |

### 48.4.3 Internal pull-up and pull-down on JTAG pins

It is necessary to ensure that the JTAG input pins are not floating since they are directly connected to flip-flops to control the debug mode features. Special care must be taken with the SWCLK/TCK pin which is directly connected to the clock of some of these flip-flops.

To avoid any uncontrolled IO levels, the device embeds internal pull-ups and pull-downs on the JTAG input pins:

- NJTRST: internal pull-up
- JTDI: internal pull-up
- JTMS/SWDIO: internal pull-up
- TCK/SWCLK: internal pull-down

Once a JTAG IO is released by the user software, the GPIO controller takes control again. The reset states of the GPIO control registers put the I/Os in the equivalent state:

- NJTRST: input pull-up
- JTDI: input pull-up
- JTMS/SWDIO: input pull-up
- JTCK/SWCLK: input pull-down
- JTDO: input floating

The software can then use these I/Os as standard GPIOs.

*Note: The JTAG IEEE standard recommends to add pull-ups on TDI, TMS and nTRST but there is no special recommendation for TCK. However, for JTCK, the device needs an integrated pull-down.*

*Having embedded pull-ups and pull-downs removes the need to add external resistors.*

#### 48.4.4 Using serial wire and releasing the unused debug pins as GPIOs

To use the serial wire DP to release some GPIOs, the user software must change the GPIO (PA15, PB3 and PB4) configuration mode in the GPIO\_MODER register. This releases PA15, PB3 and PB4 which now become available as GPIOs.

When debugging, the host performs the following actions:

- Under system reset, all SWJ pins are assigned (JTAG-DP + SW-DP).
- Under system reset, the debugger host sends the JTAG sequence to switch from the JTAG-DP to the SW-DP.
- Still under system reset, the debugger sets a breakpoint on vector reset.
- The system reset is released and the Core halts.
- All the debug communications from this point are done using the SW-DP. The other JTAG pins can then be reassigned as GPIOs by the user software.

*Note:* For user software designs, note that:

*To release the debug pins, remember that they will be first configured either in input-pull-up (nTRST, TMS, TDI) or pull-down (TCK) or output tristate (TDO) for a certain duration after reset until the instant when the user software releases the pins.*

*When debug pins (JTAG or SW or TRACE) are mapped, changing the corresponding IO pin configuration in the IOPORT controller has no effect.*

#### 48.5 STM32L47x/L48x/L49x/L4Ax JTAG TAP connection

The STM32L47x/L48x/L49x/L4Ax MCUs integrate two serially connected JTAG TAPs, the boundary scan TAP (IR is 5-bit wide) and the Cortex®-M4 TAP (IR is 4-bit wide).

To access the TAP of the Cortex®-M4 for debug purposes:

1. First, it is necessary to shift the BYPASS instruction of the boundary scan TAP.
2. Then, for each IR shift, the scan chain contains 9 bits (=5+4) and the unused TAP instruction must be shifted by using the BYPASS instruction.
3. For each data shift, the unused TAP, which is in BYPASS mode, adds 1 extra data bit in the data scan chain.

*Note:* **Important:** Once Serial-Wire is selected using the dedicated Arm® JTAG sequence, the boundary scan TAP is automatically disabled (JTMS forced high).

Figure 559. JTAG TAP connections

## 48.6 ID codes and locking mechanism

There are several ID codes inside the STM32L47x/L48x/L49x/L4Ax MCUs. ST strongly recommends tools designers to lock their debuggers using the MCU DEVICE ID code located in the external PPB memory map at address 0xE0042000.

## 48.6.1 MCU device ID code

The STM32L47x/L48x/L49x/L4Ax MCUs integrate an MCU ID code. This ID identifies the ST MCU part-number and the die revision. It is part of the DBG\_MCU component and is mapped on the external PPB bus (see [Section 48.16 on page 1832](#)). This code is accessible using the JTAG debug port (4 to 5 pins) or the SW debug port (two pins) or by the user software. It is even accessible while the MCU is under system reset.

Only the DEV\_ID(11:0) should be used for identification by the debugger/programmer tools.

### DBGMCU\_IDCODE

Address: 0xE004 2000

Only 32-bits access supported. Read-only

Bits 31:16 **REV\_ID[15:0]** Revision identifier

This field indicates the revision of the device.

For STM32L47x/L48x devices

0x1000: Rev 1

0x1001: Rev 2

0x1003: Rev 3

0x1007: Rev 4

For STM32L49x/L4Ax devices

0x1000: Rev A

0x2000: Rev B

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **DEV\_ID[11:0]**: Device identifier

The device ID is:

0x461 for STM32L49x/L4Ax devices

0x415 for STM32L47x/L48x devices.

## 48.6.2 Boundary scan TAP

### JTAG ID code

The TAP of the STM32L47x/L48x/L49x/L4Ax BSC (boundary scan) integrates a JTAG ID code equal to 0x06415041.

## 48.6.3 Cortex<sup>®</sup>-M4 TAP

The TAP of the Arm<sup>®</sup> Cortex<sup>®</sup>-M4 integrates a JTAG ID code. This ID code is the Arm<sup>®</sup> default one and has not been modified. This code is only accessible by the JTAG Debug Port.

This code is **0x4BA00477** (corresponds to Cortex®-M4 r0p1, see [Section 48.2: Reference Arm® documentation](#)).

#### 48.6.4 Cortex®-M4 JEDEC-106 ID code

The Arm® Cortex®-M4 integrates a JEDEC-106 ID code. It is located in the 4KB ROM table mapped on the internal PPB bus at address 0xE00FF000\_0xE00FFFFF.

This code is accessible by the JTAG Debug Port (4 to 5 pins) or by the SW Debug Port (two pins) or by the user software.

### 48.7 JTAG debug port

A standard JTAG state machine is implemented with a 4-bit instruction register (IR) and five data registers (for full details, refer to the Cortex®-M4 with FPU r0p1 *Technical Reference Manual (TRM)*, for references, please see [Section 48.2: Reference Arm® documentation](#)).

**Table 332. JTAG debug port data registers**

## 48.8 SW debug port

### 48.8.1 SW protocol introduction

This synchronous serial protocol uses two pins:

- SWCLK: clock from host to target
- SWDIO: bidirectional

The protocol allows two banks of registers (DPACC registers and APACC registers) to be read and written to.

Bits are transferred LSB-first on the wire.

For SWDIO bidirectional management, the line must be pulled-up on the board (100 kΩ recommended by Arm®).

Each time the direction of SWDIO changes in the protocol, a turnaround time is inserted where the line is not driven by the host nor the target. By default, this turnaround time is one bit time, however this can be adjusted by configuring the SWCLK frequency.

### 48.8.2 SW protocol sequence

Each sequence consist of three phases:

1. Packet request (8 bits) transmitted by the host
2. Acknowledge response (3 bits) transmitted by the target
3. Data transfer phase (33 bits) transmitted by the host or the target

**Table 334. Packet request (8-bits)**

| Bit | Name   | Description                                                                      |
|-----|--------|----------------------------------------------------------------------------------|
| 0   | Start  | Must be “1”                                                                      |
| 1   | APnDP  | 0: DP Access<br>1: AP Access                                                     |
| 2   | RnW    | 0: Write Request<br>1: Read Request                                              |
| 4:3 | A(3:2) | Address field of the DP or AP registers (refer to <a href="#">Table 333</a> )    |
| 5   | Parity | Single bit parity of preceding bits                                              |
| 6   | Stop   | 0                                                                                |
| 7   | Park   | Not driven by the host. Must be read as “1” by the target because of the pull-up |

Refer to the Cortex®-M4 r0p1 *TRM* for a detailed description of DPACC and APACC registers.

The packet request is always followed by the turnaround time (default 1 bit) where neither the host nor target drive the line.

Table 335. ACK response (3 bits)

| Bit  | Name | Description                        |
|------|------|------------------------------------|
| 0..2 | ACK  | 001: FAULT<br>010: WAIT<br>100: OK |

The ACK Response must be followed by a turnaround time only if it is a READ transaction or if a WAIT or FAULT acknowledge has been received.

Table 336. DATA transfer (33 bits)

| Bit   | Name           | Description                       |
|-------|----------------|-----------------------------------|
| 0..31 | WDATA or RDATA | Write or Read data                |
| 32    | Parity         | Single parity of the 32 data bits |

The DATA transfer must be followed by a turnaround time only if it is a READ transaction.

### 48.8.3 SW-DP state machine (reset, idle states, ID code)

The State Machine of the SW-DP has an internal ID code which identifies the SW-DP. It follows the JEP-106 standard. This ID code is the default Arm<sup>®</sup> one and is set to **0x1BA01477** (corresponding to Cortex<sup>®</sup>-M4 r0p1).

*Note:* *Note that the SW-DP state machine is inactive until the target reads this ID code.*

- The SW-DP state machine is in RESET STATE either after power-on reset, or after the DP has switched from JTAG to SWD or after the line is high for more than 50 cycles
- The SW-DP state machine is in IDLE STATE if the line is low for at least two cycles after RESET state.
- After RESET state, it is **mandatory** to first enter into an IDLE state AND to perform a READ access of the DP-SW ID CODE register. Otherwise, the target will issue a FAULT acknowledge response on another transactions.

Further details of the SW-DP state machine can be found in the *Cortex<sup>®</sup>-M4 r0p1 TRM* and the *CoreSight Design Kit r0p1 TRM*.

### 48.8.4 DP and AP read/write accesses

- Read accesses to the DP are not posted: the target response can be immediate (if ACK=OK) or can be delayed (if ACK=WAIT).
- Read accesses to the AP are posted. This means that the result of the access is returned on the next transfer. If the next access to be done is NOT an AP access, then the DP-RDBUFF register must be read to obtain the result.  
The READOK flag of the DP-CTRL/STAT register is updated on every AP read access or RDBUFF read request to know if the AP read access was successful.
- The SW-DP implements a write buffer (for both DP or AP writes), that enables it to accept a write operation even when other transactions are still outstanding. If the write buffer is full, the target acknowledge response is "WAIT". With the exception of

IDCODE read or CTRL/STAT read or ABORT write which are accepted even if the write buffer is full.

- Because of the asynchronous clock domains SWCLK and HCLK, two extra SWCLK cycles are needed after a write transaction (after the parity bit) to make the write effective internally. These cycles should be applied while driving the line low (IDLE state)  
This is particularly important when writing the CTRL/STAT for a power-up request. If the next transaction (requiring a power-up) occurs immediately, it will fail.

#### 48.8.5 SW-DP registers

Access to these registers are initiated when APnDP=0

**Table 337. SW-DP registers**

| A(3:2) | R/W        | CTRLSEL bit of SELECT register | Register     | Notes                                                                                                                                                                                                                                                                                                    |
|--------|------------|--------------------------------|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 00     | Read       | -                              | IDCODE       | The manufacturer code is not set to ST code <b>0x2BA01477</b> (identifies the SW-DP)                                                                                                                                                                                                                     |
| 00     | Write      | -                              | ABORT        | -                                                                                                                                                                                                                                                                                                        |
| 01     | Read/Write | 0                              | DP-CTRL/STAT | Purpose is to: <ul style="list-style-type: none"> <li>– request a system or debug power-up</li> <li>– configure the transfer operation for AP accesses</li> <li>– control the pushed compare and pushed verify operations.</li> <li>– read some status flags (overrun, power-up acknowledges)</li> </ul> |
| 01     | Read/Write | 1                              | WIRE CONTROL | Purpose is to configure the physical serial port protocol (like the duration of the turnaround time)                                                                                                                                                                                                     |
| 10     | Read       | -                              | READ RESEND  | Enables recovery of the read data from a corrupted debugger transfer, without repeating the original AP transfer.                                                                                                                                                                                        |
| 10     | Write      | -                              | SELECT       | The purpose is to select the current access port and the active 4-words register window                                                                                                                                                                                                                  |
| 11     | Read/Write | -                              | READ BUFFER  | This read buffer is useful because AP accesses are posted (the result of a read AP request is available on the next AP transaction).<br>This read buffer captures data from the AP, presented as the result of a previous read, without initiating a new transaction                                     |

### 48.8.6 SW-AP registers

Access to these registers are initiated when APnDP=1

There are many AP Registers (see AHB-AP) addressed as the combination of:

- The shifted value A[3:2]
- The current value of the DP SELECT register

## 48.9 AHB-AP (AHB access port) - valid for both JTAG-DP and SW-DP

### Features:

- System access is independent of the processor status.
- Either SW-DP or JTAG-DP accesses AHB-AP.
- The AHB-AP is an AHB master into the Bus Matrix. Consequently, it can access all the data buses (Dcode Bus, System Bus, internal and external PPB bus) but the ICode bus.
- Bitband transactions are supported.
- AHB-AP transactions bypass the FPB.

The address of the 32-bits AHB-AP registers are 6-bits wide (up to 64 words or 256 bytes) and consists of:

- c) Bits [7:4] = the bits [7:4] APBANKSEL of the DP SELECT register
- d) Bits [3:2] = the 2 address bits of A[3:2] of the 35-bit packet request for SW-DP.

The AHB-AP of the Cortex<sup>®</sup>-M4 includes 9 x 32-bits registers:

**Table 338. Cortex<sup>®</sup>-M4 AHB-AP registers**

| Address offset | Register name                  | Notes                                                                                                                         |
|----------------|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| 0x00           | AHB-AP Control and Status Word | Configures and controls transfers through the AHB interface (size, hprot, status on current transfer, address increment type) |
| 0x04           | AHB-AP Transfer Address        | -                                                                                                                             |
| 0x0C           | AHB-AP Data Read/Write         | -                                                                                                                             |
| 0x10           | AHB-AP Banked Data 0           | Directly maps the 4 aligned data words without rewriting the Transfer Address Register.                                       |
| 0x14           | AHB-AP Banked Data 1           |                                                                                                                               |
| 0x18           | AHB-AP Banked Data 2           |                                                                                                                               |
| 0x1C           | AHB-AP Banked Data 3           |                                                                                                                               |
| 0xF8           | AHB-AP Debug ROM Address       | Base Address of the debug interface                                                                                           |
| 0xFC           | AHB-AP ID Register             | -                                                                                                                             |

Refer to the Cortex<sup>®</sup>-M4 *r0p1 TRM* for further details.

## 48.10 Core debug

Core debug is accessed through the core debug registers. Debug access to these registers is by means of the *Advanced High-performance Bus* (AHB-AP) port. The processor can access these registers directly over the internal *Private Peripheral Bus* (PPB).

It consists of 4 registers:

**Table 339. Core debug registers**

| Register | Description                                                                                                                                                                                            |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DHCSR    | The 32-bit Debug Halting Control and Status Register:<br>This provides status information about the state of the processor enable core debug halt and step the processor.                              |
| DCRSR    | The 17-bit Debug Core Register Selector Register:<br>This selects the processor register to transfer data to or from.                                                                                  |
| DCRDR    | The 32-bit Debug Core Register Data Register:<br>This holds data for reading and writing registers to and from the processor selected by the DCRSR (Selector) register.                                |
| DEMCR    | The 32-bit Debug Exception and Monitor Control Register:<br>This provides Vector Catching and Debug Monitor Control. This register contains a bit named <b>TRCENA</b> which enable the use of a TRACE. |

*Note:* **Important:** these registers are not reset by a system reset. They are only reset by a power-on reset.

Refer to the *Cortex®-M4 r0p1 TRM* for further details.

To Halt on reset, it is necessary to:

- enable the bit0 (VC\_CORRESET) of the Debug and Exception Monitor Control Register
- enable the bit0 (C\_DEBUGEN) of the Debug Halting Control and Status Register.

## 48.11 Capability of the debugger host to connect under system reset

The STM32L47x/L48x/L49x/L4Ax MCUs' reset system comprises the following reset sources:

- POR (power-on reset) which asserts a RESET at each power-up
- Internal watchdog reset
- Software reset
- External reset.

The Cortex®-M4 differentiates the reset of the debug part (generally PORRESETn) and the other one (SYSRESETn).

This way, it is possible for the debugger to connect under System Reset, programming the Core Debug Registers to halt the core when fetching the reset vector. Then the host can release the system reset and the core will immediately halt without having executed any instructions. In addition, it is possible to program any debug features under System Reset.

*Note:* It is highly recommended for the debugger host to connect (set a breakpoint in the reset vector) under system reset.

## 48.12 FPB (Flash patch breakpoint)

The FPB unit:

- implements hardware breakpoints
- patches code and data from code space to system space. This feature gives the possibility to correct software bugs located in the Code Memory Space.

The use of a Software Patch or a Hardware Breakpoint is exclusive.

The FPB consists of:

- 2 literal comparators for matching against literal loads from Code Space and remapping to a corresponding area in the System Space
- 6 instruction comparators for matching against instruction fetches from Code Space. They can be used either to remap to a corresponding area in the System Space or to generate a Breakpoint Instruction to the core.

## 48.13 DWT (data watchpoint trigger)

The DWT unit consists of four comparators. They are configurable as:

- a hardware watchpoint or
- a trigger to an ETM or
- a PC sampler or
- a data address sampler

The DWT also provides some means to give some profiling informations. For this, some counters are accessible to give the number of:

- Clock cycle
- Folded instructions
- Load store unit (LSU) operations
- Sleep cycles
- CPI (clock per instructions)
- Interrupt overhead

## 48.14 ITM (instrumentation trace macrocell)

### 48.14.1 General description

The ITM is an application-driven trace source that supports *printf* style debugging to trace *Operating System* (OS) and application events, and emits diagnostic system information. The ITM emits trace information as packets which can be generated as:

- **Software trace.** Software can write directly to the ITM stimulus registers to emit packets.
- **Hardware trace.** The DWT generates these packets, and the ITM emits them.
- **Time stamping.** Timestamps are emitted relative to packets. The ITM contains a 21-bit counter to generate the timestamp. The Cortex<sup>®</sup>-M4 clock or the bit clock rate of the *Serial Wire Viewer* (SWV) output clocks the counter.

The packets emitted by the ITM are output to the TPIU (Trace Port Interface Unit). The formatter of the TPIU adds some extra packets (refer to TPIU) and then output the complete packets sequence to the debugger host.

The bit TRCEN of the Debug Exception and Monitor Control Register must be enabled before you program or use the ITM.

### 48.14.2 Time stamp packets, synchronization and overflow packets

Time stamp packets encode time stamp information, generic control and synchronization. It uses a 21-bit timestamp counter (with possible prescalers) which is reset at each time stamp packet emission. This counter can be either clocked by the CPU clock or the SWV clock.

A synchronization packet consists of 6 bytes equal to 0x80\_00\_00\_00\_00\_00 which is emitted to the TPIU as 00 00 00 00 00 80 (LSB emitted first).

A synchronization packet is a timestamp packet control. It is emitted at each DWT trigger.

For this, the DWT must be configured to trigger the ITM: the bit CYCCNTENA (bit0) of the DWT Control Register must be set. In addition, the bit2 (SYNCENA) of the ITM Trace Control Register must be set.

*Note:* If the SYNENA bit is not set, the DWT generates Synchronization triggers to the TPIU which will send only TPIU synchronization packets and not ITM synchronization packets.

An overflow packet consists is a special timestamp packets which indicates that data has been written but the FIFO was full.

**Table 340. Main ITM registers**

| Address   | Register        | Details                                                            |
|-----------|-----------------|--------------------------------------------------------------------|
| @E0000FB0 | ITM lock access | Write 0xC5ACCE55 to unlock Write Access to the other ITM registers |

Table 340. Main ITM registers (continued)

| Address                | Register                     | Details                                                                                                                                                  |
|------------------------|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|

| @E0000000-<br>E000007C | Stimulus port registers 0-31 | Write the 32-bits data on the selected Stimulus Port (32 available) to be traced out                                                                     |

### Example of configuration

To output a simple value to the TPIU:

- Configure the TPIU and assign TRACE I/Os by configuring the DBGMCU\_CR (refer to [Section 48.17.2: TRACE pin assignment](#) and [Section 48.16.3: Debug MCU configuration register \(DBGMCU\\_CR\)](#))
- Write 0xC5ACCE55 to the ITM Lock Access Register to unlock the write access to the ITM registers
- Write 0x00010005 to the ITM Trace Control Register to enable the ITM with Synchronous enabled and an ATB ID different from 0x00
- Write 0x1 to the ITM Trace Enable Register to enable the Stimulus Port 0
- Write 0x1 to the ITM Trace Privilege Register to unmask Stimulus Ports 7:0
- Write the value to output in the Stimulus Port Register 0: this can be done by software (using a printf function)

## 48.15 ETM (Embedded trace macrocell)

### 48.15.1 General description

The ETM enables the reconstruction of program execution. Data are traced using the Data Watchpoint and Trace (DWT) component or the Instruction Trace Macrocell (ITM) whereas instructions are traced using the Embedded Trace Macrocell (ETM).

The ETM transmits information as packets and is triggered by embedded resources. These resources must be programmed independently and the trigger source is selected using the Trigger Event Register (0xE0041008). An event could be a simple event (address match from an address comparator) or a logic equation between 2 events. The trigger source is one of the four comparators of the DWT module. The following events can be monitored:

- Clock cycle matching
- Data address matching

For more informations on the trigger resources refer to [Section 48.13: DWT \(data watchpoint trigger\)](#).

The packets transmitted by the ETM are output to the TPIU (Trace Port Interface Unit). The formatter of the TPIU adds some extra packets (refer to [Section 48.17: TPIU \(trace port interface unit\)](#)) and then outputs the complete packet sequence to the debugger host.

### 48.15.2 Signal protocol, packet types

This part is described in the section 7 ETMv3 Signal Protocol of the Arm® IHI 0014N document.

### 48.15.3 Main ETM registers

For more information on registers refer to the chapter 3 of the Arm® IHI 0014N specification.

**Table 341. Main ETM registers**

| Address    | Register                 | Details                                                                                                |
|------------|--------------------------|--------------------------------------------------------------------------------------------------------|
| 0xE0041FB0 | ETM Lock Access          | Write 0xC5ACCE55 to unlock the write access to the other ETM registers.                                |
| 0xE0041000 | ETM Control              | This register controls the general operation of the ETM, for instance how tracing is enabled.          |
| 0xE0041010 | ETM Status               | This register provides information about the current status of the trace and trigger logic.            |
| 0xE0041008 | ETM Trigger Event        | This register defines the event that will control trigger.                                             |
| 0xE004101C | ETM Trace Enable Control | This register defines which comparator is selected.                                                    |
| 0xE0041020 | ETM Trace Enable Event   | This register defines the trace enabling event.                                                        |
| 0xE0041024 | ETM Trace Start/Stop     | This register defines the traces used by the trigger source to start and stop the trace, respectively. |

#### 48.15.4 Configuration example

To output a simple value to the TPIU:

- Configure the TPIU and enable the I/O\_TRACEN to assign TRACE I/Os in the STM32L47x/L48x/L49x/L4Ax debug configuration register
- Write 0xC5ACCE55 to the ETM Lock Access Register to unlock the write access to the ITM registers
- Write 0x00001D1E to the control register (configure the trace)
- Write 0000406F to the Trigger Event register (define the trigger event)
- Write 0000006F to the Trace Enable Event register (define an event to start/stop)
- Write 00000001 to the Trace Start/stop register (enable the trace)
- Write 0000191E to the ETM Control Register (end of configuration)

### 48.16 MCU debug component (DBGMCU)

The MCU debug component helps the debugger provide support for:

- Low-power modes
- Clock control for timers, watchdog, I<sup>2</sup>C and bxCAN during a breakpoint
- Control of the trace pins assignment

#### 48.16.1 Debug support for low-power modes

To enter low-power mode, the instruction WFI or WFE must be executed.

The MCU implements several low-power modes which can either deactivate the CPU clock or reduce the power of the CPU.

The core does not allow FCLK or HCLK to be turned off during a debug session. As these are required for the debugger connection, during a debug, they must remain active. The MCU integrates special means to allow the user to debug software in low-power modes.

For this, the debugger host must first set some debug configuration registers to change the low-power mode behavior:

- In Sleep mode, DBG\_SLEEP bit of DBGMCU\_CR register must be previously set by the debugger. This will feed HCLK with the same clock that is provided to FCLK (system clock previously configured by the software).
- In Stop mode, the bit DBG\_STOP must be previously set by the debugger. This will enable the internal RC oscillator clock to feed FCLK and HCLK in Stop mode.
- In Standby mode, the bit DBG\_STANDBY must be previously set by the debugger. This will keep the regulators on, and enable the internal RC oscillator clock to feed FCLK and HCLK in Standby mode. A system reset is generated internally so that exiting from Standby is identical than fetching from reset.

The DBGMCU\_CR register can be written by the debugger under system reset. If the debugger host does not support these features, it is still possible to write this register by software.

### 48.16.2 Debug support for timers, RTC, watchdog, bxCAN and I<sup>2</sup>C

During a breakpoint, it is necessary to choose how the counter of timers, RTC and watchdog should behave:

- They can continue to count inside a breakpoint. This is usually required when a PWM is controlling a motor, for example.
- They can stop to count inside a breakpoint. This is required for watchdog purposes.

For the bxCAN, the user can choose to block the update of the receive register during a breakpoint.

For the I<sup>2</sup>C, the user can choose to block the SMBUS timeout during a breakpoint.

The DBGMCU freeze registers can be written by the debugger under system reset. If the debugger host does not support these features, it is still possible to write these registers by software.

### 48.16.3 Debug MCU configuration register (DBGMCU\_CR)

Address: 0xE004 2004

Power-on reset: 0x0000 0000

System reset: not affected

Access: Only 32-bit access supported

|      |      |      |      |      |      |      |      |                  |      |            |      |      |             |          |           |

| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | TRACE_MODE [1:0] |      | TRACE_IOEN | Res. | Res. | DBG_STANDBY | DBG_STOP | DBG_SLEEP |
|      |      |      |      |      |      |      |      | rw               | rw   | rw         |      |      | rw          | rw       | rw        |

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:5 **TRACE\_MODE[1:0] and TRACE\_IOEN**: Trace pin assignment control

– With TRACE\_IOEN=0:

TRACE\_MODE=xx: TRACE pins not assigned (default state)

– With TRACE\_IOEN=1:

- TRACE\_MODE=00: TRACE pin assignment for Asynchronous Mode
- TRACE\_MODE=01: TRACE pin assignment for Synchronous Mode with a TRACEDATA size of 1
- TRACE\_MODE=10: TRACE pin assignment for Synchronous Mode with a TRACEDATA size of 2
- TRACE\_MODE=11: TRACE pin assignment for Synchronous Mode with a TRACEDATA size of 4

Bits 4:3 Reserved, must be kept at reset value.

**Bit 2 DBG\_STANDBY:** Debug Standby mode

0: (FCLK=Off, HCLK=Off) The whole digital part is unpowered.

From software point of view, exiting from Standby is identical than fetching reset vector (except a few status bit indicated that the MCU is resuming from Standby)

1: (FCLK=On, HCLK=On) In this case, the digital part is not unpowered and FCLK and HCLK are provided by the internal RC oscillator which remains active. In addition, the MCU generate a system reset during Standby mode so that exiting from Standby is identical than fetching from reset.

**Bit 1 DBG\_STOP:** Debug Stop mode

0: (FCLK=Off, HCLK=Off) In STOP mode, the clock controller disables all clocks (including HCLK and FCLK). When exiting from STOP mode, the clock configuration is identical to the one after RESET (CPU clocked by the 8 MHz internal RC oscillator (HSI16)). Consequently, the software must reprogram the clock controller to enable the PLL, the Xtal, etc.

1: (FCLK=On, HCLK=On) In this case, when entering STOP mode, FCLK and HCLK are provided by the internal RC oscillator which remains active in STOP mode. When exiting STOP mode, the software must reprogram the clock controller to enable the PLL, the Xtal, etc. (in the same way it would do in case of DBG\_STOP=0)

**Bit 0 DBG\_SLEEP:** Debug Sleep mode

0: (FCLK=On, HCLK=Off) In Sleep mode, FCLK is clocked by the system clock as previously configured by the software while HCLK is disabled.

In Sleep mode, the clock controller configuration is not reset and remains in the previously programmed state. Consequently, when exiting from Sleep mode, the software does not need to reconfigure the clock controller.

1: (FCLK=On, HCLK=On) In this case, when entering Sleep mode, HCLK is fed by the same clock that is provided to FCLK (system clock as previously configured by the software).

**48.16.4 Debug MCU APB1 freeze register1(DBGMCU\_APB1FZR1)**

Address: 0xE004 2008

Power on reset (POR): 0x0000 0000

System reset: not affected

Access: Only 32-bit access are supported.

 1: The I2C2 SMBus timeout is frozen
- Bit 21 **DBG\_I2C1\_STOP**: I2C1 SMBUS timeout counter stopped when core is halted  
 0: Same behavior as in normal mode  
 1: The I2C1 SMBus timeout is frozen
- Bits 20:13 Reserved, must be kept at reset value.
- Bit 12 **DBG\_IWDG\_STOP**: Independent watchdog counter stopped when core is halted  
 0: The independent watchdog counter clock continues even if the core is halted  
 1: The independent watchdog counter clock is stopped when the core is halted
- Bit 11 **DBG\_WWDG\_STOP**: Window watchdog counter stopped when core is halted  
 0: The window watchdog counter clock continues even if the core is halted  
 1: The window watchdog counter clock is stopped when the core is halted
- Bit 10 **DBG\_RTC\_STOP**: RTC counter stopped when core is halted  
 0: The clock of the RTC counter is fed even if the core is halted  
 1: The clock of the RTC counter is stopped when the core is halted
- Bits 9:6 Reserved, must be kept at reset value.
- Bit 5 **DBG\_TIM7\_STOP**: TIM7 counter stopped when core is halted  
 0: The counter clock of TIM7 is fed even if the core is halted  
 1: The counter clock of TIM7 is stopped when the core is halted
- Bit 4 **DBG\_TIM6\_STOP**: TIM6 counter stopped when core is halted  
 0: The counter clock of TIM6 is fed even if the core is halted  
 1: The counter clock of TIM6 is stopped when the core is halted
- Bit 3 **DBG\_TIM5\_STOP**: TIM5 counter stopped when core is halted  
 0: The counter clock of TIM5 is fed even if the core is halted  
 1: The counter clock of TIM5 is stopped when the core is halted

- Bit 2 **DBG\_TIM4\_STOP**: TIM4 counter stopped when core is halted  
 0: The counter clock of TIM4 is fed even if the core is halted  
 1: The counter clock of TIM4 is stopped when the core is halted
- Bit 1 **DBG\_TIM3\_STOP**: TIM3 counter stopped when core is halted  
 0: The counter clock of TIM3 is fed even if the core is halted  
 1: The counter clock of TIM3 is stopped when the core is halted
- Bit 0 **DBG\_TIM2\_STOP**: TIM2 counter stopped when core is halted  
 0: The counter clock of TIM2 is fed even if the core is halted  
 1: The counter clock of TIM2 is stopped when the core is halted

#### 48.16.5 Debug MCU APB1 freeze register 2 (DBGMCU\_APB1FZR2)

Address: 0xE004 200C

Power on reset (POR): 0x0000 0000

System reset: not affected

Access: Only 32-bit access are supported.

Bit 16 **DBG\_TIM15\_STOP**: TIM15 counter stopped when core is halted

0: The clock of the TIM15 counter is fed even if the core is halted

1: The clock of the TIM15 counter is stopped when the core is halted

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **DBG\_TIM8\_STOP**: TIM8 counter stopped when core is halted

0: The clock of the TIM8 counter is fed even if the core is halted

1: The clock of the TIM8 counter is stopped when the core is halted

Bit 12 Reserved, must be kept at reset value.

Bit 11 **DBG\_TIM1\_STOP**: TIM1 counter stopped when core is halted

0: The clock of the TIM1 counter is fed even if the core is halted

1: The clock of the TIM1 counter is stopped when the core is halted

Bits 10:0 Reserved, must be kept at reset value.

## 48.17 TPIU (trace port interface unit)

### 48.17.1 Introduction

The TPIU acts as a bridge between the on-chip trace data from the ITM and the ETM.

The output data stream encapsulates the trace source ID, that is then captured by a *trace port analyzer* (TPA).

The core embeds a simple TPIU, especially designed for low-cost debug (consisting of a special version of the CoreSight TPIU).

**Figure 560. TPIU block diagram**

### 48.17.2 TRACE pin assignment

- Asynchronous mode  
The asynchronous mode requires 1 extra pin and is available on all packages. It is only available if using Serial Wire mode (not in JTAG mode).

**Table 342. Asynchronous TRACE pin assignment**

| TPUI pin name | Trace synchronous mode |                                | STM32L47x/L48x/<br>L49x/L4Ax pin<br>assignment |
|---------------|------------------------|--------------------------------|------------------------------------------------|
|               | Type                   | Description                    |                                                |
| TRACESWO      | O                      | TRACE Asynchronous Data Output | PB3                                            |

- Synchronous mode  
The synchronous mode requires from 2 to 6 extra pins depending on the data trace size and is only available in the larger packages. In addition it is available in JTAG mode and in Serial Wire mode and provides better bandwidth output capabilities than asynchronous trace.

Table 343. Synchronous TRACE pin assignment

| TPUI pin name | Trace synchronous mode |                                                     | STM32L47x/L48x/<br>L49x/L4Ax pin<br>assignment   |
|---------------|------------------------|-----------------------------------------------------|--------------------------------------------------|
|               | Type                   | Description                                         |                                                  |
| TRACECK       | O                      | TRACE Clock                                         | PE2                                              |
| TRACED[3:0]   | O                      | TRACE Synchronous Data Outputs<br>Can be 1, 2 or 4. | PE[6:3]<br>PC1, PC8, PD2,<br>PC12 <sup>(1)</sup> |

1. PC1, PC8, PD2, PC12 only for STM32L49x/L4Ax devices

### TPUI TRACE pin assignment

By default, these pins are NOT assigned. They can be assigned by setting the TRACE\_IOEN and TRACE\_MODE bits in the [Debug MCU configuration register \(DBGMCU\\_CR\)](#). This configuration has to be done by the debugger host.

In addition, the number of pins to assign depends on the trace configuration (asynchronous or synchronous).

- **Asynchronous mode:** 1 extra pin is needed
- **Synchronous mode:** from 2 to 5 extra pins are needed depending on the size of the data trace port register (1, 2 or 4) :
  - TRACECK
  - TRACED(0) if port size is configured to 1, 2 or 4
  - TRACED(1) if port size is configured to 2 or 4
  - TRACED(2) if port size is configured to 4
  - TRACED(3) if port size is configured to 4

To assign the TRACE pin, the debugger host must program the bits TRACE\_IOEN and TRACE\_MODE[1:0] of the [Debug MCU configuration register \(DBGMCU\\_CR\)](#). By default the TRACE pins are not assigned.

This register is mapped on the external PPB and is reset by the PORESET (and not by the SYSTEM reset). It can be written by the debugger under SYSTEM reset.

Table 344. Flexible TRACE pin assignment

| DBGMCU_CR register |                  | Pins assigned for:       | TRACE IO pin assigned   |               |                                       |                                       |                                       |                                        |
|--------------------|------------------|--------------------------|-------------------------|---------------|---------------------------------------|---------------------------------------|---------------------------------------|----------------------------------------|

| 1                  | 10               | Synchronous Trace 2 bit |                         | TRACECK       | TRACED[0]                             | TRACED[1]                             | -                                     | -                                      |
| 1                  | 11               | Synchronous Trace 4 bit |                         | TRACECK       | TRACED[0]                             | TRACED[1]                             | TRACED[2]                             | TRACED[3]                              |

1. Only for STM32L49x/L4Ax devices.

2. When Serial Wire mode is used, it is released, but when JTAG is used, it is assigned to JTDO.

**Note:** By default, the TRACECLKIN input clock of the TPIU is tied to GND. It is assigned to HCLK two clock cycles after the bit TRACE\_IOEN has been set.

The debugger must then program the Trace Mode by writing the PROTOCOL[1:0] bits in the SPP\_R (Selected Pin Protocol) register of the TPIU.

- PROTOCOL=00: Trace Port Mode (synchronous)
- PROTOCOL=01 or 10: Serial Wire (Manchester or NRZ) Mode (asynchronous mode). Default state is 01

It then also configures the TRACE port size by writing the bits [3:0] in the CPSPS\_R (Current Synchronous Port Size Register) of the TPIU:

- 0x1 for 1 pin (default state)
- 0x2 for 2 pins
- 0x8 for 4 pins

### 48.17.3 TPUI formatter

The formatter protocol outputs data in 16-byte frames:

- seven bytes of data
- eight bytes of mixed-use bytes consisting of:
  - 1 bit (LSB) to indicate it is a DATA byte ('0') or an ID byte ('1').
  - 7 bits (MSB) which can be data or change of source ID trace.
- one byte of auxiliary bits where each bit corresponds to one of the eight mixed-use bytes:
  - if the corresponding byte was a data, this bit gives bit0 of the data.
  - if the corresponding byte was an ID change, this bit indicates when that ID change takes effect.

**Note:** Refer to the Arm<sup>®</sup> CoreSight Architecture Specification v1.0 (Arm IHI 0029B) for further information

#### 48.17.4 TPUI frame synchronization packets

The TPUI can generate two types of synchronization packets:

- The Frame Synchronization packet (or Full Word Synchronization packet)  
It consists of the word: 0x7F\_FF\_FF\_FF (LSB emitted first). This sequence can not occur at any other time provided that the ID source code 0x7F has not been used.  
It is output periodically **between** frames.  
In continuous mode, the TPA must discard all these frames once a synchronization frame has been found.
- The Half-Word Synchronization packet  
It consists of the half word: 0x7F\_FF (LSB emitted first).  
It is output periodically **between or within** frames.  
These packets are only generated in continuous mode and enable the TPA to detect that the TRACE port is in IDLE mode (no TRACE to be captured). When detected by the TPA, it must be discarded.

#### 48.17.5 Transmission of the synchronization frame packet

There is no Synchronization Counter register implemented in the TPIU of the core. Consequently, the synchronization trigger can only be generated by the **DWT**. Refer to the registers DWT Control Register (bits SYNCTAP[11:10]) and the DWT Current PC Sampler Cycle Count Register.

The TPUI Frame synchronization packet (0x7F\_FF\_FF\_FF) is emitted:

- after each TPIU reset release. This reset is synchronously released with the rising edge of the TRACECLKIN clock. This means that this packet is transmitted when the TRACE\_IOEN bit in the DBGMCU\_CFG register is set. In this case, the word 0x7F\_FF\_FF\_FF is not followed by any formatted packet.
- at each DWT trigger (assuming DWT has been previously configured). Two cases occur:
  - If the bit SYNENA of the ITM is reset, only the word 0x7F\_FF\_FF\_FF is emitted without any formatted stream which follows.
  - If the bit SYNENA of the ITM is set, then the ITM synchronization packets will follow (0x80\_00\_00\_00\_00\_00), formatted by the TPUI (trace source ID added).

#### 48.17.6 Synchronous mode

The trace data output size can be configured to 4, 2 or 1 pin: TRACED(3:0)

The output clock is output to the debugger (TRACECK)

Here, TRACECLKIN is driven internally and is connected to HCLK only when TRACE is used.

*Note:* In this synchronous mode, it is not required to provide a stable clock frequency.

The TRACE I/Os (including TRACECK) are driven by the rising edge of TRACLKIN (equal to HCLK). Consequently, the output frequency of TRACECK is equal to HCLK/2.

### 48.17.7 Asynchronous mode

This is a low cost alternative to output the trace using only 1 pin: this is the asynchronous output pin TRACESWO. Obviously there is a limited bandwidth.

TRACESWO is multiplexed with JTDO when using the SW-DP pin. This way, this functionality is available in all STM32L47x/L48x/L49x/L4Ax packages.

This asynchronous mode requires a constant frequency for TRACECLKIN. For the standard UART (NRZ) capture mechanism, 5% accuracy is needed. The Manchester encoded version is tolerant up to 10%.

### 48.17.8 TRACECLKIN connection inside the STM32L47x/L48x/L49x/L4Ax

In the STM32L47x/L48x/L49x/L4Ax, this TRACECLKIN input is internally connected to HCLK. This means that when in asynchronous trace mode, the application is restricted to use time frames where the CPU frequency is stable.

*Note:* **Important:** when using asynchronous trace: it is important to be aware that:

*The default clock of the STM32L47x/L48x/L49x/L4Ax MCUs is the internal RC oscillator. Its frequency under reset is different from the one after reset release. This is because the RC calibration is the default one under system reset and is updated at each system reset release.*

*Consequently, the trace port analyzer (TPA) should not enable the trace (with the TRACE\_IOEN bit) under system reset, because a Synchronization Frame Packet will be issued with a different bit time than trace packets which will be transmitted after reset release.*

### 48.17.9 TPIU registers

The TPIU APB registers can be read and written only if the bit TRCENA of the Debug Exception and Monitor Control Register (DEMCR) is set. Otherwise, the registers are read as zero (the output of this bit enables the PCLK of the TPIU).

**Table 345. Important TPIU registers**

| Address    | Register                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| 0xE0040304 | Formatter and flush control | Bit 31-9 = always '0'<br>Bit 8 = TrgIn = always '1' to indicate that triggers are indicated<br>Bit 7-4 = always 0<br>Bit 3-2 = always 0<br>Bit 1 = EnFCont. In Synchronous Trace mode (Select_Pin_Protocol register bit1:0 = 00), this bit is forced to '1': the formatter is automatically enabled in continuous mode. In asynchronous mode (Select_Pin_Protocol register bit1:0 <> 00), this bit can be written to activate or not the formatter.<br>Bit 0 = always '0'<br>The resulting default value is 0x102<br><b>Note:</b> In synchronous mode, because the TRACECTL pin is not mapped outside the chip, the formatter is always enabled in continuous mode; this way the formatter inserts some control packets to identify the source of the trace packets). |
| 0xE0040300 | Formatter and flush status  | Not used in Cortex®-M4, always read as 0x00000008                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

#### 48.17.10 Example of configuration

- Set the bit TRCENA in the Debug Exception and Monitor Control Register (DEMCR)
- Write the TPIU Current Port Size Register to the desired value (default is 0x1 for a 1-bit port size)
- Write TPIU Formatter and Flush Control Register to 0x102 (default value)
- Write the TPIU Select Pin Protocol to select the synchronous or asynchronous mode. Example: 0x2 for asynchronous NRZ mode (UART like)
- Write the DBGMCU control register to 0x20 (bit IO\_TRACEN) to assign TRACE I/Os for asynchronous mode. A TPIU Synchronous packet is emitted at this time (FF\_FF\_FF\_7F)
- Configure the ITM and write the ITM Stimulus register to output a value

## 48.18 DBG register map

The following table summarizes the Debug registers

### Table 346. DBG register map and reset values

1. The reset value is product dependent. For more information, refer to [Section 48.6.1: MCU device ID code](#).

## 49 Device electronic signature

The device electronic signature is stored in the System memory area of the Flash memory module, and can be read using the debug interface or by the CPU. It contains factory-programmed identification and calibration data that allow the user firmware or other external devices to automatically match to the characteristics of the STM32L47x/L48x/L49x/L4Ax microcontroller.

### 49.1 Unique device ID register (96 bits)

The unique device identifier is ideally suited:

- for use as serial numbers (for example USB string serial numbers or other end applications)
- for use as part of the security keys in order to increase the security of code in Flash memory while using and combining this unique ID with software cryptographic primitives and protocols before programming the internal Flash memory
- to activate secure boot processes, etc.

The 96-bit unique device identifier provides a reference number which is unique for any device and in any context. These bits cannot be altered by the user.

Base address: 0x1FFF 7590

Address offset: 0x00

Read only = 0xFFFF XXXX where X is factory-programmed

Bits 31:0 **UID[31:0]**: X and Y coordinates on the wafer

Address offset: 0x04

Read only = 0xXXXX XXXX where X is factory-programmed

|            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31         | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

Bits 31:0 **UID[95:64]:** LOT\_NUM[55:24]

Lot number (ASCII encoded)

## 49.2 Flash size data register

Base address: 0x1FFF 75E0

Address offset: 0x00

Read only = 0xXXXX where X is factory-programmed

|            |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|------------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 15         | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| FLASH_SIZE |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| r          | r  | r  | r  | r  | r  | r | r | r | r | r | r | r | r | r | r |

Bits 15:0 **FLASH\_SIZE[15:0]:** Flash memory size

This bitfield indicates the size of the device Flash memory expressed in Kbytes.

As an example, 0x040 corresponds to 64 Kbytes.

49.3 Package data register

Base address: 0x1FFF 7500  
Address offset: 0x00  
Read only = 0xXXXX where X is factory-programmed

## 50 Important security notice

The STMicroelectronics group of companies (ST) places a high value on product security, which is why the ST product(s) identified in this documentation may be certified by various security certification bodies and/or may implement our own security measures as set forth herein. However, no level of security certification and/or built-in security measures can guarantee that ST products are resistant to all forms of attacks. As such, it is the responsibility of each of ST's customers to determine if the level of security provided in an ST product meets the customer needs both in relation to the ST product alone, as well as when combined with other components and/or software for the customer end product or application. In particular, take note that:

- ST products may have been certified by one or more security certification bodies, such as Platform Security Architecture ([www.psacertified.org](http://www.psacertified.org)) and/or Security Evaluation standard for IoT Platforms ([www.trustcb.com](http://www.trustcb.com)). For details concerning whether the ST product(s) referenced herein have received security certification along with the level and current status of such certification, either visit the relevant certification standards website or go to the relevant product page on [www.st.com](http://www.st.com) for the most up to date information. As the status and/or level of security certification for an ST product can change from time to time, customers should re-check security certification status/level as needed. If an ST product is not shown to be certified under a particular security standard, customers should not assume it is certified.
- Certification bodies have the right to evaluate, grant and revoke security certification in relation to ST products. These certification bodies are therefore independently responsible for granting or revoking security certification for an ST product, and ST does not take any responsibility for mistakes, evaluations, assessments, testing, or other activity carried out by the certification body with respect to any ST product.
- Industry-based cryptographic algorithms (such as AES, DES, or MD5) and other open standard technologies which may be used in conjunction with an ST product are based on standards which were not developed by ST. ST does not take responsibility for any flaws in such cryptographic algorithms or open technologies or for any methods which have been or may be developed to bypass, decrypt or crack such algorithms or technologies.
- While robust security testing may be done, no level of certification can absolutely guarantee protections against all attacks, including, for example, against advanced attacks which have not been tested for, against new or unidentified forms of attack, or against any form of attack when using an ST product outside of its specification or intended use, or in conjunction with other components or software which are used by customer to create their end product or application. ST is not responsible for resistance against such attacks. As such, regardless of the incorporated security features and/or any information or support that may be provided by ST, each customer is solely responsible for determining if the level of attacks tested for meets their needs, both in relation to the ST product alone and when incorporated into a customer end product or application.
- All security features of ST products (inclusive of any hardware, software, documentation, and the like), including but not limited to any enhanced security features added by ST, are provided on an "AS IS" BASIS. AS SUCH, TO THE EXTENT PERMITTED BY APPLICABLE LAW, ST DISCLAIMS ALL WARRANTIES, EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO THE IMPLIED WARRANTIES OF MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE, unless the applicable written and signed contract terms specifically provide otherwise.
